INTRODUCTION

TO THE ARTICLES RELATING TO ORGANIC CHEMISTRY

THE names used to denote ring formulæ are given below for convenience of reference

Since the publication of the last volume I have been assisted in the work of reading and making abstracts of original memoirs by Drs T Cooksey, T A Lawson, Samuel Rideal, Messrs J Wilkie, G N Huntly, J T Norman, and D A Louis I have also been assisted by Mr Arthur G Green and Mr Cecil W Cunningham in the work of revising the proof sheets I have great pleasure in thanking these gentlemen for the energetic and efficient manner in which they have carried out their share of the work

H FORSTER MORLEY

Nomenclature of Ring Formulæ

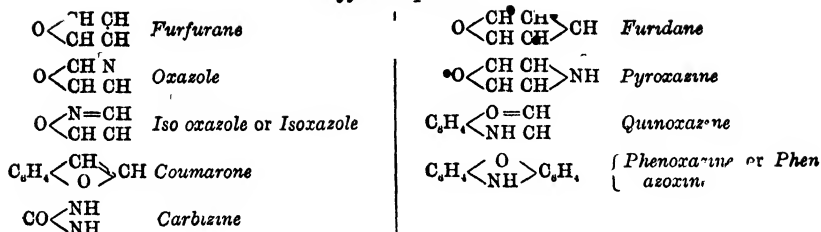

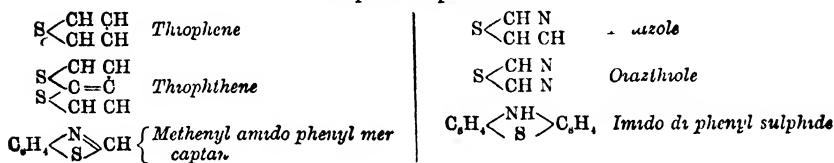

Hydrocarbons

$\text{CH} \begin{smallmatrix} \text{CH}_2 \\ \text{CH}_2 \end{smallmatrix}$ Trimethylene	$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \\ \text{CH} \end{smallmatrix} \text{CH}$ Indonaphthene
$\text{CH} \begin{smallmatrix} \text{CH} \\ \text{CH} \end{smallmatrix} \text{CH}_2$ Tetramethylene	$\text{CH} \begin{smallmatrix} \text{CH} \\ \text{CH} \end{smallmatrix} \text{CH}$ Tetramethenyl
$\text{CH} \begin{smallmatrix} \text{CH} \text{CH}_2 \\ \text{CH} \text{CH}_2 \end{smallmatrix}$ Pentamethylene	$\text{CH} \begin{smallmatrix} \text{CH} \text{CH} \\ \text{CH} \text{CH} \end{smallmatrix}$ Pentamethenyl hydride

Nitrogen compounds

$\text{NH} \begin{smallmatrix} \text{CH} \text{CH} \\ \text{CH} \text{CH} \end{smallmatrix}$ Pyrrole	$\text{N} \begin{smallmatrix} \text{CH} \text{CH} \\ \text{CH} \text{CH} \end{smallmatrix} \text{CH}$ Puridine
$\text{NH} \begin{smallmatrix} \diagup \text{CH} \\ \diagdown \text{CH} \end{smallmatrix}$ Pyrrolole	$\text{N} \begin{smallmatrix} \diagup \text{CH} \\ \diagdown \text{CH} \end{smallmatrix} \text{CH}$ Puridazole
$\text{NH} \begin{smallmatrix} \text{CH} \text{N} \\ \text{CH} \text{CH} \end{smallmatrix}$ Glitoxaline	$\text{N} \begin{smallmatrix} \text{CH} \text{CH} \\ \text{CH} \text{CH} \end{smallmatrix} \text{N}$ Pyrazine
$\text{N} \begin{smallmatrix} \text{CH} \text{N} \\ \text{CH} \text{CH} \end{smallmatrix}$ Metapyrrole	$\text{N} \begin{smallmatrix} \text{CH} \text{N} \\ \text{CH} \text{CH} \end{smallmatrix} \text{CH}$ Pyrimidine
$\text{NH} \begin{smallmatrix} \text{CH} \text{N} \\ \text{CH} \text{N} \end{smallmatrix}$ or $\text{N} \begin{smallmatrix} \text{CH} \text{N} \\ \text{CH} \text{N} \end{smallmatrix}$ Triazole	$\text{N} \begin{smallmatrix} \text{CH} \text{N} \\ \text{CH} \text{N} \end{smallmatrix} \text{CH}$ Triazole
$\text{NH} \begin{smallmatrix} \diagup \text{CH} \\ \diagdown \text{CH} \end{smallmatrix}$ Osotriazole	$\text{N} \begin{smallmatrix} \diagup \text{N} \\ \diagdown \text{CH} \end{smallmatrix} \text{CH}$ Osotriazole
$\text{NH} \begin{smallmatrix} \text{N}=\text{N} \\ \text{CH} \text{N} \end{smallmatrix}$ Tetrazole	$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \text{CH} \\ \text{N}=\text{CH} \end{smallmatrix}$ Quinoline
$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \\ \text{NH} \end{smallmatrix} \text{CH}$ Indole	$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \text{CH} \\ \text{CH} \text{N} \end{smallmatrix}$ Isquinoline
$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \\ \text{N} \end{smallmatrix} \text{NH}$ Indazine	$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{N} \text{CH} \\ \text{N} \text{CH} \end{smallmatrix}$ Quinoxaline
$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \\ \text{NH} \end{smallmatrix} \text{N}$ Pseudo indazine	$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \text{N} \\ \text{N}=\text{CH} \end{smallmatrix}$ Quinoxaline
$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \\ \text{N} \end{smallmatrix} \text{C}_6\text{H}_4$ Acridine	$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \text{CH} \\ \text{N}=\text{N} \end{smallmatrix}$ Cumuline
$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{N} \\ \text{N} \end{smallmatrix} \text{C}_6\text{H}_4$ Phenazine

II TERMS AND QUANTITIES, &C, FREQUENTLY USED

Aq	Water, e.g. NaOHAq means an aqueous solution of caustic soda
aq	18 parts by weight of water
A'	} Residues of mono, di, and tri basic acids. Thus, in describing the salts of a monobasic acid NaA', CaA', AlA', may be written, HA' standing for the acid. For a dibasic acid we should write Na ₂ A'', CaA'', Al ₂ A'', &c
A''	
B' B'' &c	
	Stand for bases of the ammonia type, in describing their salts. Thus the hydrochloride would be B'HCl or B''2HCl, according as the base is monacid or diacid, &c
conc	Concentrated.
dil.	Dilute
g	gram
mgm.	milligram.
mm	millimetre.
mol	molecule
oil	liquid nearly, or quite, insoluble in water
pp	precipitate
to ppt	to precipitate.
ppg	precipitating
ppd.	precipitated.

ABBREVIATIONS.

xi

sol	soluble in.
insol	insoluble in
v e sol	very easily
v sol	very
m sol	moderately
sl. sol	slightly
v sl & l	very slightly
v	see
cf	compare
c	about
[°]	a melting point
(°)	a boiling point
H	Hardness (of minerals).
At w	Atomic weight
Mol w or	Molecular weight.
D	Density
cor	corrected
uncor	uncorrected
v	in vapour
V D	vapour density, i.e. density of a gas compared with hydrogen or air
S G	Specific gravity compared with water
S G $\frac{10}{15}$	" " at 10 compared with water at 0°
S G $\frac{15}{4}$	" " " 15° " " " 4°
S G $\frac{12}{1}$	" " " 12°, compared with water of which the temperature is not given
S H	Specific heat
S H v	" " of a gas at constant volume
S H p	" " " " " pressure
H C	Quantity of heat, in gram units, produced during the complete combustion of the mass of a solid or liquid body represented by its formula, taken in grams
H C v	Heat of combustion in gram units of a gram molecule of an element or compound, when gaseous, under constant volume
H C p	The same, under constant pressure
H F	Quantity of heat, in gram units, produced during the formation of the mass of a solid or liquid body represented by its formula, taken in grams, from the masses of its constituent elements expressed by their formulae, taken in grams
H F v	Heat of formation of a gram molecule of a gaseous compound from the gram molecules of its elements under constant volume
H F p	The same, under constant pressure
H V	Heat of vaporisation of a liquid, i.e. gram units of heat required to change a gram molecule of the liquid compound at B P into gas at same temperature and pressure
T C	Thermal conductivity (unit to be stated)
S V	Specific volume, or the molecular weight of a gaseous compound divided by the S G of the liquid compound at its boiling point compared with water at 4°
S.V.S	Specific volume of a solid, or the mass of the solid expressed by its formula, taken in grams, divided by its S G
E C	Electrical conductivity (the unit is stated in each case)
C E (10° to 20°)	Coefficient of expansion (between 10° and 20°)
S	Solubility in water
S (alcohol)	" " alcohol
μ , &c	Index of refraction for hydrogen line B
$R_{\frac{1}{2}}$	" " " sodium " D, &c
R_{∞}	Molecular refraction for sodium light, i.e. index of refraction for line D minus one, multiplied by molecular weight, and divided by S G at 15° compared with water at 0°
R_{∞}	The same, S.G. being determined at 15°-20° and referred to water at 4°
[a] _D	Cauchy's formula (Bruhl's R_{λ})
[a]	Specific rotation for sodium light
[a]	" " " neutral light $[a] = \frac{100}{p} \times \frac{a}{d}$ a = observed rotation for 100 mm of liquid. d = S.G. of liquid. p = no of grammes of active substance in 100 grammes of liquid

M M	Molecular magnetic rotatory power = $\frac{m \times \alpha}{d' \times m'}$, where m = molecular weight of the body of S G = d , α = angle of rotation under magnetic influence, α' = angle of rotation of water under same influence, and m' = molecular weight of water (18)
Ac . .	Acetyl C_2H_5O
Bz . .	Benzoyl C_6H_5O
Cy . .	Cyanogen CN
Et . .	Ethyl C_2H_5
Me . .	Methyl CH_3
Ph . .	Phenyl C_6H_5
Pr . .	Normal Propyl $CH_2CH_2CH_3$
Pr . .	Isopropyl $CH(CH_3)_2$
R, R' etc	Alcohol radicles or alkyls
prim	primary
sec	secondary
tert	tertiary
n	normal
m, o, p .	meta—ortho—para
c	consecutive
i	irregular
s	symmetrical
u	unsymmetrical,
ψ	pseudo
v	attached to nitrogen
α	Employed to denote that the substituent is attached to a carbon atom which is next, next but one, or next but two, respectively, to the terminal carbon atom. The end to be reckoned from is determined by the nature of the compound. Thus $CH_3CHBrCO_2H$ is α bromo propionic acid
β	
γ	
ω	denotes that the element or radicle which follows it is attached to a terminal carbon atom
α, β, γ , etc	indicate position in an open chain, only
1, 2, 3, etc	indicate position in a ring only
(α), (β), etc	Used when α, β , &c are employed in a sense different from the above, e.g. (α) dibromo camphor
(B)	Baeyer's Nomenclature
(Py)	benzene ring
	pyridine ring
	Thus (B 1 3) dichloroquinoline, means a meta dichloroquinoline in which the chlorine atoms are both in the benzene ring
	While (Py 1 3) dichloroquinoline, means a similar body, only the chlorine atoms are in the pyridine ring. The numbers are counted from two carbon atoms which are in different rings, but both united to the same carbon atom
(A)	denotes the central ring in the molecule of anthracene, acridines, and azines
exo	means that the element or radicle it precedes is in a closed ring
exo-	" " " " not in a benzene ring
allo	denotes isomerism that is not indicated by ordinary formulæ, thus maleic acid may be called <i>allo</i> -fumaric acid
thio	denotes displacement of oxygen by sulphur
sulpho	" the group SO_2H , except in the word sulphocyanide
sulphydro-	" the group SH
	Tribromonitrobenzene sulphonic acid {1 2 3 4 5} means that the three bromines occupy positions 1, 2, and 3, the nitro group the position 4, and the sulpho group the position 5

* Denotes that the formula to which it is affixed has not been determined by analysis. But it by no means follows that formulæ without this mark are those of analysed compounds.

All temperatures are given in degrees Centigrade unless when specially stated otherwise.

Wave lengths are given in 10^{-7} mm.

Formulæ, when used instead of names of substances, have a qualitative meaning only.

Thomsen's notation is used in thermochemical data.

DICTIONARY OF CHEMISTRY.

INDIGO CARBOXYLIC ACID *v* INDIGO

INDIGO-ARMINE *v* INDIGO

INDIGO-SULPHONIC ACID *v* INDIGO

INDIGOTINE *v* INDIGO

INDIGO-WHITE *v* INDIGO

INDILEUCINE *v* INDIGO

INDIN $C_{16}H_{16}N_4O_2$ Formed by the action of potash upon isatyde, thio isatyde, or di thio isatyde, formed also by heating isatin (Laurent, *A Ch* [3] 3, 471) Obtained also by boiling a solution of dioxindole in glycerin for a long time (Knop, *Z* 1865, 273) Deep rose coloured powder or minute needles Insol water, *v* sl sol alcohol and ether Dissolves in H_2SO_4 , forming a red solution, whence it is ppd unchanged by water A solution in concentrated alcoholic KOH deposits black crystals, apparently either $C_{16}H_{16}KN_4O_2$ or, more probably, potassium indate $C_{16}H_{16}KN_4O_2$.

Di bromo-indin $C_{16}H_{16}Br_2N_4O$ Formed by the action of bromine on indin or on di thio isatyde (Laurent) Formed also by heating di bromo isatyde at 220° (Erdmann *J pr* 22, 265) Violet black powder, sl sol alcohol

Di chloro-indin $C_{16}H_{16}Cl_2N_4O_2$ Obtained by heating di chloro isatyde either alone or with alcoholic potash (E) Dirty violet powder, insol water, alcohol, and $HClAq$ Forms a yellowish solution in $KOHAq$ from which HCl ppts yellow flakes

Tetra chloro indin $C_{16}H_4Cl_4N_4O$ Formed by heating di chloro isatyde either with alcoholic potash or alone below 200° (E) Dirty violet powder

Di nitro-indin $C_{16}H_4(NO_2)_2N_4O_2$ Formed by boiling indin or hydrindin with HNO_3 (L) Bright violet powder, insol water, *v* sl sol alcohol and ether Forms a dark brown solution in $KOHAq$

Indin di-sulphonic acid $C_{16}H_4(SO_3H)_2N_4O_2$? Formed by oxidising hydrindin di-sulphonic acid with INO_3 , with K_2FeCy_6 , with $NaOCl$, or even by exposing it in alkaline solution to the air (G a A Schlieper, *A* 120, 24) Red deliquescent crystals, *v* sol water, sl sol alcohol, insol ether Its solution dyes silk and wool scarlet Ammonium sulphide reduces it to hydrindin di sulphonic acid It forms a purple solution in $KOHAq$, and on warming the solution it becomes pale red, probably through assimilation of water On adding HCl to the pale red solution a yellow pp is formed ($C_{16}H_{16}(SO_3H)_2N_4O_2$?), which, when heated, quickly changes to indin disulphonic acid Salts — K_2A 5aq lustrous red needles — Ag_2A bulky brown needles — BaA 2aq slender dark reddish-brown needles or crystals

VOL. III

powder M sol water, insol $BaCl_2Aq$, alcohol and cold $HClAq$

Hydrindin $C_{12}H_{12}N_4O_2$? Formed by the action of alcoholic potash upon indin, isatyde, thio isatyde, or di thio isatyde (Laurent *A Ch* [3] 3, 475) White, or pale yellow powder or needles (from alcohol), insol water, sl sol boiling alcohol Boiling HNO_3 converts it into a violet powder Hydrindin dissolves in warm aqueous KOH, and on cooling there separate pale yellow needles of a salt $C_{12}H_{12}KN_4O_2$ 3aq, which is decomposed by washing with water, leaving hydrindin

Hydrindin disulphonic acid, so called, $C_{12}H_8(SO_3H)_2N_4O_2$? Formed by the action of ammonium sulphide on indin sulphonic acid or on isatin sulphonic acid (G a A Schlieper, *A* 120, 20) Colourless radio crystalline mass, which becomes reddish when exposed to air *v* sol water, m sol alcohol, insol ether In alkaline solution it is oxidised by air to indin sulphonic acid — BaA 4aq white scales, *v* sol water, *v* sl sol $BaCl_2Aq$

Leucindin disulphonic acid $C_{16}H_{16}(SO_3H)_2N_4O_2$ Formed by boiling the preceding with baryta water (G a A Schlieper, *A* 120, 33) White crystalline mass, *v* sol water, sl sol alcohol Not reddened by the action of air on its alkaline solutions On evaporating with $HClAq$ there is formed indin disulphonic acid — BaA 5aq colourless crystals Its solution is not ppd by $AgNO_3$, till NH_4Aq is added

INDIPURPURIN is identical with *Indirubin*

v INDIGO

INDIRETIN *v* INDIGO

INDIRUBIN *v* INDIGO

INDIUM In At w 1134 Mol w unknown, as V D of element has not yet been determined [176°] (Winkler, *J pr* 102, 273)

S G $^{20^\circ}$ 7.11 to 7.147 (Reich a Richter, *J pr* 93, 480), $^{150^\circ}$ 7.362, $^{160^\circ}$ 7.421 (Winkler, *J pr* 95, 414, 102, 273) S H (0° to 100°) 0.5695 (Bunsen, *P* 141, 1) C E (0° to 100°) 0.000459 (Fizau, *C R* 68, 1125) Characteristic lines in emission spectrum 4510.2, 4101.3, 4071.6, 4032.7, 3852.8, 3834.7, 3257.8, 3255.5, 3038.7, 3008, 2982.3, 2940.8, 2889.8, 2559.5, 2527.1, 2351.3, 2306.9 (Hartley, *T* 1884, 102)

The observation of two indigo blue lines in the spark spectrum of a specimen of the *zinc-blende* of Freiberg in 1863, led Reich a Richter to the discovery of indium (*J pr* 89, 441, 90, 175, 92, 480)

Occurrence —In some *zinc blendes* from Freiberg (c 1 p c), also from Durham (Flight, *B* 10,

B

2054), and from Bohemia (Kachler, *J pr* 96, 447), in some Italian *galenas* (Denegri, *B* 11, 1249), in various zinc ores (Tanner, *J* 1874 1227), in the fumes from zinc-ovens (Böttger, *J pr* 98, 26), in some tungsten ores (Hoppe-Seyler, *A* 140, 247)

Preparation—Indium is more readily prepared from zinc which has been made from indium containing blends than from zinc-blende itself. The zinc is treated, for some days at the ordinary temperature, or for a shorter time at boiling temperature, with so much dilute H_2SO_4 or HClAq that a small quantity remains undissolved, the residue contains In, with some Zn, and Pb, Cu, Cd, As, and Fe. There are many methods for obtaining In from this residue, that of Bayer (*A* 168, 372) is simple, and yields very pure In. The residue is washed, treated with a few drops of dilute H_2SO_4 (to remove any basic Zn salts), again washed thoroughly with hot water, dissolved in HNO_3 (any SnO_2 which may be present is allowed to remain), evaporated with excess of H_2SO_4 until all HNO_3 is removed, and treated with water, the solution now contains sulphates of In and the other metals which may be present, but the greater part of the PbSO_4 remains insoluble. Large excess of NH_4Aq is added, whereby hydroxides of In and Fe are pptd with small quantities of hydroxides of Zn, Cd, Pb, and Cu, the ppt is well washed and dissolved in the smallest possible quantity of HClAq , the solution is boiled after addition of NaHSO_4 until the smell of SO_2 is almost gone, a basic sulphite of In, $2\text{In}_2\text{O}_3 \cdot 3\text{SO}_2$, is thus pptd as a fine crystalline powder. The ppt is free from salts of Cu, Zn, and Cd. If much Fe should have been present in the original Zn, small quantities of Fe salts may be pptd by the action of the air during filtration, in this case pptn should be conducted in CO_2 , or the ppt should be dissolved in NaHSO_4 and repptd by boiling. The ppt may contain Pb salts and traces of alkali, it is dissolved in SO_2 in which Pb sulphite is insoluble, after filtration In sulphite is pptd, free from Na salts, by boiling (cf Winkler, *J pr* 102, 278, Böttger, *J pr* 98, 26, R E Meyer, *A* 150, 137. For methods of preparing In from zinc-blendes v Reich a Richter, *J pr* 89, 441, 90, 175, 93, 480, Weselsky, *J pr* 94, 443, Richter, *J pr* 94, 414, Stolba, *D P J* 198, 223). The pptd basic In sulphite may be dissolved in H_2SO_4 after boiling off SO_2 , addition of NH_4Aq ppts $\text{In}_2\text{O}_3 \cdot \text{H}_2\text{O}$, which when strongly heated yields In_2O_3 . In is obtained from the oxide (1) by heating in a stream of pure H, (2) by mixing with pure C, and heating to a very high temperature, (3) by heating with an equal weight of Na cut in small slices, under a layer of fused NaCl in a porcelain crucible placed in a larger Hessian crucible, decomposing the alloy of Na and In so formed by water, and melting with Na_2CO_3 (Winkler, *J pr* 102, 275). Böttger (*J pr* 107, 89) recommends to ppt In from solutions in H_2SO_4 by placing a stick of pure Zn in the liquid, he washes the pptd metal with water, presses it with the finger, then between paper, and when quite dry fuses it under dry KCN.

Properties—A silver white, lustrous, ductile metal; softer than lead, leaves a mark when

rubbed on paper. Non-crystalline. Electro-negative \sim Zn and Cd; much less volatile than these metals. Unchanged in air at ordinary temperature, but burns to In_2O_3 with blue-violet flame and brownish fumes, when strongly heated in air. Combines directly with Cl, Br, I, and S when heated. Boiling water is not decomposed by In. Soluble in dilute acids with evolution of H and formation of salts In_2X_2 , where $\text{X} = \text{SO}_4, 2\text{NO}_3$, &c.

The at w of In has been determined (1) by synthesis of In_2O_3 from an (Ruch a Richter, *J pr* 92, 484, Winkler, *J pr* 94, 8, 102, 282, Bunsen, *P* 141, 28), (2) by analyses of In_2S_3 (R a R, *lc*) (3) by decomposing NaAuCl_4 by In, and determining the Au (Winkler, *J pr* 102, 212), (4) by determining the VD of InCl_3 , InCl , and InCl (Nilson a Pettersson, *C J* 53, 814), (5) by determining the SH of In (Bunsen, *P* 141, 1).

The atom of In appears to be monovalent (in InCl), divalent (in InCl_2), and trivalent (in InCl_3), in gaseous molecules, as the lower chlorides are decomposed by water with formation of In and InCl , it is probable that in solutions of its haloid compounds the atom of In is directly combined with at least three monovalent atoms.

In is distinctly metallic, with acids it evolves H and forms salts. A few basic, and some double, salts are known. In forms an ammonia alum $\text{InO}_3 \cdot \text{H}_2\text{O}$, reacts towards acids as a salt forming hydroxide. In is closely related to Al and Ga, less closely to Tl, it is also related to the other earth metals Sc, Yt, La, and Yb (v EARTH, METALS OF THE, vol 11 p 424). The investigation of In compounds is as yet far from complete.

Detection and Estimation—In salts colour the flame blue violet. Hoppe-Seyler (*A* 140, 247) boils c 1 gram of an In ore with *aqua regia*, neutralises by soda, filters, adds Na acetate, and ppts by H_2S , he dissolves the ppt in acid, and repts, the In_2S_3 is then tested in the flame after moistening with HClAq . The spectral lines 4510.2 and 4101.3 are very characteristic. Boiling with NaHSO_4 causes pptn of r, fine crystalline ppt $2\text{In}_2\text{O}_3 \cdot 3\text{SO}_2 \cdot 8\text{H}_2\text{O}$, this salt is used for the estimation of In.

Indium bromide InBr . White crystalline tablets, v sol water, formed by heating In in a stream of CO , charged with Br, and subliming (R Meyer, *A* 150, 429). VD not determined.

Indium chlorides. In combines with Cl in three proportions, forming InCl , InCl_2 , and InCl_3 .

INDIUM MONOCHLORIDE InCl . Mol w 148.77. VD at c $1100^\circ\text{--}1400^\circ = 78.16$ (Nilson a Pettersson, *C J* 53, 821). Obtained as a reddish black, vitreous, radiated, crystalline mass, by distilling InCl_3 (q v) on to In (rather more than the calculated quantity), heating for a little in a sealed tube, and distilling in a stream of CO , (N a P, *lc*). When melted InCl forms a dark-red liquid, in thick layers appearing almost black. Deliquescent, gradually decomposes in moist air, and quickly in water, to In and InCl_2 .

INDIUM DICHLORIDE InCl_2 . Mol w 184.14. VD at $1000^\circ\text{--}1400^\circ = 99.62$ (Nilson a Pettersson, *C J* 53, 820). White radiated crystals, obtained by heating In to its melting point in a current of dry HCl free from air until an amber-

coloured liquid is obtained, and removing any adhering HCl by heating in dry at free CO_2 . Unchanged in dry air, but deliquesces in ordinary air. Decomposed by water to form $\text{InCl}_3 \cdot \text{Aq}$ (N & P, *lc*)

INDIUM TRICHLORIDE InCl_3 . Mol wt 219.51 V D at c $8.7^\circ = 106.9$ (Nilson & Pettersson, *C J* 53, 818), at bright red heat V D = 113.88 (V & C Meyer, *B* 2, 611). InCl_3 does not appreciably volatilise at 140° , at c 600° volatilisation is slow and V D is rather higher than that calculated for InCl_3 , the normal V D is attained between 600° and 850° , at temperatures towards 1000° dissociation begins, probably into Cl and InCl , or InCl (N & P, *lc*). InCl_3 is prepared by heating In or a mixture of In_2O_3 with C, in a stream of dry Cl. Nilson & Pettersson heated molten In in dry air free HCl, and then gently heated the InCl_3 thus formed in air free, dry, Cl, and finally distilled in a current of dry, air free, CO_2 . White, lustrous tablets, deliquescent, sol in water with production of heat, the solution may be evaporated on a steam bath almost unchanged, but at higher temperatures decomposition occurs, probably with production of oxychlorides.

InCl_3 combines with KCl, NaCl, LaCl, and PtCl_4 to form crystalline double salts (R Meyer, *A* 150, 144, Nilson, *B* 9, 1059). The compound $2\text{InCl}_3 \cdot 6\text{KCl} \cdot 3\text{H}_2\text{O}$ separates in quadratic crystals from a solution of the mixed salts in proper proportions on evaporation.

Indium cyanide vol in p 332

Indium hydrosulphide The white pp produced by adding NH_4 sulphide, or H_2S , to solution of an In salt, after addition of tartaric acid and NH_4Aq , is probably a hydrosulphide, when dried, H_2S is evolved and In_2S_3 remains (R Meyer, *A* 150, 429).

Indium hydroxide v *Indium oxides and hydroxide*

Indium iodide InI_3 V D not determined. Yellow, crystalline, very hygroscopic, may be distilled in dry CO_2 , easily melted to a dark reddish brown liquid. Prepared by heating In in I vapour (R Meyer, *A* 150, 144, 429).

Indium oxides and hydroxide In forms two oxides, InO and In_2O_3 , the V D of neither has been determined, the existence of intermediate oxides is probable. In_2O_3 forms at least one hydrate $\text{In}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$. The oxides are basic, only salts corresponding to In_2O_3 have been isolated, although the lower oxide is said to dissolve in dilute acids without decomposition into In and In_2O_3 .

Indium monoxide InO Mol w unknown, as the oxide has not been volatilised. Obtained by heating In_2O_3 in H at c 300° until the oxide becomes almost black and water is no longer evolved. Forms a light, loose, powder, which quickly oxidises to yellow In_2O_3 , if brought into air before it is quite cold. Very pyrophoric. InO is changed by conc HNO_3 to In_2O_3 , with evolution of NO , dilute acids dissolve it slowly without apparent formation of In_2O_3 or In (Winkler, *J pr* 94, 1, 95, 414, 98, 344, 102, 273).

Indium sesquioxide In_2O_3 . Mol. w unknown as the oxide has not been volatilised. SG 7.179, SH $(0^\circ-100^\circ)$ 0.807 (Nilson & Pettersson, *B* 18, 1459). Obtained by ppg solution of an In salt by NH_4Aq , washing and heat-

ing the pp, or by heating In to full redness in air, also by strongly heating In carbonate or nitrate. A yellow powder, becomes brown on heating but yellow again when cold. (It is doubtful whether pure In_2O_3 is yellowish or white.) Very infusible, reduced to metal by heating with C, or in H, or with Na, reduction in H begins at c $190^\circ-200^\circ$, and at c 300° InO is formed (v *supra*). Soluble, in acids, quickly on heating, forming salts In_2X ($\text{X}=\text{SO}_4, 2\text{NO}_3$, &c).

Oxides intermediate between InO and In_2O_3 , possibly exist. By heating In_2O_3 in H to c 200° , a greyish blue body is obtained probably In_2O_3 , at c 230° a green substance, probably In_2O_3 , remains (Winkler, *lc*).

Indium hydroxide $\text{In}_2\text{O}_3 \cdot \text{H}_2\text{O}$ or $\text{In}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ Formed by ppg a solution of an In salt by NH_4Aq , washing the pp and drying at 100° . The pp by NH_4Aq is gelatinous and resembles AlO_2H_3 , in air it dries to horny semitransparent lumps. Insol in NH_4Aq , easily sol in KOH or NaOH or NaOHAq , dissolves in acids to form salts In_2X ($\text{X}=\text{SO}_4, 2\text{NO}_3$, &c). A series of very unstable hydrates of In_2O_3 probably exists (cf Carnelley & Walker, *C J* 53, 88).

Indium oxybromide The white amorphous solid formed by heating In_2O_3 in Br vapour is probably an oxybromide, this substance is said not to be decomposed by heating with acids or alkalis (R Meyer, *A* 150, 137).

Indium oxychloride When $\text{InCl}_3 \cdot \text{Aq}$ is boiled down to dryness, the white residue is probably an oxychloride.

Indium salts Not many salts of In have been isolated and examined. They are obtained by dissolving In or In_2O_3 in acids, and evaporating, and in some cases by ppn from other In salts in solution. The chief salts are the carbonate, nitrate, sulphate, and a basic sulphite (v *Carbonates*, *Nitrates*, &c). The sulphate forms an ammonia alum, $\text{In}_2(\text{SO}_4)_3 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 24\text{H}_2\text{O}$, but with K_2SO_4 and Na_2SO_4 it forms double sulphates $\text{In}_2(\text{SO}_4)_3 \cdot \text{K}_2(\text{Na})\text{SO}_4 \cdot 8\text{H}_2\text{O}$.

Indium sulphide In_2S_3 Mol w unknown as compound has not been gasified. Obtained by ppg a neutral or feebly acid solution of an In salt by H_2S , and drying the pp, also by heating together In and S, or In_2O_3 and S. A yellowish-grey solid. If In_2O_3 is heated with S and Na_2CO_3 , and the fused mass is treated with water, In_2S_3 remains as lustrous tablets resembling mosaic gold (Winkler, *lc*). In_2S_3 is infusible, with acids it gives In salts and H_2S (Reich & Richter, *lc*). Heated in air it is burnt to In_2O_3 . According to Winsinger (*Bl* (2) 49, 452) In_2S_3 is obtained in aqueous solution in a colloidal form, by passing H_2S into In_2O_3 suspended in water, the dark yellow liquid thus obtained can be freed from H_2S by boiling, it is coagulated by acetic acid and also by salts. For reactions of alkali sulphides with In salts v R Meyer, *lc*.

Potassium, and sodium, indium sulphides, $\text{K}_2\text{In}_2\text{S}_3$, $\text{Na}_2\text{In}_2\text{S}_3$. Formed by fusing together 1 pt In_2O_3 , 6 pts S , and 6 pts K_2CO_3 or Na_2CO_3 . The K salt remains as hyacinth red quadratic tablets on lixiviating the fused mass with water, the Na salt goes into solution and separates on standing as $\text{Na}_2\text{In}_2\text{S}_3 \cdot \text{H}_2\text{O}$ which on drying gives $\text{Na}_2\text{In}_2\text{S}_3$ (R. Schneider, *J pr* [2] 9, 209).

(β)-Indogenide of ψ isatin is INDIGO

Indogenide of ethyl ψ isatin is *Ethyl indirubin* v INDIGO

INDOGENIDE OF p-NITRO-BENZALDEHYDE $C_{13}H_{10}N_2O_3$ &

$C_8H_7<\frac{CO}{NH}>CCH_2C_6H_4(NO_2)$ *p Nitro-benzylidene-ψ-indoxyl* [273°] Formed by adding an acetic acid solution of *p* nitro benzaldehyde to an aqueous solution of indoxyl acidified with HCl Red needles (Baeyer, *B* 16, 2199)

INDOGENIDE OF PYRUVIC ACID $C_{11}H_8NO_4$

& $C_8H_7<\frac{CO}{NH}>CMeCO_2H$ [197°] Prepared by adding HCl to an aqueous solution of indoxyl and pyruvic acid (Baeyer, *B* 16, 2199) Red needles Easily soluble in alcohol and acetone Dissolves with a red colour in alkalis, with a blue colour in conc H_2SO_4

INDOGENE & INDIGO**INDOLE** C_8H_7N & $C_8H_7<\frac{CH}{NH}>CH$ *Ketole*

Mol w 117 [52°] (251°) (Ciamician & Zatti, *B* 22, 1980) VD 4.45 (calc 4.05) Occurs in small quantity in human excrement (Briegleb, *J pr* [2] 17, 133)

Formation — 1 By passing the vapour of oxindole over heated zinc dust (Baeyer, *A* 140, 295, *Suppl* 7, 56, Engler & Jancke, *B* 9, 1411) — 2 By distilling with zinc dust the yellow product of the action of tin and HCl on indigo (B) — 3 By fusing *o* nitro cinnamic acid with KOH and iron filings (Baeyer & Lummerling, *B* 2, 679, *Z* [2] 6, 213, Beilstein & Kuhlberg, *A* 163, 141) — 4 Formed to the extent of 5 p c in the passage through a red hot tube of diethyl-*o*-toluidine, in less quantity from di methyl-*o*-toluidine, in small quantity from methyl ethyl aniline, ethyl acetanilide, and di ethyl aniline, and in trace only from ethyl aniline when subjected to like treatment (Baeyer & Caro, *B* 10, 692, 1262) — 5 By digesting albumen with pancreas and water at 40° to 45° for several days (Nencki, *B* 8, 336, Kühne, *B* 8, 206) According to Harris and Tooth (*J Physiol* 9, 220) its formation is due to a special micro-organism — 6 By distilling albumen (1 pt) with KOH (8 pts), the yield being about 25 p c (Engler & Jancke, *B* 9, 1411, Nencki, *J pr* [2] 17, 98) — 7 By distilling (3,4,1) nitro propenylbenzoic acid with lime (Widmann, *B* 15, 2552) — 8 By boiling aniline with di chloro acetic aldehyde or with di chloro di ethyl oxide (Berlinerblau, *M* 8, 180) — 9 By heating *o* chloro-*o*-amido styrene with NaOEt at 165° (Lipp, *B* 17, 8067) — 10 Together with ethane, ethylene, and propylene, by the distillation of *o* cumidine

$C_8H_7(NH_2)(C_6H_5)$ over red hot PbO (Fileti, *G*, 13, 381) — 1 By the dry distillation of *o* tolyloxamic acid (Mauthner & Suida, *M* 7, 238) — 12 From phenyl-ethylene diamines by successive oxidation with CrO_3 and distillation over zinc dust (Prud'homme, *Bl* [2] 28, 55c) — 13 By fusing carbosyryl with potash (Morgan, *C N*, 36, 239) — 14 In small quantity, by heating the phenyl hydrazide of pyruvic acid with $ZnCl_2$ at 200° (E Fischer, *B* 19, 156°) — 15 By distilling calcium phenyl amido acetate with calcium formate (Mauthner & Suida, *M* 10, 253)

Preparation — 1 By heating aniline (50g) with an equal volume of water with inverted condenser and gradually adding di chloro ether (25g) After boiling for an hour the excess of aniline is distilled off, the residue heated for 5 hours at 220° (Berlinerblau, *M* 8, 18°) — 2 By distilling a mixture of calcium phenyl amido acetate with calcium formate, extract the distillate with ether, shaking the ether with dilute acid to remove aniline, evaporating and distilling with steam The indole is purified by conversion into the picrate The yield is 5 p c of the theoretical quantity (M & S)

Properties — Colourless laminae, m sol not water, v sol alcohol, ether, and ligroin Readily volatile with steam An alcoholic solution, acidified by HCl, dyes pine wood yellow Has a peculiar, but not very powerful, odour It is a very weak base, with conc $HClAq$ it forms a sparingly soluble salt, decomposed by boiling water

Reactions — 1 Suspended in water and subjected to the action of ozonised oxygen indole is converted into indigo and resinous products (Nencki, *B* 8, 727, 1517) Indigo appears in the urine after subcutaneous injection of indole — 2 Aqueous CrO_3 yields a bulky violet brown pp, insol ether, chloroform, and benzene, sl sol alcohol, forming a red solution sol conc $HClAq$ (L & J) — 3 Heated with MeI it gives di methyl quinoline dihydride (Ciamician & Zatti, *B* 22, 1980) — 4 When to an aqueous solution of indole there is added a few cc of $HClAq$, and then a large quantity of fuming HNO_3 (previously partially freed from nitrous fumes by evaporation), a red pp is formed which may be purified by solution in alcohol and precipitation by adding ether This substance, so called nitroso indole nitrate $C_{10}H_{13}(NO)_2HNO_3$, forms minute red needles, v sl sol water and ether, v sol alcohol nearly insol dilute nitric acid It detonates sharply when heated Alcoholic ammonium sulphide reduces nitroso indole nitrate to so called hydrazo indole $C_{10}H_{13}N_2$ (?), which forms yellow needles, sol alcohol and ether, melting at 140° to a deep-blue mass Acids and alkalis convert it into a dark brown colouring matter termed azo indole by Nencki

Picrate $C_{12}H_9N_3O_7$ Long red glittering needles

Acetyl derivative $C_{10}H_9Nac$ [183°] From indole and Ac_2O at 190° (Baeyer, *B* 12, 1314) Long needles (from water) or four sided pyramids (by sublimation)

(β)-Acetyl-indole $C_{10}H_7<\frac{C CO CH_3}{NH}>CH$ *Methyl indol ketone* [190° or] Obtained by heating

indole (a)-carboxylic acid, prepared from methylketole, with ten times its bulk of Ac_2O for 7 hours at 220° (Carlo Zatti, *Rend. Accad. Linc.* [4] 4, 184, B 22, 662) White needles Sublimes in colourless plates, sl sol cold, v sol warm water and benzene, may be extracted from its aqueous solution by ether Gives indole when heated with conc HClAq It readily yields an oxim and an oily phenyl hydrazide Potash fusion converts it into indole (β) carboxylic acid [214°] identical with that obtained by oxidising skatole

Picrate [183] Needles, sl sol cold benzene

Oxim $\text{C}_8\text{H}_7\text{C}(\text{NOH})\text{Me}$ [144° - 147°] White needles

Di-acetyl indole $\text{C}_8\text{H}_5\text{C}(\text{COCH}_3)_2$ [147° - 150°]

Prepared by heating indole (a)-carboxylic acid with Ac_2O and separated from the preceding by its greater solubility in water containing Na_2CO_3 and in boiling benzene (Zatti) Needles (by sublimation), sl sol boiling water When boiled with aqueous KOH or K_2CO_3 , it yields (β) acetyl indole

References - Di chloro indole, Benzyl indole, Methyl indole, Methyl ethyl indole, Ethyl indole

Retin indole $\text{C}_8\text{H}_7\text{NO}$? Obtained by treating di chloro indole (chloro oxindole chloride) with HI dissolved in HOAc passing in SO and ppk with NaOH (Bayer, B 12, 1413) Amorphous, insol NaOHAq , v sol alcohol and ether Not volatile with steam Its solution in HOAc mixed with HCl colours pine wood red On dry distillation it yields indole

INDOLE (a) CARBOXYLIC ACID $\text{C}_8\text{H}_7\text{NO}_2$

$\text{C}_8\text{H}_5\text{C}(\text{COOH})_2$ [201°]

Formation -1 By heating the phenyl hydrazide of pyruvic ether with ZnCl_2 at 195° (E Fischer, B 19, 1567, A 236, 140) -2 By fusing (a) methyl indole (methyl ketole) (1 pt) with KOH (15 pts), the acid being prepd by H_2SO_4 from the dissolved product, the yield is over 50 p.c (Ciamician & Zatti, *Rend. Accad. Linc.* [4] 4, 746) -3 From acetyl (a) methyl indole $\text{C}_8\text{H}_5\text{C}(\text{NMe})\text{COCH}_3$ by potash fusion (Ciamician & Magnanini, B 21, 673)

Properties - Needles (from water) M sol hot water and benzene, v sol alcohol and ether May be sublimed in plates, but suffers partial decomposition thereby At 230° it splits up into indole and CO_2 Pine wood acidified with HCl is not coloured yellow by it. With isatin and H_2SO_4 it gives a reddish violet colouration It forms a pyruic acid compound crystallising in slender golden needles Its Ba salt is soluble Ac_2O at 220° forms (β) acetyl indole and di acetyl-indole

Anhydride $\text{C}_{10}\text{H}_7\text{N}_2\text{O}_3$

$\text{C}_8\text{H}_5\text{C}(\text{CH}_3\text{COON})_2$ [312° - 315°] Mel

w Confirmed by Raoult's method (Magnanini, B 23, 2508) Formed by boiling the acid with

Ac_2O using an inverted condenser. Yellow needles

Methyl ether MeA' [152°] Needles

Indole (B)-carboxylic acid

$\text{C}_8\text{H}_5\text{C}(\text{COOH})_2$ [214°] Formed by fusing (β) methyl indole (skatole) with KOH (Ciamician, Magnanini & Zatti, B 21, 673, 1929) Obtained also by fusing (β) acetyl indole with caustic potash (Zatti, B 22, 664) Plates (from water), decomposed on fusion Sl sol benzene and boiling water, m sol alcohol and ether, almost insol ligroin Its aqueous solution evolves CO_2 on boiling With isatin and H_2SO_4 it gives a brownish violet colour Its ammonium salt gives pps with CuSO_4 and with FeCl_3 . It does not yield a picric acid compound.

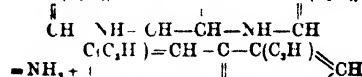

Indole di carboxylic acid

$\text{C}_{10}\text{H}_7\text{C}(\text{COOH})_2$ [above 250°] Obtained by saponifying its acid ether, which is formed when $\text{CO Et C}_8\text{H}_5\text{N}_2\text{H CMe CO Et}$, the product of the condensation of hydrazido benzene ether with pyruvic ether, is heated with zinc dust (Roder, A 236, 169) Slender needles, sol hot alcohol and acetic acid, sl sol ether and water Does not colour pine wood Decomposed on fusion giving off CO_2 and yielding a product that behaves like indole towards pine wood.

Mono ethyl ether EtHA' [250°] Yellow needles (from HOAc)

INDOLES Alkylated derivatives of indole may be formed synthetically in the following ways

(a) By removal of NH_2 from the phenyl hydrazides of ketones, aldehydes, or ketonic acids Thus with the phenyl hydrazide of acetone $\text{C}_8\text{H}_5\text{N}_2\text{H CMe} = \text{NH}_2 + \text{C}_8\text{H}_5\text{C}(\text{CH}_3)_2$, and in like manner from the phenyl methyl hydrazide of pyruvic acid $\text{C}_8\text{H}_5\text{N}_2\text{H Me CMe CO}_2\text{H} = \text{NH}_2 + \text{C}_8\text{H}_5\text{C}(\text{CH}_3)_2\text{CO}_2\text{H}$ (E Fischer, A 236, 116) (b) By elimination of NH_2 from alkylated di pyrroles -

(Dennstedt, B 21, 3429) (c) By heating (β) bromo β acetyl propionic acid with aromatic amines (Wolff, B 21, 3360) Thus o- or p-toluidine gives tri methyl indole, (β) naphthylamine gives di methyl (β) naphthindole, while ethyl aniline forms di methyl ethyl-indole.

Indoles may be converted by alkyl iodides into derivatives of quinoline dihydride

INDOLINE v Indigo

INDONAPHTHENE

The hypothetical hydrocarbon C_{10}H_7 or $\text{C}_8\text{H}_5\text{C}(\text{CH}_3)_2$ which stands in the same relation to indole that naphthalene stands to quinoline (Baeyer & Perkin, jun, B 17, 122) The name *indene* has also been proposed for

thesame hydrocarbon (Roser, *A* 247, 132), v also METHYL INDONAPHTHENE Besides the methods mentioned below, indonaphthene derivatives may be formed by condensation of naphthalene de

riative Thus $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CHCl \end{smallmatrix} \begin{smallmatrix} CO \\ \diagdown CCl_2 \end{smallmatrix}$, a product of

the chlorination of (β)-naphthoquinone is converted by cold aqueous NaOH into

$C_6H_4 \begin{smallmatrix} \diagup C(OH)CO_2H \\ \diagdown CHCl \end{smallmatrix} \begin{smallmatrix} CO_2H \\ \diagdown CCl_2 \end{smallmatrix}$ (Zincke, *B* 20, 2894) which

may be oxidised by chromic acid to

$C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CHCl \end{smallmatrix} \begin{smallmatrix} CO \\ \diagdown CCl_2 \end{smallmatrix}$ [59°]

INDONAPHTHENE DIHYDRIDE CARBOXYLIC ACID $C_{16}H_{16}O_4$, ϵ

$C_6H_4 \begin{smallmatrix} \diagup CH_2 \\ \diagdown CH_2 \end{smallmatrix} CH CO_2H$ *Hydrindonaphthene carboxylic acid* [130°] *S* 833 at 100°

Formation—1 By heating the corresponding di carboxylic acid until the evolution of CO_2 has ceased, and distilling the product (Baeyer a Perkin, *jun*, *B* 17, 122)—2 By the action of (1 mol of) ω -di bromo xylene (o xylenebromide) upon aceto acetic ether (1 mol) and NaOEt (2 mols) and saponification of the product with alcoholic KOH (Scherks, *B* 18, 378)

Properties—Colourless needles (from water), may be distilled when quickly heated. Sl sol cold water. On oxidation with $KMnO_4$, it yields phenyl-glyoxylic acid. It forms a bulky white silver salt, sl sol hot water.

Indonaphthene dihydride dicarboxylic acid

$C_6H_4 \begin{smallmatrix} \diagup CH_2 \\ \diagdown CH_2 \end{smallmatrix} C(CO_2H)_2$, [199°] Formed by the action of di ω bromo o xylene on malonic ether (1 mol) and NaOEt (2 mols) in ether (Baeyer a Perkin, *jun*, *B* 17, 122, Perkin, *jun*, *C* 1 53, 7), the resulting ether being saponified. Trimetric plates, m sol hot water, alcohol, and ether, sl sol cold water. When heated above 200° it gives off CO_2 and leaves the mono carboxylic acid— Ag_2A'' white amorphous pp becoming crystalline, sl sol water.

INDONAPHTHOQUINONE $C_{16}H_8O_2$, ϵ

$C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CH_2$, [131°] *Di keto indonaphthene* *Di keto hydrindene* Formed by warming its carboxylic ether $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CH CO_2Et$ with alkalis (Wislicenus, *A* 246, 351). Best obtained by acidifying an aqueous solution of the sodium derivative $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CNa CO_2Et$, extracting with ether, and leaving the ethereal solution to stand, when CO_2 is given off.

Properties—Small needles (from benzene ligroin), v sol hot alcohol and benzene, m sol ether and hot ligroin, v sl sol cold ligroin and water. Dissolves in alkalis with intense yellow colour.

Reactions—1 Gives a phenyl hydrazide

$C_6H_4 \begin{smallmatrix} \diagup C(N.HPh) \\ \diagdown CO \end{smallmatrix} CH_2$, [163°] crystallising in yellow needles, insol water and ligroin, v e sol ether and benzene. With phenyl hydrazide at 100° it gives rise to a di phenyl hydrazide

$C_6H_4 \begin{smallmatrix} \diagup C(N.HPh) \\ \diagdown C(N.HPh) \end{smallmatrix} CH_2$, which forms flesh-coloured plates [171°], and when dissolved in H_2SO_4 , is coloured deep bluish green by $FeCl_3$ (W

Wislicenus a Kötze, 252, 73)—2 Forms a nitroso erivative $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CNOH$

[198°] crystallising from HOAc in triangular plates—3 *Benzoic aldehyde* at 120° forms $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CCHPh$ [160°]—4 Gives with

bromine a compound $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CC \end{smallmatrix} CBr_2$, [177°] crystallising in plates, m sol hot alcohol and HOAc, v sol ether and CS_2 (cf Zincke, *B* 20, 3216). This di bromo derivative, which is also formed by the action of bromine on $C_6H_4 \begin{smallmatrix} \diagup CC \\ \diagdown C(NH) \end{smallmatrix} CBr$ and on

$C_6H_4 \begin{smallmatrix} \diagup CO - C(NH_2) \\ \diagdown C(NH) \end{smallmatrix} CH$, is converted by the action of alkali into bromoform, phthalic acid, and the compound $C_6H_4 \begin{smallmatrix} \diagup C(OH) \\ \diagdown CO \end{smallmatrix} CBr$ [118°], whence

Br forms again the original $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CBr_2$,

while Cl forms $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CClBr$ [147°] (Zincke, *B* 21, 2394). The corresponding $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CCl_2$ [125°] is formed by the action

of chlorine on $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CCl_2 \end{smallmatrix} \begin{smallmatrix} CO \\ \diagdown CCl_2 \end{smallmatrix}$ dissolved in aqueous Na_2CO_3 .

Indonaphthoquinone carboxylic ether

$C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CH CO_2Et$ [78°] Formed by the action of NaOEt (2 mols) on phthalic ether (1 mol) and subsequent treatment with acetic ether, the product $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CNa CO_2Et$ being treated with dilute H_2SO_4 (Wislicenus, *A* 246, 349). Slender yellow needles, insol water, v e sol alcohol, ether, benzene, and ligroin. $FeCl_3$ colours its alcoholic solution deep red. Dissolves in aqueous Na_2CO_3 , expelling CO . If its alkaline solution be boiled and then acidified CO_2 is evolved and indonaphthoquinone liberated. It forms a phenyl hydrazide. If its acid solution is boiled with water there is formed $C_{16}H_{16}O_4$, which dyes wool violet red and forms crystalline $C_{16}H_{16}BrO_4$ [196°] and $C_{16}H_{16}Br_2O_4$ [242°].

Salts— $C_{16}H_8O_2Na$ aq yellow needles (from water). Gives with MeI the compound $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} CMe CO_2Et$, crystallising in prisms [74°], v e sol alcohol and ether, insol water, sol NaOHAq with rose colour— $(C_{16}H_8O_2)_2Cu$ green crystals (from alcohol).

INDONE The ketone $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown CH \end{smallmatrix} CH$, a number of the haloid derivatives C^* which have been described by Roser (*A* 247, 132). Indone may also be viewed as the anhydride of di oxy INDONAPHTHENE.

INDOPHANE $C_{22}H_{14}N_2O_4$. A blue substance, resembling indigo, produced, together with naphthyl purpuric acid, by adding a hot concentrated solution of KCy (45 g) to 1 nitro naphthol (? g) dissolved in boiling water (2 litres) to which just enough NH_3 has been added to effect

solution (Hlasiwetz, Sommaruga, *C C* 1871, 617) Violet mass with green lustre, insol. water, alcohol, ether, benzene, and C_{12} , m sol H_2SO_4 , and hot $HOAc$, forming purple solutions. May be sublimed. Nitric acid converts it into a brownish red body, soluble in alkalis. Ferrous sulphate mixed with lime reduces it. Aqueous KOH forms $C_{12}H_7KN_2O_4$, a body greatly resembling indigo, NaOH acts in like manner.

INDOPHENAN ($C_{11}H_7NOS$)₂. Formed by shaking isatin (1 pt.) with H_2SO_4 and benzene that contains thiophene $C_4H_5NO_2 + C_6H_5S = H_2O + C_{12}H_7NOS$ (Baeyer, *B* 12, 1309, 16, 2188, 18, 2637, V Meyer, *B* 15, 2893, 16, 1465, P Meyer, *B* 16, 2269, Gumpert, *J pr* [2] 32, 278) Blue powder, which exhibits a coppery lustre when rubbed, or small needles (from alcohol phenol). Insol water, benzene, and ligroin, v sl sol alcohol, ether, and CS_2 , sl sol $HOAc$. In H_2SO_4 it forms a blue solution, whence it is pptd by water. Cannot be sublimed. May be reduced by zinc dust and $HOAc$ to a colourless body which is re oxidised to indophenin on exposure to air. Bromo-, di bromo-, and methyl indophenins may be formed in like manner by using bromo-, di bromo-, or methyl isatin in place of isatin in the above preparation.

INDOPHENOLS Quinonimides of the formula $C_6H_4 \begin{smallmatrix} \diagup NH \\ \diagdown NR' \end{smallmatrix}$, where R' is an aromatic radicle containing hydroxyl (*c/* INDIMINES). Thus when a mixture of di methyl *p* phenylene diamine and (a) naphthol is oxidised with NaOCl or $K_2Cr_2O_7$ there is formed the dark blue indophenol

$C_6H_4 \begin{smallmatrix} \diagup NMe_2Cl \\ \diagdown C_{10}H_7OH \end{smallmatrix}$ (Pabst, *Bl* [2] 38, 161),

while *p* amido phenyl piperidine mixed with phenol and oxidised by K_2FeC_4 forms a similar

body $C_6H_4 \begin{smallmatrix} \diagup N C_6H_5Cl \\ \diagdown N C_6H_5OH \end{smallmatrix}$ (Leilmann & Geller, *B* 21, 2288).

INDOANTHIC ETHER $C_{11}H_{11}NO$, *ie.* $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown NH \end{smallmatrix} > C(OH)CO_2Et$ [107] Prepared

by the careful oxidation of indoxylic ether with $1c.Cl_2$ (Baeyer, *B* 15, 775) Yellow needles or monoclinic prisms. Sol water and ether. On further oxidation it gives $CO_2H C_6H_4 NH CO CO_2Et$. On reduction it is reconverted into indoxylic ether. Decomposed by alkalis with formation of anthranilic acid.

Nitrosamine $C_6H_4(NO)NO$, [113°] Light yellow needles or tables. Sol alcohol and ether, sl sol water.

INDOXYL C_6H_7NO *ie.* $C_6H_4 \begin{smallmatrix} \diagup C(OH) \\ \diagdown NH \end{smallmatrix} > CH$ (stable form) or $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown NH \end{smallmatrix} > CH_2$ (transition form).

Formation—1 By warming potassium indoxyl sulphate with HCl or H_2SO_4 .—2 By heating indoxylic acid alone or with H_2SO_4 (Baeyer, *B* 14, 1744).—3 By boiling *o* nitro phenyl acetylene with acid ammonium sulphite, and treating the product with zinc dust and ammonia (Baeyer, *B* 15, 56).—4 By reducing isatogen-sulphurous acid with zinc dust and ammonia.

Properties—Oil. Not volatile with steam.

In the pseudo form $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown NH \end{smallmatrix} > CH_2$ it is not known in the free state, but di substitution products of ψ indoxyl are stable. Nevertheless in doxyl forms condensation products, called indogenides, with bodies containing a CO group, in which reactions it must be supposed first to change into the pseudo form.

Reactions—1 In alkaline solution it is rapidly oxidised in the air to indigo. $FeCl_3$ forms a white amorphous body, which is immediately converted by HCl into indigo (E. Baumann & Tiemann, *B* 13, 415).—2 Indoxyl is not affected by H_2SO_4 , or conc $HClAq$, but dilute $HClAq$ converts it into an amorphous red substance.—3 A solution in H_2SO_4 , treated with *o* nitro-phenyl propionic acid gives indoin.—4 On warming with a solution of Na_2CO_3 and *o* nitro-phenyl propionic acid, indigo is produced.—5 By the action of Na_2CO_3 upon an alcoholic solution of isatin and indoxyl there is formed indirubin, while with bromo isatin the product is bromo indirubin (Baeyer).—6 Bromine gives tri bromo aniline (E. Baumann & Tiemann, *B* 12, 1192).—7 In alkaline solution $K_2S_2O_8$ forms indoxyl sulphuric acid.—8 Diazo benzene chloride forms $C_6H_4 \begin{smallmatrix} \diagup C(OH) \\ \diagdown N_2Ph \end{smallmatrix} > CH$ [236°] (Baeyer, *B* 16, 2190).

Nitrosamine $C_6H_4 \begin{smallmatrix} \diagup C(OH) \\ \diagdown N(NO) \end{smallmatrix} > CH$ Formed

by the action of nitrous acid on indoxyl (Baeyer, *B* 16, 2188). Slender yellowish needles. When boiled with HCl it gives indigo.

Isonitroso derivative of ψ indoxyl

$C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown NH \end{smallmatrix} > CNOH$ See oxim of ψ ISATIN.

Ethyl derivative $C_6H_4 \begin{smallmatrix} \diagup C(OEt) \\ \diagdown NH \end{smallmatrix} > CH$.

Formed by heating the ethyl derivative of indoxylic acid. Oil, volatile with steam. Smells like indole, and colours pine wood, acidified with HCl, brownish red. Its picric acid compound $C_{10}H_{11}NOC_6H_2(NO_2)_3OH$ forms brown needles. Its nitroso derivative

$C_6H_4 \begin{smallmatrix} \diagup C(OH) \\ \diagdown N(O) \end{smallmatrix} > CH$ forms yellow prisms [85°], sol alcohol, insol water, and converted into indigo by heating with HCl (Baeyer, *B* 15, 781).

Indoxyl sulphuric acid $C_6H_7NSO_4$. Occurs in the urine of herbivora and, in smaller quantity, in that of man (Schunck, *P M* [4] 14, 288, Hoppe Seyler, *C C* 1864, 511, H 8, 79, E. Baumann & Tiemann, *B* 13, 408). When indole is introduced into a dog by injection or in food large quantities of indoxyl sulphuric acid appear in the urine (Jaffé, *Fr* 11, 358, E. Baumann & Brieger, *H* 3, 254). Indoxyl sulphuric acid is also formed by adding $K_2S_2O_8$ to a solution of indoxyl in aqueous KOH (Baeyer, *B* 14, 1745).

Potassium salt—KA'. Plates (from hot alcohol). V sol water, v sl. sol cold alcohol. Not affected by KOH even at 170°. Decomposed by hot dilute HCl or H_2SO_4 , or even by water at 120°, into indoxyl and H^+SO_4 . When warmed with $FeCl_3$ and a little HCl it is entirely converted into indigo. Indigo is also formed when the salt is heated alone.

INDOXYLIC ACID C_8H_7NO , $\epsilon\epsilon$

$$C_8H_7\langle\begin{smallmatrix} C(OH) \\ NH \end{smallmatrix}\rangle \rightarrow CO_2H \text{ (stable form) or}$$

$$C_8H_7\langle\begin{smallmatrix} CO \\ NH \end{smallmatrix}\rangle \rightarrow CH \cdot CO_2H \text{ (transition form) } [123^\circ].$$

Formed by saponifying its ether with fused NaOH at 180° . White crystalline pp., sl sol water. In dilute alkaline solutions it is converted into indigo by the action of air or oxidising agents. On heating it splits off CO_2 , forming indoxyl.

Indoxyllic ether $C_8H_7N(OH)CO_2Et$. Colourless prisms, $[121^\circ]$, dissolves in alkalis and is reprecipitated by CO_2 . Prepared by reduction of isatogenic ether or *o*-nitro phenyl propionic ether. Heated with H_2SO_4 , it gives indigo sulphonic acid. On oxidation it gives successively indoxanthidic ether $C_{12}H_{11}N_2O_5$, indoxanthic ether $C_{11}H_{11}NO_4$, and hydrogen ethyl oxaloxyl *o*-amido benzoate $CO_2Et \cdot CO \cdot NH \cdot C_6H_4 \cdot CO_2H$.

Acetyl indoxyllic ether
 $C_8H_7N(OAc)CO_2Et$ white needles, $[138^\circ]$
Ethyl indoxyllic ether
 $C_8H_7N(OEt)CO_2Et$ large colourless crystals, $[98^\circ]$
Ethyl-indoxyllic acid
 $C_8H_7N(OEt)CO_2H$ plates, $[160^\circ]$. Oxidised to indigo by $FeCl_3$, but not in alkaline solution.
Nitroso-ethyl-indoxyllic acid
 $C_8H_7N(NO)(OEt)CO_2H$ flat golden needles. Decomposes at about 200° . Formed by the action of nitrous acid on ethyl indoxyllic acid (Baeyer, B 14, 1742, 15, 775, 16, 2189, Forrer, B 17, 376).

INDUCTION When H and Cl are mixed in equal volumes and exposed to sunlight a measurable time elapses before chemical change begins. Bunsen & Roscoe, who examined this phenomenon (*T* 1857 355), regarded the mixture as resisting chemical change, and they used the term *induction* to express the gradual overcoming of this resistance. The term has also been used by Wright, who noticed a similar phenomenon in the reduction of metallic oxides by CO and H (*C J Trans* 1879 475, 1880 757), v **CHEMICAL CHANGE**, vol 1 p 749.

M M P M

INDULINES (O N Witt & Thomas, *C J* 43, 112). Coloured compounds formed by the action of such bodies as azo, amido azo, nitro, or nitroso-compounds on the hydrochlorides of certain aromatic amines with elimination of NH_3 . Aniline hydrochloride gives a dark-blue colouration with amido azo benzene. Hofmann & Geyger (*B* 5, 474) supposed that only one dye stuff was formed $C_{12}H_{11}N_3 + C_6H_7N = C_{18}H_{13}N_3 + NH_3$. In reality a great number of dye-stuffs are got. If the mixture of diazo benzene anilide (1 pt), aniline (4 pts), and aniline hydrochloride (1 pt), which has been left until the diazo benzene anilide has changed into amido azo-benzene, be heated at 100° for 24 hours, crystals of azophenine $C_{18}H_{13}N_3$ separate. This forms garnet coloured leaflets (from aniline) $[237^\circ]$ (v **AZOPHENINE**). If the mixture of aniline, aniline hydrochloride, and amido azo-benzene, after heating at 100° till azophenine is formed, be further heated at 125° - 130° for 12 hours, the azophenine disappears, and the mass turns blue. If it be slowly cooled crystals are formed. These may be separated from the

mother-liquor (which contains 'induline B'), washed with spirit and with boiling water, and recrystallised from aniline mixed with aniline hydrochloride. So obtained, induline B forms glistening brown leaflets, $C_{18}H_{13}N_3 \cdot HCl$. It is insol cold, sol hot, spirit, and v sol aniline. Alcoholic NaOH liberates the free base, which forms purple solutions with alcohol and with aniline. Induline B is sky blue. Its sulphonic acid resembles that of induline B.

Induline B $C_{18}H_{13}N_3$ is formed by heating a mixture of amido azo benzene (100 pts), aniline hydrochloride (130 pts), and aniline (300 pts), for 5 hours at 110° , then adding more aniline hydrochloride (65 pts), and heating to 165° - 170° . The hydrochloride, $B \cdot HCl$, separates as green crystals. The free base separates from aniline as brilliant green needles. The solution of this base is of a dark bluish purple colour. The hydrochloride is insoluble in the usual solvents, and is hardly soluble in aniline. It dissolves in phenol and in H_2SO_4 , forming a greenish blue solution.

Induline B hydrochloride is v sol spirit, sl sol water, v sol a conc aqueous solution of aniline hydrochloride. The base forms a brown red spirit solution. The sulphonic acid is insol water, but its neutral alkaline salts form reddish blue aqueous solutions.

Formation of indulines is due to the dehydrogenating action of amido azo benzene, which itself becomes aniline and *p*-phenylene diamine, the latter then entering into the reaction. Azo benzene, phenyl amido azo benzene, chrysoidine, nitroso dimethyl aniline, and even amido azo naphthalene, may be substituted for amido azo benzene, but if instead of aniline *o*-toluidine or naphthylamine be used, red dyes are got (azo toline, &c). This would indicate that azophenine was an oxidation product of aniline, and not derived from the amido azo benzene. In the preparation of azophenine by heating aniline (4 pts) with aniline hydrochloride (1 pt) and amido azo benzene (2 pts) at 85° , ammonium chloride and *p*-phenylene diamine are constant by products, indicating that phenylation and reduction of the amido azo benzene has taken place (Witt, *B* 20, 1534). When azo phenine (400 g) is boiled with alcohol (40 litres) and strong H_2SO_4 (2 kilos) for 10 hours quinone dianilide (19½ g) is formed. The compound

$$C_6H_5\langle\begin{smallmatrix} NPh \\ NPh \end{smallmatrix}\rangle$$
 is converted by heating with aniline at 100° into azophenine (Haudrows's 1, *M* 9, 414). These reactions confirm the formula

$$C_6H_5\langle\begin{smallmatrix} NPh \\ | \\ NPh \end{smallmatrix}\rangle$$
 proposed by Kimich and by

Fischer & Hepp for azophenine, which is also consistent with its formation from nitroso di-

$$\text{phenylamine } C_6H_5\langle\begin{smallmatrix} N \cdot HPh \\ | \\ N \cdot O \end{smallmatrix}\rangle \quad (\text{O Fischer \& Hepp,}$$

B 20, 2479, 21, 676, 2617). By the action of aniline on azophenine, induline (6 B) of the formula $NPh \cdot C_6H_5\langle\begin{smallmatrix} NPh \\ | \\ N \end{smallmatrix}\rangle \cdot C_6H_5$ might be formed. A mixture of 3 B and 6 B induline is formed by heating *p*-nitroso di-phenyl amine with aniline and aniline hydrochloride in alcoholic solution at 130° . By heating *p*-nitroso-di-

phenyl amine (1 pt) with aniline hydrochloride (1 to 2 pts) and aniline (4 pts) at 75° – 140° , a very rich yield of induline is obtained, which chiefly consists of 6B. If pure azophenine is heated at 140° with equal parts of aniline and aniline hydrochloride 6B induline is almost exclusively formed (Fischer a Hepp, *B* 20, 2484). By the action of azo-, nitro-, or nitroso compounds on *m*- or *p*-diamines, indulines which are soluble in water are formed, e.g. *paraphenylene blue*.

Bosinduline $C_{22}H_{19}N_3$, etc

$C_{10}H_7(NPh)_2 \xrightarrow{NPh} C_6H_5$, [225°] Formed by the action of nitroso phenyl (a)-naphthylamine hydrochloride on aniline and aniline hydrochloride at 120° (O Fischer, *B* 21, 2621). Formed also by oxidising triphenyl tri amido-naphthalene $C_{10}H_5(NHPh)_3$, [124]. Red plates, almost insol water, m sol alcohol, v sol benzene. Reduced by HI and P at 150° to a yellowish red base and aniline. Zinc and HCl give naphthalene and aniline.

Salts $\rightarrow B \cdot HCl$ 14 aq reddish brown prisms $\rightarrow b \cdot H \cdot PtCl_5$, $\rightarrow b \cdot H_2SO_4$ aq $B \cdot HNO_3$, [231°] — Picrate plates, insol water.

INDYL PHENYL KETONE CARBOXYLIC

ACID $C_{10}H_7CO_2C_6H_5 \cdot \begin{smallmatrix} CH \\ NH \end{smallmatrix} > CCO_2H$ *Benzoyl indole carboxylic acid* [285°]. From the *iso* benzoyl phenyl hydrazide of pyruvic acid by heating with $ZnCl_2$ at 220° (Ruhemann a Blackman *C J* 55, 617). White needles, sl sol boiling water. Decomposes on fusion.

INOGEN v Muscle

INOSIC ACID $C_{10}H_{11}N_3O_{11}$? Occurs in the mother liquor in the preparation of creatine from flesh (Liebig, *A* 62, 317, *A Ch* [3, 33, 129]. Occurs to the extent of $\frac{1}{2}$ pc in the flesh of hens. Pigeon's flesh and human flesh contains none (Gregory, *A* 64 106, Schlossberger *A* 66, 82). It is found in some fish (Limpricht, *A* 113, 301).

Preparation — The filtrate from which creatin has separated is concentrated, then mixed with alcohol till it acquires a milky consistence, and left to itself for a few days. It then deposits a crystalline mixture containing the inosates of Na and Ba. The crystals are dissolved in hot water and $BaCl_2$ added. The Ba salt crystallises on cooling.

Properties — Uncrystallisable, v sol water, forming a solution with a flavour of broth, whence alcohol ppt it as an amorphous powder. Insol ether.

Salts — K_2A'' 7 aq long, four sided prisms, v sol water insol alcohol — Ba_2A'' 6 aq prisms *S* 25 at 16° .

INOSITE $C_6H_7O_7$, *Phaseomannite* [217°] (Maquenne), [225° cor] (Fick) (319° in vacuo) (M) SG (of $C_6H_7O_7 \cdot 2aq$) Δ 1524 SG (of $C_6H_7O_7$) Δ 1752 S (of $C_6H_7O_7 \cdot 2aq$) 10 at 12° (T a V), 13 at 19° (Fick) H C 666500 H F 311500 (Berthelot a Recoura, *C R* 105, 14). Discovered by Scherer (*A* 73 322, 81, 375) in muscular substance (*is, iods, muscle*). It occurs especially in the heart, but also in the lungs, kidneys, liver, and spleen of oxen (Cloetta, *A* 99, 289) in the brain of oxen (W Müller, *A* 103, 140), in human kidneys, and in the urine in a case of Bright's disease to the amount of 1 p c,

and sometimes in healthy urine (Kulz, *Fr* 16, 135). Found also in birds, in cephalopoda (Krukenberg, *J Th* 1881, 343), and in the flesh of a young porpoise (O Jacobsen, *A* 157, 227). Inosite occurs in green kidney beans (*Phaseolus vulgaris*) (Vohl, *A* 99, 125, 105, 330), in the green rods and unripe seeds of peas (*Pisum sativum*), in unripe lentils (*Ervum Lens*), in the unripe fruits of the common acacia (*Robinia Pseud-Acacia*), in the heads of the common cabbage (*Brassica oleracea*, var *capitata*), in foxglove leaves, in extract of digitalis, in the leaves of the dandelion (*Taraxacum dens leonis*), in potato shoots, in green asparagus and in its berries, in *Lactaria piperatus*, in *Clavaria crocea* (Marmé, *A* 129, 222), in the leaves of the common ash (*Fraxinus excelsior*) (Gintl, *J pr* 104, 491), in grape juice (Hilger, *A* 160, 333), in young vine leaves (Neubauer, *Fr* 12, 45), in walnut leaves (Tanret a Villiers, *A Ch* [5] 23, 389, *C R* 86 486, Maquenne, *C R* 104, 225).

Preparation — 1 Walnut leaves are extracted with water. The brown liquid is treated, at 100° , with excess of milk of lime, filtered, ppd with lead acetate, again filtered and treated with ammonia and lead acetate. The crude lead compound of inosite is treated with dilute sulphuric acid, and the inosite is ppd with alcohol and ether. It can be further purified by recrystallisation from hot dilute acetic acid (Hilger, Maquenne). — 2 The fresh-chopped tissue is covered with water, and allowed to stand for 24 hours in a cool place with frequent stirring, the liquid is then separated and the residue pressed, the solution is heated with a little acetic acid to separate albumin and hæmatin, then strained, evaporated on the water bath to one tenth, ppd with neutral acetate of lead and filtered, and the filtrate is mixed with basic acetate of lead, whereupon inosite is thrown down in combination with oxide of lead, accompanied by uric acid, cystine, and other substances. The pp, after washing, is decomposed under water by H S, and the liquid filtered from the sulphide of lead, it then sometimes deposits crystals of uric acid, and when evaporated to a small bulk on the water bath, and mixed with alcohol till a turbidity is produced, it yields crystals of inosite (Cloetta). — 3 Crystals of inosite may often be obtained by evaporating an aqueous liquid containing it, and adding three volumes of alcohol to one of the boiling liquid (Cooper Lane, *A* 117 118).

Properties — Monoclinic crystals (containing $2aq$) $a \cdot b \cdot c$ 1 090 1 1535, β = $111^{\circ} 39'$. Effloresces in dry air. At 100° it gives off its water of crystallisation. It has a sweet taste and is optically inactive. Sl sol cold dilute alcohol, insol absolute alcohol and ether. Does not combine with NaCl or KCl. With lead subacetate it forms a gelatinous pp which may be $C_6H_7O_7 \cdot 2PbO$. Inosite does not react with phenyl hydrazine (E Fischer, *B* 17, 582). Inosite is not turned brown by boiling alkalis, or by boiling dilute H_2SO_4 . It does not reduce Fehling's solution but forms a green pp. It will not undergo alcoholic fermentation. In presence of decaying cheese or of putrid meat and chalk it forms butyric and lactic acids. Sodium amalgam does not affect inosite. Inosite does not form an acid solution with borax.

Reactions—1 Evaporated with *nitric acid* it leaves a residue which gives with CaCl_2 in ammoniacal solution a rose red colouration (colour test)—2 When a solution of inosite is evaporated nearly to dryness and a drop of mercuric nitrate solution is added there is formed a yellow pp which turns red on warming (Gallior, *Fr* 4, 264)—3 Heated with oxalic acid it gives CO_2 and formic acid According to Lorin (*Bl* [2] 48, 235), this indicates that it is a polyhydric alcohol—4 HIAq at 170° gives a trace of benzene, phenol, and tri iodo phenol [153°]²—5 It forms no addition products with chlorine and bromine—6 It does not reduce boiling ammoniacal AgNO_3 , but on adding KOH a mirror is formed—7 *Chromic acid* oxidises it to CO_2 and formic acid in the cold—8 KMnO_4 gives CO_2 —9 Conc HNO_3 at 100° forms oxalic acid, but in an open dish on the water bath it gives on evaporation a white substance which dissolves in water, and the solution, mixed with alcohol and evaporated, then deposits black crystals of tetra oxy quinone HNO_3 also forms rhodozone acid (Maquenne, *Bl* [2] 47, 290) According to Maquenne this reaction, and *reaction 4* indicate that inosite is hexa oxy benzene hexahydrate

Hexa-acetyl derivative $\text{C}_6\text{H}_6(\text{OAc})_6$, [212°] (23° *in vacuo*) From inosite and AcCl or Ac_2O Sublimes at 200° Insol water, sol hot alcohol and Ac_2O Saponified by alkalis and strong acids (Maquenne, *C R* 104, 1719, *Bl* [2] 48, 58) According to Fick (*C C* 1887, 452), the acetyl derivative is $\text{C}_6\text{H}_6\text{Ac}_6\text{O}_6$ and melts at 216° cor

Hexa-benzoyl derivative $\text{C}_6\text{H}_6(\text{OBz})_6$, [258°] Minute needles Insol all usual solvents

Hexa nitroxyl derivative $\text{C}_6\text{H}_6(\text{ONO})_6$, 'Nitro inosite' [120°] Formed by adding a solution of inosite in fuming HNO_3 to conc H_2SO_4 Maybe crystallised from alcohol, a crystalline tri-nitroxyl derivative being left in the mother liquor Trimetric tables, insol water, v sol alcohol Detonates when struck Cold alcoholic KOH decomposes it forming KNO_3 , the inosite being completely broken up When boiled with alcohol and a little H_2SO_4 , the products are nitrous ether and inosite

INULIN ($\text{C}_6\text{H}_{10}\text{O}_5$)_x, or $\text{C}_{72}\text{H}_{124}\text{O}_{62}$, *Helennin* *Alantinn* *Menyanthin* *Dahlin* *Synanthrin* *Sinistrin* Mol w 1980 (by Raoult's method Brown & Morris, *C J* 55 464) [160°] SG 1.35 (Kiliani), 1.36 (Payen), 1.46 (Dubrunfaut), 1.47 (Dragendorff) [a_D^{20}] = -35° (Dubrunfaut, *C R* 42, 803), -36.5° (Lescœur & Morelle, *C R* 87, 216), -40° (Lefranc, *J Ph* [5] 2, 216) HC 684900 (Berthelot & Vieille, *Bl* [2] 47, 868, *A Ch* [6] 10, 459) HF 230600 (B & V), 197000 (Von Rechenberg) A starch like substance occurring in the roots of elecampane (*Inula Helennium*) (Valentin Rose, *A D* 1804), dandelion (*Taraxacum dens leonis*), chicory (*Cichorium Intybus*), feverfew (*Pyrethrum Parthenium*), and meadow saffron (*Colchicum autumnale*), in the tubers of the potato, the dahlias, and the Jerusalem artichoke (*Helianthus tuberosus*), in Lerp manna (from *Eucalyptus dumosa*), and in certain lichens (*Lichen fraxineus* and *Lichen fastigiatus*) Sinistrin, from the sea onion (*Urginea Scilla*), is perhaps identical with inulin

Preparation—The finely divided roots are boiled v h water in presence of a small quantity of CaCl_2 . The filtrate is cooled by a freezing mixture, and, after thawing the ice, filtered again The *residue* is redissolved in hot water, and the filtered solution again subjected to the action of a freezing mixture, the process being repeated until the inulin is perfectly white The inulin is then freed from traces of levulose by treatment with 97 p.c alcohol, and is finally dried over sulphuric acid It still, however, contains about 6 p.c proteid matter corresponding to 1 p.c nitrogen, and also minute traces of inorganic substances (Kiliani, *A* 205, 147)

Properties—White powder, resembling starch Tasteless Occurs also in a gum like or horny modification, probably as a hydrate Sol cold water, v sol hot water, insol alcohol The powder is composed of minute spheres (Sachsse) It melts at 160° , becoming changed to amorphous 'pyro inulin' (Prantl, *N R* 19, 513, 577, 641) Inulin is very hygroscopic, and even when dried at 100° its composition appears to be $(\text{C}_6\text{H}_{10}\text{O}_5)_x\text{H}_2\text{O}$ (Kiliani) The aqueous solution of inulin does not form a jelly like that of starch It is not coloured blue by iodine It dissolves in cold aqueous KOH and the solution, when acidified, deposits after a while unaltered inulin It dissolves in ammoniacal cupric oxide solution (Cramer, *J pr* 73, 16) the solution yielding after a few hours a copious blue pp (Schlossberger, *J pr* 73, 373) It dissolves in an ammoniacal solution of nickel oxide It does not ppt lead acetate or sub acetate, but with a solution of lead acetate containing ammonia it gives a white pp Inulin is not pptd by salts of Fe, Cu, Hg Ag, or Au Inulin forms with alkalis unstable compounds which are soluble in water and pptd there from by alcohol When carbonised it emits an odour of burnt sugar It reduces ammoniacal gold and silver solutions, but not Fehling's solution It is not fermentable, nor is its optio activity affected by diastase It is not converted into levulose by invertin A solution of inulin dissolves PbO Baryta water gives a pp soluble in excess of a solution of inulin, and not decomposed by CO_2

Reactions—1 When heated with water at 100° it is slowly but completely converted into levulose—2 Boiling dilute acids quickly convert it into levulose—3 Dilute *nitric acid* oxidises it to racemic, oxalic, glycollic, and formic acids, but forms neither saccharic nor mucic acids (Tollens, *A* 249, 220)—4 By long contact with bromine it yields bromoform, oxalic acid, and CO_2 —5 With bromine and silver oxide it yields glycollic acid (from the intermediate formation of levulose)—6 When heated with baryta water small quantities of lactic acid are formed—7 Sodium-amalgam has no action on inulin—8 With chloro sulphuric acid (ClSO_3H) at 0° it forms $\text{C}_6\text{H}_6(\text{SO}_3\text{H})_6(\text{OCl})(a_D^{20}) = +11.5^\circ$ whence warm water produces levulose (Clausson, *J pr* 128, 27)

Acetyl derivatives These are best formulated as derivatives of $\text{C}_{12}\text{H}_{22}\text{O}_{11}$.

Tri-acetyl derivative $\text{C}_{12}\text{H}_{17}\text{Ac}_3\text{O}_{11}$ Formed by boiling inulin (1 pt) with Ac_2O (1 pt) and HOAc (2 pts) for 15 minutes (Ferrouillat & Savigny, *Z* [2] 5, 509, Lescœur & Morelle,

OR 87, 216) Amorphous yellowish mass, v sol water and alcohol, in either Lavo-ratory
Tetra acetyl derivative $C_{12}H_{11}Ac_4O_{10}$
 From inulin by heating with Ac_2O (F & S, Schützenberger, *A Ch* [4] 21, 234) Amorphous Lavo-ratory

Hexa acetyl derivative $C_{12}H_{11}Ac_6O_{18}$
 Amorphous Lavo-ratory

Hepta acetyl derivative $C_{12}H_{11}Ac_7O_{21}$
 Dextro-rotatory

Metinulin When inulin is heated with glycerin alone, or when it is heated with dilute acids, the product contains bodies resembling dextrin. They are not very soluble in water and on heating yield soluble metinulin and inuloid which are not so powerfully lavo-ratory as the unaltered inulin. Optically inactive derivatives are also formed, but they are not identical with levulosan (Höning & Schubert, *M* 8, 529). Metinulin was prepared by Dragendoff by heating inulin (1 pt) with water (5 pts) in a closed vessel, and ppg with alcohol. Inuloid is a similar or identical substance, said by Popp (*A* 156, 199) to occur in the Jerusalem artichoke. It is twice as soluble in water as inulin.

INVERTIN : FERMENTATION, vol 11 p 541

IOD or **iodo** Use of this prefix applied to inorganic compounds, for Iodo compounds and Iodo salts v the element the iodo compound of which is sought for or the salts to the name of which iodo is prefixed. Thus *stichloride of lead* will be found under *Iodine* and *iodo chromate of potassium* under *CHROMATES*.

IODATES and PERIODATES Salts of iodic and periodic acids v **IODINE**, Or acids of, pp 21, 23

IODATION v Iodo compounds

(Strecker, *W* 17, 447) S H p (20°) 1397, S H v

(100°) 1396 (Strecker, *l.c.*) I C of HI_{Aq} v Kohlrausch, *P* 159, 233 S G of HI_{Aq} saturated at 0° - 199 (De Luynes *A Ch* [4] 2, 34), 20 (Vigier, *Bl* [2] 11, 125) Vapour pressure of liquid HI at -17.8° - 2.9 atmos, at 0 - 4 atmos, at 15.5° - 5.8 atmos (Faraday, *T* 1845 170, values approx only) H F $[HI, I]$ - 60.36 gaseous H and solid I to form gaseous HI, $[H, I]$ - -436 gaseous elements at 1.0° , $[H, I, Aq]$ - 13,170 (*Th* 2, 35) HI does not occur in nature

Formation - 1 By direct union of H and I, by passing a stream of H over I at a full red heat (Courtois, *A Ch* 88, 305, Merz & Holzmann, *B* 22, 869) Cornu-vander passes H and I vapour over Pt black heated to 300° - 400° (*A Ch* [3] 80, 242, 34, 77, v also Blundell, *P* 2, 216, Lemoine, *C R* 85, 34) - 2 HI is formed by decomposing a metallic iodide by another acid, but a portion of the HI is generally decomposed with separation of I, and in some cases the HI reacts with the other acid, e.g. when H_2SO_4 is added to KI, SO_2 and H_2S are produced as well as HI and I. To prepare a solution of HI in water, Glover adds an exactly equivalent quantity of H_2SO_4 to BaI_{Aq} , and separates from ppt $BaSO_4$, (*P M* [8] 19, 92) -

3 By the reaction between Na_2SO_4 (Mène, *C R* 28, 478), or $Na_2S_2O_3$ (Gladstone, *P M* [3] 35, 345), I, and H_2O (cf formation of HBr, vol 1 p 532) - 4 By decomposing PI_3 by water (Kolbe, *J pr* 15, 172, Vigier, *Bl* [2] 11, 125, Pettenkofer, *A* 138, 57) Bieckher (*C C* 1863 207) recommends to make PI_3 by adding P to I in CS_2 and distilling off the CS_2 - 5 Etard & Moissan (*B* 18, 1862) heat I with colophony

Preparation - 1 Washed H_2S is passed into water in which a little finely powdered I is suspended ($2HI_{Aq} + 2L_{Aq} = 4HIAq + 2S$), more I is added little by little, and the passage of H_2S is continued. When all the I has been added, and no brown colour is produced on shaking the liquid, the separated S is agglomerated by briskly agitating the vessel, the liquid is filtered, H_2S is removed by gently warming, and the liquid is distilled, $HIAq$ of SG c 1.7 distils at 120° - 128° . An inverted untubulated retort with wide neck is a suitable vessel, the H_2S is passed down the neck of the retort by a tube dipping into the water in which the I is suspended. The $HIAq$ thus prepared may be used for making gaseous HI or a more conc solution. About 2 pts I are dissolved in the $HIAq$ made as described, and the solution is dropped from a tap funnel on to amorphous P (in a flask) moistened with $HIAq$ of the same concentration, the HI produced is passed through a wide U tube containing glass beads and some amorphous P moistened with $HIAq$ (to convert any I vapour into HI) $[PI_3 + 3H_2O + Aq = H_3PO_4 + 3HI]$. If dry HI is wished for, the gas is passed through a $CaCl_2$ (or better CaI_2) tube and then over P_2O_5 , and collected by downward displacement. If $HIAq$ is to be prepared, the gas coming from the first U tube is passed into the tubulus of a retort, the neck of which dips a very little way beneath the surface of water kept cold by ice; this arrangement prevents the water from rushing back into the U tube. The flask containing P in $HIAq$, into which the solution of I is dropped, should be only very gently warmed for some time, as H_3PO_4 is among the first products of the reaction, and when this is heated H_3PO_4 and PH_3 are formed, the latter of which combines with HI to form PH_4I (v Bannow, *B* 6, 1498) - 2 L Meyer recommends the following method of preparing $HIAq$ by the formation and decomposition by water of PI_3 (*B* 20, 3381) 100 g I in a retort, with the neck inclined upwards, are moistened with c 10 g water, a tap funnel (or a funnel into the neck of which fits a glass rod) is fitted into the tubulus of the retort, 5 g amorphous P and 10 g water are placed in the funnel, and a single drop of this is allowed to flow into the retort, after a little a drop or two more is allowed to follow, and a little later the liquid is added in larger quantities. HI passes off and may be collected in water as described under 1. No heating is required. If more than one drop of the P in water is added at first an explosion usually follows. The I carried over is nearly all deposited on the neck of the retort. 3 14 pts KI are warmed with 20 pts I and 1 to 1½ pts P with a little water (Müllon, *J Ph* 28, 99, Roscoe, *C J* 13, 146) - 4 Na_2SO_3 (6 pts) is rubbed up with water (1 pt), and after warming, I (3 pts) is slowly added (Mène, *C R*.

28, 478, cf Gladstone, *P M* [3] 85, 845) — 5 60 g of copaiba oil are slightly warmed in a 500 c.c. retort connected with a reversed condenser, 20 g of I are added little by little, and the temperature is allowed to rise, after a few minutes a regular and steady stream of HI comes off, when this slackens the retort is allowed to cool somewhat, more I added, and heating is recommenced, about 145 g HI may be obtained from 150 g I (Bruylants, *B* 12, 2059)

S Kemp (*P M* [3] 7, 444) says that liquid HI may be prepared by placing H persulphide in one limb of a sealed tube and a little I in the other, and gently warming the persulphide, H_2S is evolved and liquefied, and the I dissolves in the liquid H_2S , on then adding a drop of water (this is done by a special arrangement of the tube) HI is produced and liquefied, no details are given as to how the HI is separated from the H_2S

Properties — HI is a colourless, strongly acid gas, it is incombustible and extinguishes flame. Dry HI is unchanged when kept in closed tubes in the dark (Lemoine, *J* 1877 138) HI is readily liquefied (*v ante*), liquid HI is colourless (Kemp, *P M* [3] 7, 444, says it is yellowish), at -55° it solidifies to a colourless, ice like mass (Faraday, *T* 1845 170) Liquid HI is a very bad conductor of electricity (Bleekrode, *W* 3, 161, Hittorf, *W* 4, 374) HI is very soluble in water, the solution contains a strong acid, affinity of HIAq is about the same as that of HClAq (*v AFFINITY*, vol 1 p 82) HIAq is a colourless, strongly acid, fuming liquid, the solution saturated at 0° has S.G. 1.99 to 2.0, this solution gives off much HI when warmed to 40° – 50° . When HIAq containing more than c 57 p.c HI is distilled, HI is evolved until the S.G. becomes c 1.67–1.70 when the B.P. becomes approximately constant at 127° (at 774 mm.), and the liquid contains 57.0 p.c HI, if the original liquid contains less than 57 p.c HI water distils over until the acid of 57 p.c is produced, which then distils at 127° almost unchanged (Roscoe, *C J* 13, 160) By passing dry H through HIAq at 15° – 19° , an acid of constant concentration, 60.3 to 60.7 p.c HI, is obtained, at 100° the constant acid contains 58.2 to 58.5 p.c HI (Roscoe, *lc*) Topsøe gives the following S.G. and composition of HIAq (*B* 3, 403, cf Wright, *C N* 23, 242) —

Temp	S.G. referred to H_2O at same temp.	P.c HI	Temp	S.G. referred to H_2O at same temp.	P.c HI

HI is absorbed by charcoal, according to Favre 22,000 gram thermal units are produced for every 128 grams HI absorbed (*A Ch* [5] 1, 209)

Reactions — 1 HIAq is decomposed by electrolysis to H_2 and H (Riche, *J* 1858 101) 2 HI is slowly decomposed in sunlight, the decomposition proceeds without limit (Lemoine, *J* 1877 139) When mixed with oxygen and exposed to sunlight, even when the gases are dry, decomposition occurs, and proceeds the more rapidly the greater the mass of O (dry HCl and HBr are not decomposed under the same conditions) (Richardson, *C J* 51, 801) HIAq is readily decomposed with separation of I by exposure to air — 3 HI is decomposed by heat to H and I, slowly at 180° quickly a 440° (Hautefeuille, *Bl* [2] 7, 198), the dissociation of HI has been exhaustively studied by Lemoine (*v DISSOCIATION*, vol 1 p 400) — 4 Heated with oxygen H_2O and I are formed — 5 Chlorine forms HCl and I, with excess of Cl, ICl_3 is produced, bromine reacts similarly — 6 Sulphur and selenium form HI_2 or H_2Se , and iodide of S or Se (Hautefeuille, *Bl* [2] 7, 198), in presence of water I reacts with H_2S to form HIAq and S (*v PREPARATION* No 1) — 7 HI without action on amorphous phosphorus at 100° , but with ordinary phosphorus, even at the ordinary temperature, it forms P_2I_4 , HIAq slowly reacts with excess of P to produce H_3PO_4 and PH_3I ($2P + HIAq + 2.1 O = PH_3I + H_3PO_4$) (Damoiseau, *J* 1880 272) — 8 Conc. nitric acid decomposes gaseous HI instantaneously — 9 Conc. sulphuric acid forms I, and also SO and H_2S — 10 Sulphur dioxide forms S, I, and H_2O — 11 Iodic acid reacts with HIAq to form I and H_2O — 12 Very many oxidizers separate I with simultaneous formation of H_2O , e.g. H_2O_2 , $HClO_4$, $IClO_3$, chromates — 13 Many metals form iodides and evolve H , with HIAq — 14 Metallic oxides and carbonates generally form iodides and H_2O , metallic peroxides form the same products and also separate I — 15 HI produces pps of iodides when added to solutions of salts of metals which form insoluble iodides, e.g. salts of Hg, Ag, Cu, Pd — 16 Potassium permanganate produces KIO_3 — 17 HI reacts with carbon compounds generally, especially with such as contain the group OH, as an energetic reducing agent (cf Berthelot, *Bl* [2] 9, 8, 91, 173, 265)

Combinations — 1 HIAq dissolves several metallic iodides, e.g. BiI_3 , HgI_2 , PtI_2 , and PtI_4 , some of the solutions thus formed react with alkalis and alkaline hydroxides to form salts, which are probably derived from acids containing I and the metal whose iodide was dissolved in HI, e.g. by dissolving AuI_3 in HIAq and adding KOH the salt $KAuI_4$ is obtained, by similar reactions the salts Na_2PtI_6 , $MgPtI_6$, &c., are formed. Such reactions render it probable that HI combines with many metallic iodides, and that the products frequently react as acids, one or two such acidic compounds have been isolated, e.g. H_2PtI_6 , $9H_2O$ (cf BROMHYDRIC ACID, Reaction 7, vol 1 p 583, and CHLORHYDRIC ACID, Reaction 13, vol 1 p 8) — 2 HI combines with ammonia to form NH_4I , $[NH_2^+HI^-] = 43,462$ (*Th* ~, 75) — 3 With phosphine HI combines to form PH_4I , $[PH_3^+HI^-] = 24,100$ (Ogier, *C R* 89, 705)

The solution of HI in water is attended with production of much heat $[HI, Aq] = 19,207$ (*Th* 2

84) Thomsen's measurements of the heat of solution of HIAq point to the existence of a hydrate $\text{HI} \cdot \text{H}_2\text{O}$, the results are similar to those obtained for HClAq , but cannot be represented by so simple a formula (cf *CHLORHYDRIC ACID*, vol ii p 8)

The heat produced by diluting HI in $n\text{H}_2\text{O}$ with quantities of water varying from 200 to 300 H_2O is given by Thomsen as follows (Th 3, 76) —

n	$[\text{HI} \cdot n\text{H}_2\text{O}, (300 - n)\text{H}_2\text{O}]$
2	6670
3	4400
5	1830
10	630
20	220
50	70
100	30

The acids HCl , HBr , and HI are very similar in their properties and reactions. All dissolve very freely in water, forming solutions of monobasic acids, the affinities of which are great and approximately equal. All combine with certain metallic haloid compounds, especially with those of Hg , Au , Pt , and Pd , to form compounds which are best regarded as distinct acids. The thermal reactions attending the syntheses of the three acids show a gradation. Thomsen (Th 2, 39) gives the following data —

$\text{X} (\text{H}, \text{X})$ gaseous, at 180° , from gaseous elements.
 X 22,153
 Br 12,413
 I — 436
 $\text{X} (\text{H}, \text{X}, \text{Aq})$
 Cl 39,315 gaseous Cl at 19°
 Br 32,197 (calculated on assumption that Br l 18,619) and I are gaseous at 19°

Of the three acids HI is the most easily decomposed by heat and by oxidisers (cf *HALOGEN ELEMENTS*, vol ii p 665, where HF is compared and contrasted with the other halogen acids H^+X^-)

M M P M

IODHYDRIN (GLYCERIN)

Di-iodhydrin: DI IODO PROPYL ALCOHOL

IODIC ACID: IODINE Oxyacids of p 19

IODIDES Binary compounds of I with more positive elements, i.e. with any element except O , F , Cl , or Br . Iodides of almost all metals and binary compounds of I with all non metals except B , have been isolated. Most metallic iodides may be obtained by direct combination of the elements, many are obtained by heating I with metallic oxides, or by dissolving metals or their oxides in HIAq . I reacts with alkalis and alkaline hydroxides to form iodides and iodates. Some non metallic iodides are formed by direct union of the elements, e.g. iodides of H , Br , Cl , Se , S , and P . NI_3 is obtained by the reaction between I and NH_3Aq , Cl , by the reaction of AlI_3 on a mixture of CCl_4 and CS_2 . O and I combine indirectly, oxides of I are obtained by the action of oxidisers on I . The non metallic iodides as a class are more easily decomposed by heat than the chlorides or bromides, oxide of I is much more stable than oxide of Cl , and no oxide of either Br or F has yet been isolated. If two chlorides or bromides of a specified metal are known, the more stable iodide of that metal as a general rule corresponds to the lower chloride or bromide, e.g. SbCl_3 and SbCl , exist, but only SbI_3 , FeCl_3 and FeCl are stable, but I ,

FeI , exists it very easily goes to FeI_2 and I , similarly with CuI , which exists only in solution, and very readily parts with I becoming CuI , whereas CuCl_2 is more stable than CuCl . In their reactions with water metallic iodides are usually less easily decomposed than the corresponding bromides and chlorides. Metallic iodides as a class dissolve in water without change, some, however, form oxyiodides, e.g. SbI_3 and BiI_3 , and some form oxides and HIAq , e.g. SnI_2 . Metallic iodides, generally speaking, are not so readily volatilised as chlorides or bromides, most of them are unchanged by heat, but some are decomposed to metal and I , e.g. iodides of Au , Pt , and Pd . As a whole, then, the metallic iodides are not so numerous or so varied in composition as the chlorides or bromides, and they are more stable towards heat and the action of water than the chlorides and bromides, they are also less easily reduced, e.g. by H or CO , than the chlorides or bromides.

The heat of formation of a metallic iodide is usually considerably less than that of the bromide or chloride of the same metal. The following data are taken from Thomsen, —

X	$[\text{Na}, \text{X}, \text{Aq}]$
Cl	193,020
Br	171,160
I	140,600
X	$[\text{Ca}, \text{X}^2, \text{Aq}]$
Cl	187,230
Br	165,360
I	134,940
X	$[\text{Al}^3, \text{X}^3, \text{Aq}]$
Cl	475,650
Br	410,040
I	318,780

The difference between the heat of formation in aqueous solution of a chloride and the analogous bromide of the same metal is approximately 21,850, and the difference in the case of a chloride and analogous iodide is approximately 22,250. Some metallic iodides exhibit differences in crystalline form and SG, for instance SbI_3 forms hexagonal crystals, and also exists in trimetric and in monoclinic forms, CdI_2 probably exists as a white salt SG 5.644 unchanged at 250° , and also as a brownish compound SG 4.626, which begins to change at 40° (vol i p 656), there are also differences between BiI_3 according as it is prepared by sublimation or by pptn.

Iodides are usually decomposed when heated in Cl or Br with production of chlorides or bromides and I , heated in HCl they generally form chlorides and HI . Heated with conc H_2SO_4 , or conc HNO_3 , I is separated, and SO_2 (also sometimes H_2S), or NO , is evolved. I is separated from iodides by the action of many oxidising agents, such as CrO_3 , ferric salts, MnO_2 , &c.

Many metallic iodides dissolve freely in solutions of the alkali iodides, frequently with formation of double iodides. An aqueous solution of KI dissolves much I , with formation of KI_2 , but the greater part of the I thus dissolved is pptd on largely diluting the liquid. Some other periodides analogous to KI_2 are known, part of the I in such compounds is more loosely combined than the rest, and can generally be removed very easily, CuI_2 in solution, for instance,

is reduced to CuI by shaking with CS_2 . Some iodides, e.g. PtI_2 , HgI_2 , combine with HI to form compounds which are best regarded as metallic acids (H_2PtI_4 , H_2HgI_4 , &c.) Some of the resemblances and differences between the three allied classes, chlorides, bromides, and iodides, are considered in the article HALOGENS, BINARY COMPOUNDS OF THE (vol 11 p 666)

M M P M

IODINE I At w 126.53 Mol w 253.06 (*v. infra*) [113°–115°] (Stas), [114.15°] (Ramsay & Young, *C J* 49, 460) solidifies at 113.6° (Regnault, *J* 1856 41), (200°) (Stas), (184.35°) at 760 mm (B & Y, *I c*) Sublimes *in vacuo* without melting (L Meyer, *B* 8, 1627) S G 4.917 at 40.3°, 4.886 at 60°, 4.857 at 79.6°, 4.841 at 89.8°, 4.825 at 107°, 4.004 liquid at 107°, 3.866 liquid at 151°, 3.796 liquid at 170°, vol increases for 1° by 0.00235 (Billet, *J* 1855 46) ∇D c 250°–1000° 125–127, c 1500° 68 (*v Properties*, p 10) S H (solid 9°–98°) 0.5412 (Regnault, *A Ch* [2] 73, 1) S H p for I vapour at 206°–377° (equal wt of water = 1) 0.3369

(Strecker, *W* 17, 85), $\frac{S H p}{S H v}$ 1.294 at 220°–375°

(Strecker, *W* 13, 20) Heat of fusion = 11,710, heat of vaporisation = 23,950 (Favre & Silbermann, *A Ch* [3] 37, 461) For vapour pressures of solid I from 58° to 114°, and of liquid I from 114° to 185°, *v* Ramsay & Young, *C J* 49, 458 S V S 25.9 S 0.18 at 10°–12° (Wittstein, *J* 1857 123), 0.15 at 6.3° (Dossios & Weith, *Z* 1869 379) S in glycerin = 1 (Regarding solubility *v* further under *Properties*) The absorption spectrum of I vapour shows numerous fine lines extending from the red to the violet. As the thickness of the layer increases absorption becomes very marked in the red, but even when the whole of the red part is obscured, the violet portion remains without bands (Plucker, *J* 1863 109, Thalen, *P* 139, 503, *c* Conroy, *J* 1876 146, and Salet, *A Ch* [4] 28, 29) The emission spectrum shows many bright lines in the yellow-green and yellow. By using an induction current of low tension lines are seen coincident with the dark absorption lines (Salet, *I c*, Wullner, *P* 120, 158), at red heat a continuous spectrum is observed. I crystallises very easily from alcohol or HIAq , or by sublimation, the crystals are trimetric, $a b c = 4866 : 1 : 7324$ (Mitscherlich, *B* 1855 416)

Iodine was discovered by Courtois in 1811 in the mother liquor of kelp after preparation of Na_2CO_3 , Davy (*T* 1814 74) and Gay Lussac (*A Ch* 88, 311, 319, 91, 5) showed I to be an element, and established its relationship to chlorine

Occurrence—Certain mineral waters contain small quantities of free I. According to Wanklyn (*C N* 54, 300), the water of Woodhall Spa, near Lincoln, is coloured slightly brown by free I. Iodides of Na and Mg, and iodate of Mg according to Sonstadt (*C N* 25, 196, 231, 241), occur in small quantities in sea-water, alkaline iodides are found in very many mineral waters, in the ashes obtained by burning sea-plants, and some sea animals, and in certain specimens of Chili saltpetre, dolomite, phosphates, and some other minerals. Iodides of Hg, Ag, and Pb occur in small quantities in Mexico

Formation—1 By decomposing alkaline iodide by MnO_2 and H_2SO_4 , or by Cl, or by $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 , or LiNO_3 .—2 By heating an acidified solution of an iodide with $\text{FeCl}_3 \cdot \text{Aq}$. 3 By reduction; NaIO_3 by SO_2

Preparation—The greater part of the I of commerce is prepared from kelp, which is the product of burning sea plants, the kelp is lixiviated with hot water, and the liquid is evaporated in successive stages until most of the salts except NaI , Na_2S , and $\text{Na}_2\text{S}_2\text{O}_3$ have been removed. Enough H_2SO_4 is added to decompose the S compounds. After exposure to the air for some time S separates and SH_2 and SO_2 escape. The liquid is then run off and distilled with addition of more H_2SO_4 and MnO_2 , and the I is collected in a series of tubulated receivers fitted one into the other. For details of manufacture *v* DICTIONARY OF APPLIED CHEMISTRY. The I obtained as described is dried and sublimed. By slow resublimation fairly pure I is obtained, but ICy cannot thus be removed.

The chief impurities in commercial I are chlorides, water, traces of various salts, and sometimes ICy .

Stas (*Chem. Proport.* 137) gives two methods for preparing pure I.—1 KI is dissolved in its own weight of water, the solution is saturated with I (about 4 parts I are required to 1 part KI), water is added until formation of a permanent pp begins. After settling, the liquid is poured off and shaken with $\frac{2}{3}$ of the quantity of water required to bring down all the I which can be pptd by this method (the amount of water is determined by a preliminary experiment on a small quantity of the liquid). The separated I is washed by decantation until the washings are free from K, distilled with water from a large retort, allowed to drain, placed over dry Ca_2NO_3 , which is frequently changed (all other drying materials bring impurities into the I), and finally twice distilled after mixing with 5 p.c. finely-powdered pure BaO. The last traces of H_2O and traces of HI are thus removed.—2 Iodide is prepared by adding powdered I to cold conc. NH_4Aq until the dark brown liquid is nearly colourless, the compound is washed by decantation with cold conc. NH_4Aq until NH_4I is removed, placed on a funnel, the neck of which is drawn to a fine point, and covered with cold water. When the black colour of the compound changes to brownish, and the wash water is coloured yellowish brown, the moist iodide is placed in ten times its weight of water contained in a large glass balloon, and slowly heated on a water bath to 60°–65°, when decomposition occurs with formation of crystals of I, solution of I in NH_4IAq , and a white salt, which is probably NH_4IO_3 . When the change seems completed the liquid is warmed to 100° for a few minutes, if the temperature is at once raised above 65° decomposition occurs very rapidly, at 100° it proceeds with explosive violence, at the ordinary temperature the change is very slow. After cooling, the solid which separates is thrown on to a funnel with drawn out neck and washed with water, it is then distilled with water from a retort (NH_4IO_3 is not

volatilised), and the I is dried over Ca_2NO_3 , and finally by distilling with pure BaO as in '.

Recovery of iodine from laboratory residues Beilstein (*Z* 1870 528) recommends to evaporate with excess of Na_2CO_3 , to heat the residue until it is white, to add excess of H_2SO_4 , and to pass in NO oxides, obtained by heating starch with HNO_3 , until all I has separated, to wash the I in cold water, dry over P_2O_5 , and sublime slowly. The stream of NO oxides is best obtained by adding 15 grams starch to about 90 grams fairly conc HNO_3 in a large flask (the acid must not be added to the starch, else the latter may cake on the bottom of the flask and cause it to break), heating till red fumes appear, and then removing the flame and cooling from time to time, if necessary, by cold water. If insoluble iodides, e.g. HgI_2 , are present, Henry (*B* 2, 599) heats with water and granulated Zn or Fe filings, whereby soluble ZnI_2 or FeI_3 is produced. The final sublimation of the recovered I may conveniently be conducted as described by Mohr. The rim of a flat porcelain basin is ground with sand, so that a glass plate placed on the basin touches the rim in every part, the I is placed in the basin, a little finely powdered KI is strewn on the surface, the glass plate is placed in position and bound to the rim by a strip of paper, and the basin is placed on a sand tray and very slowly heated. The process of sublimation should occupy several days. If any ICl is present it reacts with the KI to give ICl and I.

Properties—A greyish black, soft, solid with metal like lustre. Perfectly pure I is described by Stas as quite black, whether solid or liquid. Only the thinnest plates of I are transparent (cf. Schultz Sellack, *P* 140, 334). I is very easily vapourised, the vapour corrodes the skin and mucous membranes, unsaturated vapour has a violet colour, saturated vapour appears deep blue in thin layers (Stas), a layer 10 centims thick is quite impervious to light (cf. Andrews, *C* N 24, 75). I vapour shows orange yellow fluorescence (Lommel, *W* 19, 356), solid I does not fluoresce (Stokes). Crystals of I polarise light (Conroy, *J* 1876 147). I is a non conductor of electricity (Jolly, *P* 37, 420). I dissolves freely in solutions of alkaline oxides and in HIAq , it is more soluble in solutions of NH_3 salts than in water. Dossios a Weith (*Z* 1869 379) give the following numbers for the S of I in KIAq

S.G. at 7°	P.c.			S.G. at 7°	P.c.		
	KI	I			KI	I	
1.0234	1.802	1.173		1.1382	8.663	7.368	
1.0433	8.159	2.303		1.1637	10.036	8.877	
1.0668	4.628	8.643		1.1893	11.034	9.949	
1.0881	5.935	4.778		1.2110	11.893	11.182	
1.1112	7.201	6.037		1.2293	12.613	12.060	

I is more soluble in solution of tannic acid than in water, addition of 0.15 parts of the acid increases S to 42 at 30° , and when 3.3 parts acid are present S is 24 at 12° (Koller, *Z* 1866 890). I is very sol in CS_2 , CHCl_3 , ether and alcohol, C_2H_6 and various hydrocarbons, also sol in SO_2 (Sestini, *Z* 1868 718), and in SO , (Weber, *J* pr 25, 224), solutions in ether or alcohol contain HI (cf. Carles, *Ph* [3] 5, 88). Addition of CS_2 to an aqueous solution of I causes withdrawal of most of the I from the water, according to Berthelot a. Jungfleisch

o 400 parts of the I go into solution in the CS_2 for each part remaining in the water (*C* R 69, 338). Solutions of I in CS_2 , CHCl_3 , C_2H_6 , and other liquid hydrocarbons are violet, solutions in ether, alcohol, and some other solvents are reddish brown. The reddish solutions absorb light in the violet end of the spectrum up to midway between D and E, conc violet solutions absorb the rays of mean refrangibility to the limits of the yellow and blue, very conc solutions absorb all rays except the ultra violet (cf. Vogel, *B* 11, 919).

The at w of I has been determined —1 By changing AgI into AgCl (Berzelius, *P* 14, 558, Dumas, *J* 1859 3) —2 By synthesis of ZnI_2 (Gay Lussac, *A* Ch 91, 5) —3 By synthesis of AgI (Marignac, *Bibl Univ Genève*, 46, 367, Stas, *Chem. Propriété*) —4 By determining the quantity of KI required to ppt a known quantity of Ag dissolved in HNO_3 (Marignac, *l.c.*) —5 By analysis of AgIO_3 (Stas, *l.c.*) —6 By determining V D of many binary compounds —7 By measuring S H of I.

Attempts have been made to determine the mol w of I in solution. Paterno a Nasini (*B* 21, 2153) measured the lowering of the freezing point of benzene and acetic acid produced by dissolving I in these liquids, the results point to the existence of molecules of I_2 in very dilute benzene solutions, and more complex molecules in more conc solutions, the numbers got with acetic acid lead to a mol w between I and I_2 . Loeb (*C* J 53, 805) determined the vapour pressure of I in solution in CS_2 and ether, ethereal solutions of I are reddish brown, solutions in CS_2 are violet, Loeb's results point to the mol w I_2 in red solutions, and a mol w between I_2 and I in violet solutions.

Determinations of the S G of I vapour, by Gay Lussac, Dumas, Bineau, Deville a Troost, up to c 1000° gave values from 8.73 to 8.62 (calc for $\text{I}_2 = 8.75$) V Meyer (*B* 13, 401, 1723, 14 1453) obtained the following results —8.86 at 293° , 8.72 at c 586° , 6.76 at c 842° , 5.75 at c 1027° , 5.7 at c 1570° . Crafts a Meier (*B* 13, 870, *C* R 92, 39) obtained similar results, the S G remained constant (8.8) to c 700° , even when pressure was diminished, but decreased above that temperature, and decreased the more rapidly the more the pressure was lowered, the S G decreased with rising temperature rapidly to a certain point and then more slowly, at a pressure of 230 mm S G became constant at 1400° – 1500° and was = 4.6, at 152 mm S G became constant at c 1400° , at 76 mm a constant value for S G was obtained at c 1350° . At c 1700° V D corresponds with molecular weight = I (Biltz a Meyer, *B* 22, 725). There can be little doubt that these results prove a gradual dissociation of I_2 into I (S G calc for I = 4.375) (cf. DISSOCIATION, vol II p 394, v also Naumann, *B* 13, 1050). The molecule I_2 is more easily dissociated than either of the molecules Br_2 or Cl_2 .

The atom of I is monovalent in gaseous molecules. I acts as a non metallic element, it is negative to all elements except O, F, Cl and Br. I combines directly with most of the metals, and with some of the non metals, e.g. H, Br, Cl, Se, S, and P, binary compounds of I with all non metals except B have been isolated. I is closely related to F, Cl, and Br, the relationship is con

sidered in the article HALOGEN ELEMENTS, vol II p 664, cf also IODIDES in this vol p 13

Reactions—1 I dissolves very slightly in water, the solution probably contains traces of HI. According to Cross a Higgins (C J 35, 225) I dissolves slightly in water at 100° in a sealed glass tube with production of a little alkaline iodide and iodate. Electrolysis of Iaq yields HIO_2Aq (Rich², J 1858 101)—2 I does not react directly with oxygen, even when I and O are heated to c 300° in presence of spongy Pt (Wehsarg, B 17, 2896) Ogier (C R 86, 722) says that if I vapour and O are subjected to the silent discharge, all the oxides of I are produced—3 *Hydrogen peroxide* produces HIAq and O, but conc HIAq is decomposed by H_2O_2 with separation of I—4 *Hydrogen sulphide* is decomposed by I in presence of water forming HI and S, dry H_2S does not react with I—5 With solutions of *caustic alkalis*, I forms alkaline iodide and iodate, according to Van Deventer a Van't Hoff, KIO is also formed (the proof of this is indirect, C C 1888 362)—6 *Ammonia gas* forms NH_4I and N (*in Combinations*, No 2), ammonia solution forms NH_4IAq and N iodide—7 When I is shaken with lime suspended in water, a bleaching liquid is obtained which reacts as if it contained Ca hypoiodite Ca(IO) and CaI_2 (Lunge a Schock, B 15, 1883)—8 I vapour heated with oxides or carbonates of the alkaline earth metals, in presence of oxygen yields periodates without formation of oxyiodides, with lead oxides various oxyiodides are produced (Cross a Sigura, C J 33, 405)—9 I is oxidised to I_2O_5 by nitric acid, chromic anhydride, chlorates, and some other oxidisers—10 I in presence of water acts as an oxidiser towards some salts and other easily oxidised compounds, arsenous oxide and arsenites are oxidised to As_2O_5 and arsenates in alkaline solutions. Sulphurous acid is oxidised to H_2SO_4 , sodium thiosulphate is oxidised to $\text{Na}_2\text{S}_4\text{O}_6$ and a little NaHSO_4 (Pickering, C J 37, 128)—11 With some carbon compounds I reacts to substitute I for H, but the HI formed tends to reproduce the original compound, so that the reactions of I with C compounds are much less marked than those of Cl and Br—12 I dissolved in CS_2 reacts with ppt *arsenous sulphide* (not with impure) to give AsI_3 and S, at a higher temp As_2S_3 and I are reformed, by distilling As_2S_3 and I in the ratio As_2S_3 6I and heating the distillate in a sealed tube to 72° (AsI_3)₂SI₂ was obtained (Schneider, J pr [2] 36, 498)

Combinations—No combination of I with H_2O has been isolated—1 With most metals, and with many non metals, especially with H, Cl, Br, S, Se, P, As. According to Holzmänn (B 22, 869) Na is scarcely attacked by I when the pure elements are heated to 300°. Fe and I combine by shaking Fe filings with I in presence of water, FeI_2 is produced, and also Fe_2O_3 and HI probably by the formation and decomposition of FeI_3 (Fleury, J Ph [5] 16, 529)—2 *Ammonia* forms several compounds with I, the dry gas is absorbed forming a dark blue liquid, the volume of NH_3 absorbed varies with temperature, at 20° it corresponds to 3NH_3 , 2I, at 80° to NH_4I , at 0° to $(\text{NH}_4)_2\text{I}_2$, at -10° to $(\text{NH}_4)_3\text{I}_3$ (Raschig, A 241, 253, cf Bineau, A Ch [3] 15, 80, Millon, A 62, 54)

Detection and Estimation—Free I is detected in solution by the colour which it gives to CS_2 or CHCl_3 ; and by the formation of a deep blue colour when a drop of starch paste is added (cf Béchamp, Fr 14 66, Mylius, B 20, 688, Personne, C R 74, 617, Duclaux, C R 74, 533, Goppelsröder, P 119, 57, Hlawetz, W A B 1867 181). In soluble iodides is detected by adding a very little Cl water, or a drop of a solution of NO_2 in conc H_2SO_4 , and then a little starch-paste. Iodates are reduced to iodides by SO_2Aq , alkaline iodates mixed with all alkali iodides and a drop of a weak acid, e.g. tartaric, give free I. Many insoluble iodides may be converted into soluble ZnI_2 by treatment with Zn and dilute $\text{H}_2\text{SO}_4\text{Aq}$. Most non metallic iodides are decomposed by water or caustic alkali giving HI or alkaline iodide. I is estimated gravimetrically by pptn as AgI , iodates are reduced by SO_2Aq and then pptd by AgNO_3Aq . Volumetrically it is estimated by titration with standard $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ or standard As_2O_3 dissolved in NaHCO_3Aq . The water in samples of ordinary I may be determined by mixing with a weighed quantity of Hg , rubbing up with a little alcohol, and carefully drying at 100°, loss of weight = water (Bolley, D P J 126, 40). The quantity of I may be determined by dissolving in a conc solution of an alkali sulphate, filtering, pptg by AgNO_3Aq , washing ppt with NH_4Aq to remove AgCl and AgBr , boiling with H_2O containing a little AgNO_3 to remove AgSO_4 , washing the residual AgI , and weighing it, after drying, in the usual manner (Hesse, A 122, 225).

Iodine, bromides of Two bromides of I are known, IBr and IBr_3 , but neither has been gasified, attempts to prepare IBr_3 , analogous to ICl_3 , have failed (Bornemann, A 189, 183). The combination of I with Br has been studied by Balard (A Ch 32, 337), Lagermark (B 7, 907), and Bornemann (A 189, 201).

Iodine monobromide IBr Formula not necessarily molecular, but probably so, from analogy to ICl which has been gasified. Prepared by heating I with rather more than the calculated quantity of Br to 25°–50° in a retort, removing excess of Br by a stream of CO_2 , and allowing to cool. Forms dark greyish, iodine like crystals, melting at 36°, probably sublimes with only partial decomposition, smells of Br, the vapour attacks the eyes and mucous membranes. The vapour appears red in thick strata (Gernez, C R 74, 1190). Soluble in alcohol, CHCl_3 , CS_2 , and ether, slowly decomposed by water with separation of I. Berthelot (A Ch [5] 21, 370) gives the H of solid IBr from solid I and liquid Br as $[\text{I}, \text{Br}] = 2470$. A hydrate $\text{IBr} \cdot 5\text{H}_2\text{O}$ described by Löwig is merely a mixture of IBr and ice.

Iodine pentabromide IBr_5 A dark brown liquid obtained by heating excess of Br with I, soluble in water, with alkali solutions forms bromide and iodate, solution in sunlight decomposes to HBr and HIO_3 .

Iodine, carbide of, better called Carbon iodide, v vol I p 689

Iodine, chlorides of I combines rapidly with Cl even at -90° (Donny a Mareska, C R 20, 817). Two chlorides of I have been isolated, ICl and ICl_3 , ICl can be gasified without decomposition, ICl_3 decomposes when heated. Kammerer (J pr 83, 83, cf B 8, 489, note) asserted

the probable existence of a tetrachloride ICl_4 , but the non existence of this compound has been proved (cf Hannay, *C J* 35, 169), Brenken (*B* 8, 187) failed to procure any higher chloride by passing Cl over strongly cooled ICl . By adding I to liquid Cl , Hannay (*C J* 35, 169) obtained a reddish liquid when the elements were present in the ratio $\text{I} : 5\text{Cl}$, but on removing pressure or raising temperature Cl was at once evolved.

IODINE MONOCHLORIDE ICl Mol w 161.9 [212°], (101°), S.G. d_4^{20} 3.18223 (Thorpe, *C J* 37, 174, H.F. [I , Cl] = 2,100 (solid ICl from gaseous Cl and solid I), 6,700 (solid ICl from gaseous constituents) (Berthelot, *A Ch* [5] 21, 170). V.D. 89.29 at 120°; 81.2 at 512° (Hannay, *C J* [2] 11, 919). Absorption spectrum of vapour v. Ger. *z.*, *C R* 74, 660.

Preparation—1 By passing dry Cl over carefully dried I till liquefaction occurs and refining by distillation with a gram or two of I . 2 By heating an intimate mixture of I with 4 parts KClO_3 and distilling the product from powdered KClO_3 ($\text{I}_2 + 3\text{KClO}_3 \rightarrow \text{KClO}_4 + \text{KIO}_3 + \text{KCl} + \text{O}_2 + \text{ICl}$)—3 By boiling I with excess of *aqua regia* diluting with water, shaking with ether and evaporating the ethereal liquid (Bunsen, *A* 54, 1).

Properties— ICl seems to exist in two forms, a reddish brown oily liquid (Ray Lussac, *A Ch* 91, 5), and a highly red solid (Schutzenberger, *Z* 5, 1). Thorpe (*C J* 37, 175) says that ICl remains liquid in a closed vessel for weeks even in a freezing mixture but solidifies on addition of a minute fragment of ICl_3 . If the liquid ICl is exposed to the air it solidifies after a time and is partially changed to ICl_3 and I (cf Hannay, *C J* [2] 11, 915; Bornemann, *A* 189, 183). According to Stortenbeker (*R T C* 7, 152), two forms of solid ICl exist one forming dark red needles melting at 27° obtained by cooling the liquid ICl to -25°, and another crystallising in dark red plates melting at +14° obtained by crystallising the liquid between -10° and +5°. ICl smells of I and Cl , it attacks all mucous membranes rapidly and forms very bad sores if let fall on the skin, decolourises indigo, does not give blue colour with starch (cf Christomanos, *B* 9, 134). ICl dissolves in alcohol, also in HClAq . Can be distilled with only very slight decomposition (Schutzenberger, *Z* 5, 1, cf Bornemann, *A* 189, 183).

Reactions—1 *Water* decomposes ICl forming HCl , HIO_3 , and I (Hannay, *C J* [2] 11, 920). According to Schutzenberger (*l.c.*) a compound IClHCl is formed (besides HIO_3 and I) by the reaction of water with ICl (cf also Trapp, *J* 1854 310, and Bornemann, *A* 189, 183)—2 *Potash solution* produces KIO_3 and KI with separation of I (H , *l.c.*)—3 *Ammonia solution* forms NH_4Cl and N iodide which combines with a portion of the NH_3 (Bunsen, *A* 84, 1)—4 Distilled repeatedly with *potassium iodide*, KCl and I are formed—5 Dissolves in *carbon disulphide*, when a saturated solution is distilled CCl_4 and CSCl_2 are formed (H , *l.c.*)—6 With many *metals* ICl reacts to form chlorides and iodides (H , *l.c.*), e.g. with Hg , Sn , Sb , Bi , Al , Mg , Na —7 With *mercuric oxide*, *cupric oxide*, and *lead peroxide*, forms chlorides and iodides

with evolution of O and separation of I —8 *Hypochlorites* and *chlorates* produce iodates with evolution of Cl (Henry, *B* 3, 892)—9 *Mercuric chloride* forms a pp of HgI_2 (Kane, *J pr* 11, 250)—10 *Stannous chloride* produces SnCl_4 and SnI_4 .

Combination—With *hydrogen chloride* to form HCl ICl , a yellow, volatile, unstable compound, produced by dissolving ICl in water, extracting with ether, and evaporating (Schutzenberger, *C R* 84, 389).

IODINE TRICHLORIDE ICl_3 Mol w unknown, decomposed by heat to ICl and Cl S.G. d_4^{20} 3.1107 (Christomanos, *B* 10, 789) [25°] (Trapp, *J* 1854 310), [33°] (Christomanos, *l.c.*) H.F. (Berthelot, *A Ch* [5] 21, 370) [I , Cl_3] = 21,700 solid ICl_3 from gaseous constituents, 16,300 solid product from solid I and gaseous Cl , [ICl , Cl_2] = 9,500 solid product from solid ICl and gaseous Cl . According to Brenken (*B* 8, 487) ICl_3 is partially decomposed when it is melted Stortenbeker (*R T C* 7, 152) gives M.P. as varying from 20° to 60°, but says that at pressure of 16 atmos the M.P. is definite and = 101°.

Preparation—1 By leading excess of dry Cl over I or ICl until yellowish red crystals are formed, and then subliming at as low a temperature as possible in a stream of Cl (Brenken *B* 8 187)—2 By the action of HCl on warm powdered HIO_3 , Cl_2 is evolved (Ditte, *A* 156, 335)—3 By the action of PCl_5 on I_2 —4 Christomanos (*B* 10, 134, 789) recommends to lead dry Cl and dry HI into a well cooled glass receiver, keeping the Cl in excess ($\text{HI} + 4\text{Cl} = \text{HCl} + \text{ICl}_3$), if HI is in excess the reaction $\text{HI} + \text{ICl}_3 = \text{HCl} + 2\text{ICl}$ occurs). To prepare small quantities of ICl_3 , say in a bulb tube Christomanos leads dry Cl through the tube, cools the place where the ICl_3 is to be deposited, then allows dry HI to stream through the tube, and finally leads dry Cl again, all parts of the apparatus being gently warmed except that where the ICl_3 is to be formed.

Properties—A citron yellow, crystalline, deliquescent solid. Very disagreeable smell, attacks the eyes and nose. Can be kept unchanged only in dry Cl (Hannay, Christomanos). In air sublimation with partial decomposition begins even at -12° (C). Complete decomposition into ICl and Cl occurs at c 70°-80° even in an atmosphere of Cl at pressure of 760 mm (Melikoff, *B* 9, 490). According to Brenken (*B* 8, 187) ICl_3 does not melt when heated, but decomposes even in an atmosphere of Cl into ICl and Cl at c 25°, the temperature varying according to the pressure. ICl_3 is sol. water, with partial change to ICl , HCl , and HIO_3 , at 100° this change occurs suddenly and completely (Bornemann, *B* 10, 121, Christomanos, *l.c.*) Sol. benzene, sol. conc. H_2SO_4 .

Reactions—1 With *water* to form ICl , HCl , and HIO_3 , in cold water a part of the ICl_3 remains unchanged, in hot water the change is complete, at 100° it occurs very rapidly—2 With *caustic alkalis*, chloride and iodide, chlorate and iodate, of the alkali are produced (Christomanos, *l.c.*)—3 With excess of *ammonia*, NH_4Cl , NH_4I , and NI_3 are formed (C)—4 *Acetic acid* produces Cl and I (C)—5 *Hydrogen iodide* in excess forms ICl and HCl (C)—6 *Carbon disulphide* produces some S chloride, the solution contains

Si_2I_2 (C) (cf Weber, P 128, 459) —7 Carbon dioxide passed over ICl_2 forms a little COCl_2 (C) 8 ICl_2Aq shaken with silver oxide forms AgCl and HIO_3 , heated with excess of Al_2O_3 , Ag peroxide (Philipp, B 3, 4) —9 Hydrogen has no action at the ordinary temperature, when the ICl_2 is slightly warmed $\text{HCl} + \text{ICl}$ are produced, at a higher temperature HCl , HI , and I are obtained (C) —10 Potassium and phosphorus burn in ICl_2 , forming chlorides and iodides (C) —11 ICl_2 oxidises hot sulphurous acid solution to SO_2Aq , and hot ferrous sulphate solution to ferric sulphate (C) —12 On carbon compounds the action of ICl_2 is to chlorinate, e.g. $\text{C}_2\text{H}_5\text{O}$, even in the dark forms $\text{C}_2\text{H}_5\text{ClO}_2$, with simultaneous production of HCl and ICl

Iodine, cyanides of Better called CYANOGEN IODIDES, v vol n p 313, and CYANURIC IODIDE, v vol n p 320

Iodine, fluoride of IF_5 A colourless, strongly smelling and fuming liquid, does not solidify at -20° , obtained by decomposing AgF by I Attacks glass and Si at red heat, no action on Hg or Pt , decomposed by water to HIO_3 and HF (Gore, C N 24, 291, MacIvor, C N 32, 232)

Iodine, hydride of, v IODHYDRIC ACID, p 11

Iodine, nitride of Better called NITROGEN IODIDE (q v in this vol)

Iodine, oxides of The only oxide of I which has been certainly isolated is I_2O_5 , the existence of IO_2 is probable Other oxides have been suggested, but the proofs of their isolation are very meagre I and O do not combine directly, Wehsarg (B 17, 2896) passed I and O over spongy Pt heated to c 300° without obtaining any compound According to Ogier (C R 86, 722) when a mixture of I vapour and O is submitted to the silent electric discharge all the oxides of I are produced I_2O_5 is the anhydride of HIO_3 , which acid is known as a definite stable solid, IO_2 (if it exists) is not an anhydride, it is said to combine with H_2SO_4 The hypothetical anhydride of periodic acid, I_2O_7 , has not been isolated The heat of formation of I_2O_5 is a large positive quantity = c 45,000 I_2O_5 is a much more stable body than any of the oxides of Cl , no oxide of Br or F has been isolated

IODINE PENTOXIDE I_2O_5 (Iodic anhydride) Mol w. unknown, as oxide has not been gasified SG ρ 4.487 (Ditte, A Ch [4] 21, 5), SG ρ 4.7987 (Kammerer, J pr 79, 94) CE $0^\circ - 51^\circ = -0.00066$ HF from solid $[\text{I}^+, \text{O}^-] = 45,029$, $[\text{I}^+, \text{O}^-] = 43,237$, $[\text{I}^{2+}, \text{O}_2^-] = -1,792$ (Th 2, 164) S = 187.4 at 13° , SG of this solution = 2.1269 (Kammerer, P 138, 390) A white crystalline solid, crystals belong to trimetric system (Schabus, J 1854 310) Produced by slowly heating dry HIO_3 to 170° Melts when heated to c 300° , with decomposition into I and O When HIO_3 crystallises from solutions containing H_2SO_4 , crystals of I_2O_5 are said to accompany the HIO_3 (Rammelsberg) Sol water, insol ether, alcohol, CHCl_3 , CS_2 , or C_2H_5 (Ditte, C R 70, 621) I_2O_5 dissolves in water to form HIO_3 The general reactions of I_2O_5 are those of an oxidiser CO passed over warmed I_2O_5 forms CO_2 and I , SO_2 gives SO_3 , H_2S produces HI , H_2O , S , and I , HCl forms ICl and H_2O , NH_3 on heating gives H_2O , N , and I (Ditte, Lc.). NO

does not react with I_2O_5 (Kammerer, J pr 79, 94)

Combinations —1 According to Kammerer (J pr 83, 72) when dry SO_2 is passed over I , heated to 100° a part of the SO_2 is oxidised to SO_3 , a little I being separated, and then a yellow crystalline compound SiO_2SO_3 is formed As soon as the compound is formed the SO_2 must be stopped The compound is decomposed by moisture, even by exposure to ordinary air Ditte (C R 70, 621) says that in this reaction only I and SO_2 are produced According to Weber (B 20, 87) the compound $\text{I}_2\text{O}_3\text{SO}_3$ is formed by heating the constituents in a sealed tube to c 60° , and pouring off excess of SO_3 , the compound is decomposed above 60° —2 By heating HIO_3 slowly to $30^\circ - 40^\circ$, or more quickly to 130° , the hydrate $3\text{I}_2\text{O}_5 \cdot \text{H}_2\text{O}$ is said to be formed Ditte, however, says this is only a mixture of I_2O_5 and HIO_3

Nitroso derivative(?) By treating perfectly dry finely powdered I with c 10 times its weight of the most conc HNO_3Aq , or a mixture of equal parts of conc HNO_3Aq and H_2SO_4 , a loose flocculent yellow powder is obtained This substance was regarded by Millon (J pr 34, 319) to be a compound of I , O , and HNO_2 , according to Kammerer (J pr 83, 65) it is $\text{I}_2\text{O}_5(\text{NO})_2$, but no analyses are given The substance is extremely unstable, it cannot be dried over CaO without decomposition it is decomposed by water to HNO_3 , HIO_3 , and I Heated in CO , NO_2 and I_2O_5 are formed

IODINE DIOXIDE or TETROXIDE IO_2 , or I_2O_4 This substance probably exists as a definite compound One part of perfectly dry I is rubbed in a basin with 10–12 pts conc HNO_3Aq SG at least 1.486, until a loose flocculent yellow powder is produced (v supra), excess of acid is poured off, the powder is placed in a funnel stopped with asbestos, and is then dried on a porous tile, and finally over lime, HIO_3 and I are then removed by washing with water and then with alcohol (Millon, J pr 34, 319, 337) IO_2 is described as a sulphur yellow powder, unchanged in air, decomposed to I and HIO_3 by heating in air to $170^\circ - 180^\circ$, insol cold water, but decomposed by boiling water giving I and HIO_3 , not acted on by alcohol Warm HNO_3 produces HIO_3 and I , but H_2SO_4 dissolves the substance, and on cooling crystals of $\text{H}_2\text{SO}_4\text{IO}_2$ separate, HClAq forms ICl and Cl , aqueous alkali solutions produce iodates, but alcoholic solutions of alkalis are said to form red liquids containing very unstable compounds

Other compounds of iodine and oxygen have been described, but it is very doubtful whether any definite compound except I_2O_5 , and probably IO , has been isolated By the action of ozone on I , Andrews & Tait obtained a yellow powder, supposed by some chemists to be I_2O (A & T Pr 9, 608, no analyses given) Ogier (C R 85, 957) asserted the formation of I_2O , by the action of ozonised O on I , he described it as a yellow deliquescent powder, decomposing at $125^\circ - 130^\circ$, with evolution of I and O , giving HIO_3 and I with water Millon (J pr 84, 336) supposed he had obtained I_2O_3 by exposing to moist air the product of boiling I_2O_5 with conc H_2SO_4 , until both I and O were coming off. Kammerer, (J pr 88, 78) treated I_2O_5 with SO_2 , and by

washing the product with alcohol and water obtained a brownish yellow powder supposed to be I_2O_5 . These substances were probably mixtures Bengieser [in 1836] (*A* 17, 2nd 4) says that by heating H_2IO_4 (*v* Periodic acid) to 160° it loses water, and that at c 180° O is evolved and I_2O_5 remains, possibly I_2O_4 may be formed at c 160° , but Rammelsberg (*J* pr 193, 278) says that decomposition of H_2IO_4 begins at 133° , and Langlois (*J* pr 56, 36) puts the decomposition temperature at 130° .

Iodine, oxyacids of. The only oxyacids of I which are certainly known are HIO_4 and H_2IO_4 , both are solids. There are indications of the existence of HIO in aqueous solution, but neither this acid nor any of its salts has been actually isolated. The periodic acid corresponding with $HClO_4$ has not been isolated, but many salts of the form MIO_4 are known, the periodates form several complex series of salts whereas all the perchlorates belong to the series $MClO_4$. HIO_4 is a product of the action of many oxidisers on I, *e.g.* HNO_3 , Cl in presence of H_2O , $KOHAq$. This acid or an iodate is also formed by digesting Mg , HgO , or Ag O with I and H_2O , or by shaking up $AgNO_3$ with an alcoholic solution of I. Electrolysis of IAq or $HIAq$ yields HIO_4 . Iodides dissolved in water are oxidised by $KMnO_4$, and by bleaching powder, to iodates. HIO_4 is produced by heating solutions of $HClO_4$, $HClO_3$, $HClO_2$, or $HBrO_3$ with I. If the reactions are compared with those whereby bromic and chloric acids are obtained (vol i p 537, and vol ii p 15) it is seen that it is more easy to pass from less oxidised, or non oxidised, compounds of I to HIO_4 , than from corresponding compounds of Cl or Br to $HClO_4$ or $HBrO_4$. The heat of formation of HIO_4 is much greater than that of HI , whereas the heats of formation of $HClO_4$ and $HBrO_4$ are considerably less than those of HCl and HBr [H , I, Aq] -13,170, [H , I, O^4 , Aq] = 55,800 (*cf* vol ii p 665) Periodic acid and its salts are stable compounds, they are more readily formed by oxidation processes than perchlorates, *e.g.* passing I vapour with O over heated BaO produces Ba periodate, and passing Cl into an alkaline iodate in presence of alkali produces an alkaline periodate. The anhydride of iodic acid, I_2O_5 , is known as a stable solid, but the anhydride of periodic acid, I_2O_7 , has not been isolated (*supra*, Iodine, oxides of).

Detection and estimation of iodates and periodates—Iodates are detected by mixing with an alkaline iodide, adding a little starch paste, and a few drops of a weak acid, *e.g.* tartaric acid, when I is set free and colours the starch blue. Periodates give a brown pp of $AgIO_4$ on addition of $AgNO_3$ in presence of HNO_3 . Periodates may be separated from iodates by ppg both as Ba salts and digesting pp with NH_3 carbonate, when Ba periodate remains unchanged, but the iodate is converted into $BaCO_3$. Iodates may be estimated by reduction to iodides by means of SO_2 or SH_2 , and pppn with $AgNO_3$, or by digesting with KI and a little HCl , when Cl is set free and decomposes the KI , giving free I which is determined volumetrically. Periodates may be estimated by a similar method (*J. Kimmins, O J* 61, 301).

Hydro iodic acid and Hydro-iodic acids Neither the acid nor any of its salts has been isolated,

According to Kōne (*P* 66, 302, Lippmann, *B* 7, 1773) the solution obtained by shaking an alcoholic solution of I with ppg HgO probably contains hypo iodic acid, but this acid quickly decomposes to HIO , and I. When I is added to $KOHAq$ or $NaOHAq$ a yellowish liquid is obtained, which bleaches indigo, gives a blue colour with starch, and is decomposed by H_2O_2 with evolution of O, on heating, iodide and iodate are formed. This solution probably contains KIO or $NaIO$ (Schönbein, *J* pr 84, 337, Berthelot, *B* 10, 900, Van Deventer a Van't Hoff, *C C* 1888 362) Lunge a Schock (*B* 15, 1883), by the action of I on CaO suspended in water, obtained a colourless solution which bleached logwood, litmus, and cochineal, gave no colour with starch, addition of acids separated I, H_2O_2 caused evolution of O, the solution decomposed slowly in the dark, more rapidly in sunlight, but even on boiling for some hours it was only partially decomposed. L a S suppose this solution to contain an I compound, analogous with bleaching powder, probably $CaOI$.

Iodic acid, and Iodates HIO_3 , MIO_3 . The acid seems to have been first obtained by Connel by oxidising I by conc nitric acid (*New Edin Philos Journ* 10, 93, 337, 11, 72, 13, 284).

Occurrence—Sometimes in commercial nitric acid (Pettenkofer, *J* 1857 581).

Formation—1 By oxidising I by very conc HNO_3 , Aq , or by $HBrO_3$, Aq (Kammerer, *J* pr 79, 94), or $HClO_4$, Aq (Davy, *S* 11, 68, 234, 16, 343)—2 By decomposing $Ba(IO_3)_2$ by the proper quantity of H_2SO_4 , Aq —3 By suspending $AgIO_3$ in water, adding an equivalent quantity of I, filtering from AgI , and evaporating to dryness ($10AgIO_3 + 12I + 6H_2O + Aq = 12HIO_4 + 10AgI$, Kammerer, *P* 138, 390). The $AgIO_3$ is prepared by ppg NH_4IO_3 by $AgNO_3$ and the NH_4IO_3 is made by digesting $Ba(IO_3)_2$ with solution of NH_3 carbonate—4 By digesting an aqueous or alcoholic solution of $AgNO_3$ with I ($10AgNO_3 + 12I + 6H_2O = 10HNO_3 + 10AgI + 2HIO_4$, Lassaigne, *J Chim méd* 9, 508, Weltzien, *A* 91, 43)—5 By decomposing KIO_4 , Aq by H_2SiF_6 , Aq , filtering, and evaporating to dryness, the product is impure—6 By leading Cl into water containing I in suspension, the greater the dilution the greater the quantity of Cl required to change all the I into HIO_4 (*cf* Bornemann, *A* 139, 183, Sodini, *B* 9, 1126)—7 By electrolyzing solution of I or HI (Riche, *C R* 46, 348)—8 By the action of Au_2O_3 on I in presence of water ($6I + 5Au_2O_3 + 8H_2O + Aq = 6HIO_4 + 10Au$, Colin, *G A* 48, 280)—9 By moistening ICl with a little water and then shaking with ether or alcohol (Liebig, *P* 24, 363)—10 Alkaline iodates are obtained by acting on I with caustic alkalis, or by oxidising alkaline iodides by $KMnO_4$, Aq or solution of bleaching powder (Hempel, *A* 107, 100, Reinige, *Fv* 9, 39, Reichardt, *Ar Ph* [3] 5, 109 $KIAq + 2KMnO_4 + H_2O = KIO_4 + 2MnO_2 + 2KOH$, Aq , $2KIAq + 5CaOCl_2$, $Aq = Ca(IO_4)_2 + 5CaCl_2$, $Aq + 2KCl$, Aq —11 $Hg(IO_3)_2$ is obtained, along with HgI_2 , by shaking I with ppg HgO suspended in water (Colin, *G A* 48 280).

Preparation—1 About 5-10 grams finely powdered I is placed in a large flask, twice it

weight of conc nitric acid SG 1.5 (not fuming acid) is added, and the bottom of the flask is gently warmed, the I is gradually oxidised, by keeping the upper parts of the flask cool any I which volatilises is prevented from escaping. After a time the acid becomes diluted, it is then poured off, fresh acid is added, and the oxidation is continued until the whole of the I has been converted into white crystals of HIO_3 . The greater part of the acid is poured off, the semi-liquid mass is evaporated to dryness in a basin, and the remaining acid is removed either by repeated evaporations with water or by heating to $100^\circ\text{--}130^\circ$ in an air current. The crystalline mass may be dissolved in water and slowly evaporated to the crystallisation point, and the crystals heated to $170^\circ\text{--}2$. Two pts conc H_2SO_4 and c 8 pts water are added to 9 pts finely powdered $\text{Ba}(\text{IO}_3)_2$, the whole is boiled for half an hour, after settling, BaSO_4 is removed by filtration, and the filtrate is evaporated until HIO_3 separates on cooling, the crystals are dissolved in water, a very little $\text{Ba}(\text{IO}_3)_2$ is added, and the liquid is evaporated and filtered. Stas says that pure HIO_3 cannot be obtained by this method, the crystals always contain either $\text{Ba}(\text{IO}_3)_2$ or H_2SO_4 . The $\text{Ba}(\text{IO}_3)_2$ required may be prepared (1) by adding BaCl_2Aq to NaIO_3Aq obtained by passing Cl into water containing I in suspension, till the I is all dissolved, then adding Na_2CO_3 till neutral, and again passing in Cl (Liebig, *P* 24, 363), (2) by suspending I in hot sat'rated BaO_3Aq and passing Cl into the liquid (Kammerer, *J* 1860 94), (3) by adding rather more than the equivalent quantity of I to hot conc KClO_3Aq , and then a few drops of nitric acid, Cl is freely evolved, and KIO_3 crystallises on cooling, the salt is recrystallised once and decomposed by BaCl_2Aq — 3 NH_4IO_3 is prepared by digesting $\text{Ba}(\text{IO}_3)_2$ with NH_4 carbonate solution, filtering, and crystallising, AgNO_3Aq is added to a solution of the NH_4IO_3 and the AgIO_3 obtained is collected and washed, the AgIO_3 is suspended in water and I is added in the ratio of 1 gram to 1.857 grams of the AgIO_3 , the reaction $10\text{AgIO}_3 + 12\text{I} + 6\text{H}_2\text{O} = 12\text{HIO}_3 + 10\text{AgI}$ proceeds when the liquid is warmed on the water bath, AgI is removed by filtration and the liquid is evaporated to dryness and the residue heated to c 170° (Kammerer, *P* 138, 390).

Properties — HIO_3 forms colourless tetrametric crystals, $a:b:c = 589:1:1903$ (Rammelsberg, *P* 90, 12), $a:b:c = 9388:1:13181$ (Schabus, *J* 1854 310). It is doubtful whether HIO_3 shows dimorphism or not (*v* Rammelsberg, *Handbuch der Krystall-physikal. Chemie*, 1 41). Thomsen gives the following thermal data (*Th* 2, 163) — $[\text{H}, \text{I}, \text{O}^*] = 57,963$, $[\text{HIO}_3^*, \text{Aq}] = -2,166$, $[\text{I}^*, \text{H}^*, \text{O}^*] = 2,540$ SG $\frac{2}{4}$ 629 (Ditte, *C R* 70, 621). Very soluble in water, most conc solution, according to Kammerer, contains 68.51 p.c. HIO_3 , boils at 100° , and has SG 2.1629. Kammerer gives the following table —

SG at 14°	P.c. HIO_3	SG at 14°	P.c. HIO_3
1.0058	1.054	1.4428	36.89
1.0263	5.27	1.5371	42.16
1.0525	10.54	1.6315	46.93
1.1223	15.81	1.7356	52.70
1.2093	21.08	1.8689	57.97
1.2173	26.85	1.9954	63.24
1.3484	31.62	2.1269	68.51

Thomsen has determined the volume change attending the dilution of HIO_3Aq . He expresses

it by the formula $V_a = 18a + 39\left(1 - \frac{a}{a+18}\right)^{13.1}$;

the composition of the solution is represented by $\text{HIO}_3, a\text{H}_2\text{O}$, the volume of one molecular weight of water is taken as 18. For optical properties of HIO_3 crystals *v* Lang, *W A B*. 31. S.H. of $\text{HIO}_3 = 1625$ (Ditte, *A Ch* [4] 21, 52). Electrolysis of HIO_3 produces I and O (Magnus, *P* 102, 1, Buff, *A* 110 257).

Reactions — HIO_3 reacts as an energetic oxidiser. 1 Most non metals are oxidised by HIO_3Aq , e.g. P to H_3PO_4 , As to H_3AsO_4 , B to HBO_3 , Si at 250° to SiO_2 (Ditte, *Bl* 1870 318), S, Se, and C are oxidised by heating in sealed tubes with HIO_3Aq , S to H_2SO_4 , Se to H_2SeO_4 , gas coke at 180° and anthracite at 210° to CO_2 , diamond is not acted on — 2 All metals, except the Pt metals and Au, are oxidised by HIO_3Aq — 3 Sulphurous acid is oxidised to H_2SO_4 , sulphuretted hydrogen to S and HI, the lower oxides of nitrogen to HNO_3 — 4 Hydrochloric acid forms ICl_3 and Cl .

Combinations — 1 With water to form $2\text{HIO}_3, 9\text{H}_2\text{O}$, obtained by cooling saturated HIO_3Aq to -17° — 2 With sulphuric acid, by dissolving HIO_3 in hot conc H_2SO_4 and cooling, crystals of $2\text{HIO}_3, 3\text{H}_2\text{SO}_4$ are said to be obtained, the mother liquor deposits other compounds of the two acids, if $\text{H}_2\text{SO}_4, 2\text{H}_2\text{O}$ is used crystals of $3(\text{H}_2\text{SO}_4, 2\text{H}_2\text{O}), 2\text{HIO}_3, 2\text{H}_2\text{O}$ are formed, these compounds are decomposed by water (Millon, *J pr* 34, 321). Crystalline bodies, supposed to be compounds (Davy), are obtained by mixing conc HIO_3Aq with solutions of H_3PO_4 and HNO_3 .

Basicity and formula of iodic acid — HIO_3 is generally looked on as a monobasic acid, analogous to HClO_3 and HBrO_3 . Besides the normal K salt there exist two acid salts, KHI_2O_6 and KHI_4O_7 , there are no chlorates or bromates similar to these. Iodic acid is easily decomposed by heat to water and the anhydride I_2O_5 , such a reaction does not usually occur with monobasic acids. Iodic acid is isomorphous with the dibasic acids, succinic and itaconic. The chlorates and bromates as a class are easily soluble in water, the iodates are very slightly soluble. The thermal phenomena attending the formation of the three acids, HClO_3 , HBrO_3 , and HIO_3 , mark off HIO_3 from the two others, thus —

$[\text{H}, \text{Cl}, \text{Aq}] = 39,320$	$[\text{H}, \text{Cl}, \text{O}^*, \text{Aq}] = 23,940$
$[\text{H}, \text{Br}, \text{Aq}] = 28,380$	$[\text{H}, \text{Br}, \text{O}^*, \text{Aq}] = 12,420$
$[\text{H}, \text{I}, \text{Aq}] = 13,170$	$[\text{H}, \text{I}, \text{O}^*, \text{Aq}] = 55,800$

The heat of formation of the acid HX decreases as the atomic weight of X increases, whereas in the series of oxyacids the heat of formation decreases from Cl to Br, but then increases very largely from Br to I. A similar variation is shown in the K salts, thus —

$[\text{K}, \text{Cl}] = 105,610$	$[\text{K}, \text{Cl}, \text{O}^*] = 95,840$
$[\text{K}, \text{Br}] = 95,310$	$[\text{K}, \text{Br}, \text{O}^*] = 84,062$
$[\text{K}, \text{I}] = 90,180$	$[\text{K}, \text{I}, \text{O}^*] = 124,489$

The iodates are not generally isomorphous with the chlorates and bromates. Thomsen says the only case of isomorphism is presented by the Ba salts. There is no doubt that the constitution of periodic acid is very different

from that of perchloric acid, but iodic acid shows some fairly marked analogies with periodic acid. Thus, if one molecular proportion of H_5IO_6 (228 grams) is dissolved in $80\text{H}_2\text{O}$ (1,440 grams), the volume of the solution is $1,440 + 60.2 = 1500.2$ cc., if the molecular weight of iodic acid is taken as $\text{H}_5\text{I}_2\text{O}_6$, and this quantity in grams (352) is dissolved in $80\text{H}_2\text{O}$, the volume of the solution is $1440 + 59.9 = 1499.9$ cc. In other words, one molecular proportion of H_5IO_6 , dissolved in 80 molecular proportions of water, produces the same expansion of the liquid as is produced by one molecular proportion of iodic acid, provided the formula of this acid is taken to be $\text{H}_5\text{I}_2\text{O}_6$. The foregoing are the chief arguments brought forward by Thomsen for establishing a difference between the constitutions of iodic acid on the one hand and chloric and bromic acids on the other hand, and for showing that iodic and periodic acids are closely related (*Th* 3, 168, 423).

The heats of neutralisation of HClO_3 , HBrO_3 , and HIO_3 are practically identical (*Th* 1, 242). When NaOHAq is added to NaIO_3 , a very small quantity of heat is developed, about 4 p.c. of the total heat of neutralisation, but the reaction of NaOH with the monosodium salt of an undoubted dibasic acid is always accompanied by the production of as much, or nearly as much, heat as attends the addition of the first molecular weight of NaOH to the acid. If iodic acid is regarded as dibasic, then the salt $\text{KH}_2\text{I}_2\text{O}_6$ must be looked on as either a compound of the normal salt $\text{K}_2\text{I}_2\text{O}_6$ with $2\text{H}_2\text{I}_2\text{O}_6$ ($2\text{KH}_2\text{I}_2\text{O}_6 = \text{K}_2\text{I}_2\text{O}_6 + 2\text{H}_2\text{I}_2\text{O}_6$), or as the acid salt of a hypothetical acid $\text{H}_4\text{I}_2\text{O}_6$.

On the whole there appear to be marked differences between the oxyacids of I and those of Cl and Br. The oxyacids of I form more complex salts than those of the other halogens. The constitution of the iodates and periodates cannot be settled by defining the basicities of the acids HIO_3 and H_5IO_6 . Several series of periodates certainly exist, and there is probably more than a single series of iodates.

The salts $\text{KH}_2\text{I}_2\text{O}_6$ and $\text{KH}_3\text{I}_2\text{O}_6$ may of course be formulated as $\text{K}_2\text{O} \cdot 2\text{I}_2\text{O}_5 \cdot \text{H}_2\text{O}$ and $\text{K}_2\text{O} \cdot 3\text{I}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$ respectively.

Iodates. These salts are formed by neutralising HIO_3 by bases, or in some cases by oxidising I in presence of a base (*v. Iodic acid*, *Formation*, Nos 10 and 11), or by double decomposition from the alkali iodates. The iodates are generally insoluble or slightly sol. in water, the alkali iodates are readily soluble, KIO_3 , however, is only slightly soluble (S at $20^\circ = \text{c } 8$). The iodates are decomposed by heat, generally giving a mixture of metallic iodide and oxide, sometimes iodide only. Solutions of iodates are more easily reduced than chlorates, reduction of KIO_3Aq is brought about by SO_2Aq or SH_2Aq , with HIAq iodates give I and metallic iodide, with HClAq they give ICl , Cl_2 , H_2O , and metallic chloride, dilute H_2SO_4 produces HIO_3 .

The following are the chief memoirs on iodates, they are referred to by numbers in the following descriptions. —(1) Bell, *J* 1871 298, (2) Berthelot, *C R* 84, 1408 (3) Cameron, *J* 1876 284 (4) Clarke, *J* 1877 48, 267 (5) Connell, *S* 62, 498 (6) Ditté, *C R* 70, 622 (7) Flight, *J* 1864 147 (8) Gay-Lussac, *G. Ammonium iodate NH_4IO_3 . Lustrous plates, decompose at 150° , S 26 at 15° , 145 at 100° S G 331-334. Formed by action of NH_3Aq on I, or of HIO_3Aq on NH_3Aq or $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ (4, 24, 28).

Barium iodate $\text{Ba}(\text{IO}_3)_2 \cdot \text{H}_2\text{O}$. By dissolving I or ICl_3 in BaOAq , or by ppg NaIO_3Aq by BaCl_2 or $\text{Ba}(\text{NO}_3)_2$. Lustrous monoclinic crystals, which lose H_2O at 130° , and when strongly heated form Ba periodate $\text{Ba}_2\text{I}_2\text{O}_6$. S G 518-528 S 07 at 135° , 15 at 100° (4, 8, 10, 12, 13, 16, 18, 24, 27).

Calcium iodate $\text{Ca}(\text{IO}_3)_2$. Occurs in seawater. Formed by adding CaCl_2Aq to KIO_3Aq , or HIO_3Aq to $\text{Ca}(\text{NO}_3)_2\text{Aq}$. By action of bleaching powder on KIAq crystallises with $6\text{H}_2\text{O}$, and from KIO_3Aq + $\text{Ca}(\text{NO}_3)_2\text{Aq}$ with $4\text{H}_2\text{O}$ (Flight). Efflorescent rhombic crystals, on heating gives mixture of CaO and Ca periodate, v insol. water (6, 16, 18, 24, 27).

Copper iodates — $\text{Cu}(\text{IO}_3)_2 \cdot 2\text{H}_2\text{O}$, greenish-blue pp by mixing conc NaIO_3Aq and CuSO_4Aq , salt with H_2O remains on warming. S 33 cold, 65 at 100° — $2 \cdot 3\text{Cu}(\text{IO}_3)_2 \cdot 3\text{CuO} \cdot 2\text{H}_2\text{O}$, by action of HIO_3Aq on strongly heated CuO . By dissolving (1) in NH_3Aq the compound $\text{Cu}(\text{IO}_3)_2 \cdot 4\text{NH}_3 \cdot 3\text{H}_2\text{O}$ is formed (18).

Mercury iodate $\text{Hg}(\text{IO}_3)_2$. By warming freshly ppg HgO with HIO_3Aq , or adding HIO_3Aq to $\text{Hg}(\text{NO}_3)_2\text{Aq}$ or $\text{Hg}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$ (not by adding HIO_3 to HgCl_2). White powder, insol water (3).

Potassium iodates — Normal iodate KIO_3 . Prepared by dissolving I in KOHAq , evaporating to dryness, and dissolving out KI by alcohol S G 81, also by passing Cl into I suspended in water, neutralising by KOHAq and evaporating. Stas adds $1\frac{1}{2}$ pts KClO_3 to semi fluid KI in a crucible, dissolves, on cooling, in hot water, and recrystallises the KIO_3 , which separates (8, 16, 17, 28). Crystallises in cubical forms S G 13 3976, KIO_3Aq S G 10741 at 19.5° contains 9.08 KIO_3 to 100 water (13). S at 5° 5.3, at 9.5° 6.7, at 14° 7.7, at 22.2° 9.2, at 45.8° 16.6, at 69.2° 27 (8). Insol alcohol S G 81. Poisonous. Decomposes, at higher temperature than KClO_3 , to KI and O , without production of KIO_4 , heated with MnO_2 forms I_2 and K_2O (8, 24, 25). KIO_3Aq shaken with finely-divided Fe gives KI (21). From solution in hot dilute $\text{H}_2\text{SO}_4\text{Aq}$ rhombic crystals of $2\text{KIO}_3 \cdot \text{H}_2\text{O}$ separate, which lose H_2O at 190° (6). The double salt $\text{KIO}_3 \cdot \text{KH}_2\text{SO}_4$ is obtained by heating KIO_3 in large excess of dilute $\text{H}_2\text{SO}_4\text{Aq}$, evaporating at 25° until $\text{KH}_2\text{I}_2\text{O}_6$ crystallises out, and further

crystallising the mother liquor (16) — 2 Di-iodate or acid iodate $\text{KH}_2\text{I}_2\text{O}_6$ (or $\text{K}_2\text{O} \cdot 2\text{I}_2\text{O}_5 \cdot \text{H}_2\text{O}$) Obtained by half neutralising HIO_3Aq by KOH Aq ; also by acidifying KIO_3Aq by HCl and H_2O by alcohol, also by dissolving KIO_3 in hot dilute HNO_3Aq (6, 18, 26) Crystallises in three forms, one rhombic and two monoclinic (16) S 1.33 at 15° (26) Solution reacts acid Insol alcohol Loses H_2O at 200° (6) Forms a double salt $\text{KH}_2\text{I}_2\text{O}_6 \cdot 2\text{KCl}$, obtained by heating KIO_3 with dilute HCl Aq , or by adding to ICl_3Aq less than enough KOH Aq to saturate it (c ratio $\text{KOH} \cdot 2\text{ICl}_3$) and allowing to evaporate (16, 24, 26) 3 Tri-iodate $\text{KH}_3\text{I}_3\text{O}_9$ (or $\text{K}_2\text{O} \cdot 3\text{I}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$) Formed by adding a large excess of HIO_3Aq to KIO_3Aq and evaporating, also by heating KIO_3 with large excess of dilute $\text{H}_2\text{SO}_4\text{Aq}$ and evaporating at 25° Large transparent triclinic crystals, lose all H_2O at 200° S 4 at 15° (6, 16, 24, 26) Berthelot (2) describes a basic iodate $\text{KIO}_3 \cdot \text{K}_2\text{O}$ obtained by heating KI in O

Silver iodate AgIO_3 Formed by ppg AgNO_3Aq by HIO_3Aq or NaIO_3Aq Crystallises from NH_4Aq in monoclinic crystals S G 5.4 Soluble without decomposition in dilute HNO_3Aq (4, 14, 16, 24, 28)

Sodium iodate NaIO_3 Prepared by saturating 10 pts water holding 1 pt I in suspension, with Cl , neutralising by Na_2CO_3 , again passing Cl , again neutralising by Na_2CO_3 and passing Cl , and so on, finally the solution is evaporated to $\frac{1}{10}$ th its bulk and mixed while warm with half its volume of alcohol, the crystals which separate are pressed and washed with alcohol till free from NaCl (15) Crystallises at under 5° with $2\text{H}_2\text{O}$, above 5° with H_2O , at 70° crystals of NaIO_3 form, hydrates with 8, 6 and 3 H_2O are also described (6, 18, 24) S 2.62 at 0° , 3.39 at 100° (13) Loses O and I when heated (15) According to Rammelsberg (24), a compound of NaI with Na_2O_2 ($6\text{NaI} \cdot \text{Na}_2\text{O}_2$) remains on heating NaIO_3 With conc HCl Aq , Cl is evolved, and a compound of HIO_3 and NaCl remains (6) Double salts with NaI are obtained by evaporating mixtures of NaIO_3Aq with NaIAq , $\text{NaI} \cdot \text{NaIO}_3 \cdot 8\text{H}_2\text{O}$, $\text{NaI} \cdot \text{NaIO}_3 \cdot 10\text{H}_2\text{O}$, and $3\text{NaI} \cdot 2\text{NaIO}_3 \cdot 20\text{H}_2\text{O}$ are described (6, 16, 19, 24) The existence of acid iodates is denied (6, 32, cf 18, 22, 26)

Besides the foregoing iodates, the following have been prepared — $\text{Cd}(\text{IO}_3)_2$ (24), $\text{Co}(\text{IO}_3)_2 \cdot \text{H}_2\text{O}$ and $\text{Co}(\text{IO}_3)_2 \cdot 6\text{H}_2\text{O}$ (4, 24), various Fe iodates (1, 5, 24), $\text{Pb}(\text{IO}_3)_2$ (23, 24), $\text{Mg}(\text{IO}_3)_2 \cdot 4\text{H}_2\text{O}$ (6, 16, 18), $\text{Ni}(\text{IO}_3)_2 \cdot \text{H}_2\text{O}$ and $\text{Ni}(\text{IO}_3)_2 \cdot 6\text{H}_2\text{O}$ (4, 24), $\text{Sr}(\text{IO}_3)_2$ (24), $\text{Zn}(\text{IO}_3)_2 \cdot 2\text{H}_2\text{O}$ Iodates of Al , Bi , Ce , Cr , Di , Au , La , Li , Mn , Sr , Sn , U , Y , and Zn also seem to exist, but they have not been fully investigated

PERIODIC ACID AND PERIODATES — The only acid which has been isolated is H_5IO_6 , but at least five distinct series of periodates are known The anhydride of periodic acid has not been obtained, when the acid is heated it loses H_2O , O , and I , and iodic anhydride, I_2O_5 , remains, Bengieser in 1836 (*A* 17, 254) stated that by heating periodic acid to 160° it lost water of crystallisation, and that O comes off rapidly at 180° , but according to Rammelsberg (*J* pr-103, 278) and Langlois (*J* pr. 56, 86) decomposition begins at $c. 180^\circ$.

Periodic acid was first prepared by Magnus a Ammermüller (*P* 28, 514), they prepared it by reacting on AgIO_3 with cold water, whereby the acid went into solution and another Ag periodate, $\text{Ag}_2\text{I}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$, remained

Formation — By the action of I on conc HClO_4Aq (Kammerer, *P* 138, 406, 410)

Preparation — 1 $\text{Na}_2\text{H}_2\text{IO}_6$ is prepared by saturating a hot solution of equal parts NaOH and NaIO_3 with Cl , concentrating, and allowing to cool (Langlois, *A Ch* 34, 257) This process yields a mixture of $\text{Na}_2\text{H}_2\text{IO}_6$ and $\text{Na}_2\text{H}_4\text{IO}_6$, the latter salt is more soluble and may be removed by long continued washing with cold water (Kimmins, *C* 51, 357), but it is not necessary to do this in preparing H_5IO_6 The Na salt is dissolved in water with addition of just enough HNO_3 to form a clear solution, and AgNO_3Aq is added, a brown pp of $\text{Ag}_2\text{H}_2\text{IO}_6$ is thus obtained (Kimmins, *C* 51, 358, former observers said that Ag_2IO_6 or $\text{Ag}_2\text{H}_4\text{IO}_6$ is produced) The brown Ag salt is suspended in water, and shaken with Br , AgBr ppts, and H_2IO_6 along with HBrO_3 goes into solution, the filtrate is evaporated to the crystallising point, whereby HBrO_3 is decomposed, and is then placed over H_2SO_4 *in vacuo* (Kammerer, *P* 138, 390) — 2 Ag HIO_4 prepared as described in 1 is dissolved in conc HNO_3Aq , and the solution is evaporated at 100° , orange red crystals of $\text{AgIO}_4 \cdot \text{H}_2\text{O}$ separate, by treatment with cold water this salt decomposes to $\text{H}_2\text{IO}_6\text{Aq}$, and $\text{Ag}_2\text{I}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$ which may be again converted into AgIO_4 by solution in conc HNO_3Aq and evaporation (Magnus a Ammermüller, *P* 28, 514) — 3 $\text{Na}_2\text{H}_2\text{IO}_6$ prepared as described in 1, and mixed with $\text{Na}_2\text{H}_4\text{IO}_6$, is dissolved in as little dilute HNO_3Aq as possible, $\text{Pb}(\text{NO}_3)_2\text{Aq}$ is added, the pp of Pb periodate ($\text{Pb}_2(\text{IO}_6)_3$, Kimmins) is digested with rather less dilute $\text{H}_2\text{SO}_4\text{Aq}$ than suffices to decompose it all, and the liquid is filtered and evaporated (Bengieser, *A* 17, 254)

Properties — H_5IO_6 crystallises in transparent, colourless prisms, probably monoclinic (Rammelsberg) M P 133° (Rammelsberg, *J* pr 103, 278), 130° (Langlois, *J* pr 56, 86), melting is accompanied by partial decomposition (Bengieser, *A* 17, 254, put the temperature of decomposition at 180°) H_5IO_6 does not lose weight at 100° , nor by keeping over H_2SO_4 Very deliquescent; fairly sol in alcohol, slightly sol in ether. Thomsen (*B* 7, 71, Th 2, 427) gives the following data for S G and expansion of $\text{H}_5\text{IO}_6\text{Aq}$ —

Ratio of H_5IO_6 , H_2O	S G of solution	Expansion for each formula-weight of acid
H_5IO_6 , $20\text{H}_2\text{O}$	1.4008	59.77
" 40 "	1.2165	59.30
" 80 "	1.1121	59.99
" 160 "	1.0570	60.2
" 320 "	1.0288	60.0

The volume when aH_5IO_6 is present is expressed by the formula $V_a = 18a + 59.8$ The following thermal data are taken from Thomsen (*Th* 2, 166) — $[\text{H}_5\text{I}_2\text{O}_7] = 185,780$, $[\text{H}_5\text{IO}_6\text{Aq}] = -1380$, $[\text{I}_2\text{O}_5\text{Aq}] = 27,000$ $\text{H}_5\text{IO}_6\text{Aq}$ exposed to air becomes yellow, and smells strongly of ozone

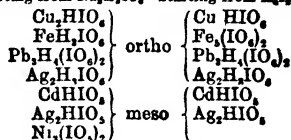

Reactions — $\text{H}_5\text{IO}_6\text{Aq}$ reacts as an energetic oxidiser, with HCl it gives Cl and HIO_4 (*M* a. A., *Lo*), with P and Bi it forms P_2O_5 and Bi_2O_3

Kammerer, *loc*); $C_2H_4O_2$, $C_2H_2O_2$, and many other acids are oxidised to CO_2 , SO_2 , Ag_2SH_2 , and HI are also oxidised, with Zn , Fe , Hg , and Cu it forms ZnO , Fe_2O_3 , HgO , and $Cu(IO_3)_2$ respectively (Bengieser, *loc*)

PERIODATES. Most of the periodates are insoluble in water, they are generally prepared from the Na or K salts by double decomposition from solutions acidified with HNO_3 . Many of them are decomposed by heat giving O and metallic iodides *e.g.* KIO_3 , $AgIO_3$, others evolve O and I , and leave either oxide, *e.g.* salts of Ni and Mg , or a mixture of oxide and iodide, *e.g.* salts of Pb , Cu , Cd . Hg salts give iodide and Hg , NH_4 salts decompose explosively to I , N , O , and H_2O . Very many periodates are known, they may be divided into several classes, the following scheme presents the chief classes and the chief salts in each class. The nomenclature is that adopted in Gmelin Kraut's *Handbuch*. All the acids except H_5IO_6 are hypothetical, formulae of salts are given here without water of crystallisation —

$Ba_3(IO_4)_2$ is obtained, and $Ca(IO_3)_2$ undergoes a similar reaction. The salts obtained by double decomposition from alkali salts of the ortho-series, *c.* of the dimeso-series, usually belong either to the ortho- or meso-series, thus the following salts are obtained —

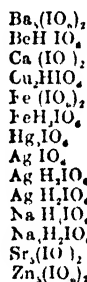

Starting from $Na_2H_2IO_4$. Starting from $K_2I_2O_8$.

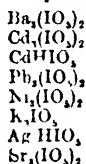

When a salt is obtained by ppn from an acidified solution of an alkali salt, the series to which the ppd salt belongs is conditioned by the relative quantity of acid present, thus when $AgNO_3$ is added to a solution of $Na_2H_2IO_4$, $K_2I_2O_8$ or KIO_3 , acidified by a little HNO_3 , Ag_2HIO_4 is obtained, when more HNO_3 is present the pp is $Ag_2H_2IO_4$, and when conc acid is pre-

PERIODATES

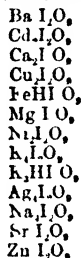

Ortho-periodates
derived from H_2IO_4 .

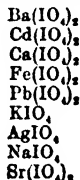

Meso-periodates
derived from H_2IO_4
($H_2IO_4 - H_2O = H_2IO_3$)

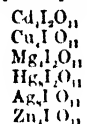

Dimeso-periodates
derived from $H_2I_2O_8$
($2H_2IO_4 - 3H_2O = H_2I_2O_8$)

Meta-periodates
derived from HIO_3
($HIO_3 - 2H_2O = HIO_2$)

Di-periodates
derived from $H_4I_2O_6$
($2H_2IO_4 - H_2O = H_4I_2O_6$)

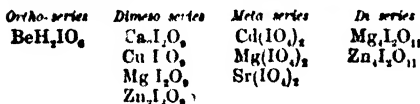

Dimeso-dimeta-periodates
derived from $H_4I_2O_6$
($2H_2I_2O_8 - 3H_2O = H_4I_2O_6$)

Trimeta-periodates
derived from $H_6I_3O_9$
($3H_2IO_3 - 10H_2O = H_6I_3O_9$)

The series to which a periodate belongs seems to depend partly on the nature of the base, and to a large extent on the conditions of preparation. By neutralising H_2IO_4 with $NaOH$ Ag Rammelsberg (P 134, 368, 499) obtained $NaIO_3$, by neutralising the same acid by various carbonates the following salts have been obtained —

By passing Cl into a hot mixture of KIO_3 and KOH , KIO_3 , $K_2I_2O_8$, and $K_2H_2IO_4$ are produced, but the Na salts formed under similar conditions are $Na_2H_2IO_4$, $Na_2H_2IO_4$, $Na_2I_2O_8$, and perhaps $NaIO_3$. By heating $Ba(IO_3)_2$ the salt

sent the salt $AgIO_3$ is obtained. Boiling salts of the ortho-, meso-, or dimeso-series with HNO_3 Ag as a rule produces salts of the meta-series. Acid salts of the ortho-series are changed to normal salts of the meso- or dimeso-series by heating, and acid salts of the meso-series are changed to normal salts of the dimeso-series, thus $Pb_2H_2(IO_4)_2$ at 275° gives $Pb_2(IO_4)_2$, and H_2O , and Ag_2HIO_4 gives $Ag_2I_2O_8$ and H_2O at 300° . Some of the periodates show very distinctly the difference between so called 'water of crystallisation' and 'water of constitution', thus Ag_2HIO_4 (which might be written $Ag_2I_2H_2O_6$) and $Ag_2I_2H_2O_6$ (which also might be written $Ag_2I_2H_2O_6$) are quite different bodies, the change $2Ag_2HIO_4 = Ag_2I_2O_8 + H_2O$ occurs at 300° , but $Ag_2I_2O_8 \cdot H_2O$ loses H_2O at 130° , again $Ag_2H_2IO_4$ (which might be written $Ag_2I_2H_2O_6$) is a dark red pp, obtained by adding $AgNO_3$ to $Na_2H_2IO_4$ in a slight excess of HNO_3 Ag,

whereas $\text{Ag}_2\text{I}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ (which also might be written $\text{Ag}_2\text{I}_2\text{H}_2\text{O}_{12}$) forms light yellow crystals, and is obtained by treating $\text{AgIO}_3 \cdot \text{H}_2\text{O}$ with water. As a rule water of crystallisation is removed at 100° , whereas the temperature of acid salts must be raised to $270^\circ\text{--}300^\circ$ before change begins with evolution of water. (For a comparison of the classes of periodates, v. Kimmins, *C J* 55, 162.) Thomsen (*Th* 1, 244) has determined the heat of neutralisation by KOH of H_2IO_6 , with the following results:—

n	$[\text{HIO}^+\text{Aq}, n \text{ KOHAq}]$	ΔH
1	5,150	21,440
2	26,590	8,150
3	29,740	2,800
5	32,040	

From these results Thomsen concludes that H_2IO_6 is dibasic, but that basic salts are produced when more than 2KOH reacts. To explain the existence of many of the periodates, Thomsen prefers to double the formula of the acid and to represent it as normally tetrabasic, thus $\text{H}_4\text{I}_2\text{O}_{10} \cdot 3\text{H}_2\text{O}$. He classifies the chief periodates as follows:—

Normal salts

Basic salts

The existence of undoubted acid salts, i.e. salts in which the H is not combined with O in the form of H_2O , militates against the classification of Thomsen. The reaction of KOH with H_2IO_6 is almost certainly a complex occurrence.

In the following description of periodates only one or two salts in each series are described in detail.

The following are the principal memoirs on periodates, they are referred to in the following paragraphs by numbers. (1) Atterberg, *J* 1873 257, (2) Bengtsson, *A* 17, 250, (3) Blomstrand, *B* 3, 817, (4) Fernlund, *J* 1867 165, (5) Groth, *P* 134, 536, (6) Kimmins, *C J* 51, 356, 55, 148, (7) Langlois, *J* 1852 345, (8) Lautsch, *J pr* 100, 65, (9) Magnus, *A* Ammermuller, *P* 28, 514, (10) Philipp, *B* 3, 4, (11) Rammelsberg, *P* 44, 545, 46, 159, 62, 416, 90, 12, 115, 584, 125, 147, 134, 568, 499, 137, 305, (12) Ritter, *Gm-X* (6th ed.), 1 [2] 303.

Ortho-series, salts derived from H_2IO_6 .

Barium orthoperiodate $\text{Ba}_2(\text{IO}_3)_2$. Prepared by heating $\text{Ba}(\text{IO}_3)_2$ in a current of dry air (Sigura *a* Cross, *C J* 36, 118), by passing I vapour and dry air over heated BaO (S *a* C), by heating BaI_2 in a current of dry air so long as I is given off (S *a* C). Insol water, sol HNO_3 Aq, heated in H gives BaI_2 and BaO .

Silver orthoperiodates—1 AgIO_3 said to be ppd as a brown salt by adding AgNO_3 Aq to a neutral solution of an alkaline periodate, also by shaking $\text{Ag}_2\text{I}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ with cold AgNO_3 Aq (11), Kimmins (6) failed to obtain this salt, sol in HNO_3 Aq and in NH_3 Aq—2 $\text{Ag}_2\text{H}_2\text{IO}_6$ dark red pp by adding AgNO_3 Aq to $\text{Na}_2\text{H}_2\text{IO}_6$ Aq or $\text{K}_2\text{I}_2\text{O}_3$ Aq in slight excess of HNO_3 (6)—

3 $\text{Ag}_2\text{H}_2\text{IO}_6$, slate coloured pp by adding AgNO_3 Aq to $\text{Na}_2\text{H}_2\text{IO}_6$ Aq or $\text{K}_2\text{I}_2\text{O}_3$ Aq in presence of a fair amount of HNO_3 (6).

Sodium orthoperiodates $\text{Na}_2\text{H}_2\text{IO}_6$ and $\text{Na}_2\text{H}_2\text{IO}_7$, white granular pps, formed by passing Cl into a bq ing solution of equal weights of NaIO_3 and NaOH , the second salt is less soluble than the first, from which it may be separated by long continued washing with small quantities of cold water (6).

For descriptions of the other salts of this series v (1) for Be salt, (6) for Cu and Fe salts, (8) for Hg salt, (11) for Ca, Sr, and Zn salts, (for formulae of salts, v p 23).

Meso series, salts derived from hypothetical H_2IO_5 .

Barium mesoperiodate $\text{Ba}_2(\text{IO}_3)_2 \cdot 6\text{H}_2\text{O}$. By ppg the corresponding K salt by Ba_2NO_3 Aq (11).

Potassium mesoperiodate $\text{K}_2\text{IO}_3 \cdot 4\text{H}_2\text{O}$. K_2IO_3 is prepared by saturating with Cl a hot conc solution of equal weights of KIO_3 and KOH , and repeatedly crystallising, the salt is dissolved in water and the solution is ppd by alcohol (11).

Silver mesoperiodate (acid salt) Ag_2HIO_5 . A dark brown pp by ppg $\text{Na}_2\text{H}_2\text{IO}_6$ or $\text{K}_2\text{I}_2\text{O}_3$ in just enough dilute HNO_3 Aq to form a solution (6).

For description of other salts of this series (formulae given on p 23), v (6) for salts of Pb and Ni, and (1*) for salts of Cd (crystallises with $5\text{H}_2\text{O}$) and Sr.

Dimeso series, salts derived from hypothetical H_2IO_4 .

Barium dimesoperiodate $\text{Ba}_2\text{I}_2\text{O}_6$. Obtained by ppg from alkali periodates in presence of HNO_3 . By neutralising H_2IO_6 Aq by BaO Aq, a salt with $7\text{H}_2\text{O}$ is obtained, which loses $4\text{H}_2\text{O}$ at 100° , and on strongly heating goes to BaIO_3 (11, 7, 8).

Ferric dimesoperiodate (acid salt) $\text{FeH}_2\text{I}_2\text{O}_6$. By ppg solution of $\text{Na}_2\text{H}_2\text{IO}_6$ or $\text{K}_2\text{I}_2\text{O}_3$ by FeCl_3 Aq and drying at 100° . Boiling with dilute HNO_3 Aq does not change this salt (6).

Potassium dimesoperiodates $\text{K}_2\text{I}_2\text{O}_6$ and $\text{K}_2\text{HI}_2\text{O}_6$. Both salts are obtained by passing Cl into KIO_3 mixed with KOH Aq (6). If equal weights of the KIO_3 and KOH are used, and the KIO_3 which separates is removed by filtration, the filtrate on concentration gives $\text{K}_2\text{I}_2\text{O}_6$, if this filtrate is exactly neutralised by HNO_3 the salt $\text{K}_2\text{I}_2\text{O}_6 \cdot 3\text{H}_2\text{O}$ (v also 11) crystallises out without concentration, if excess of HNO_3 is used, $\text{K}_2\text{HI}_2\text{O}_6$ is obtained. A solution of KIO_3 to which KOH is added is said to give triclinic crystals of $\text{K}_2\text{I}_2\text{O}_6 \cdot 9\text{H}_2\text{O}$ on concentration (5, 9). $\text{K}_2\text{I}_2\text{O}_6$ is soluble in KOH Aq, S 103 cold water, solution has alkaline reaction, Cl led into boiling $\text{K}_2\text{I}_2\text{O}_6$ Aq produces KIO_3 , with I, KI and KIO_3 are produced strongly heated leaves 2KI K_2O (11).

Silver dimesoperiodate $\text{Ag}_2\text{I}_2\text{O}_6 \cdot 3\text{H}_2\text{O}$. Light yellow crystals, obtained by treating $\text{AgIO}_3 \cdot \text{H}_2\text{O}$ with cold water (6, 9). Heated to 100° for 12 hours claret coloured crystals of $\text{Ag}_2\text{I}_2\text{O}_6 \cdot \text{H}_2\text{O}$ are formed, and when the temperature is raised to 180° and kept there for many hours a chocolate coloured powder, $\text{Ag}_2\text{I}_2\text{O}_6$, remains (6). When $\text{Ag}_2\text{I}_2\text{O}_6$ is treated with NH_3 Aq, $\text{Ag}_2\text{I}_2\text{O}_{11}$ is produced (11).

For descriptions of other salts of this series

(formulae given on p 23) v (2) for salt of Ca (crystallises with 7 and 9 H₂O), (6) for salts of Ni and Zn, (7) for Sr salt (crystallises with 3H₂O), (8) and (9) for Na salt (crystallises with 3H₂O), and (11) for salts of Cd (crystallises with 9H₂O), Cu (with 6H₂O), Mg (with 1 and 15 H₂O)

Meta series, salts derived from hypothetical HIO,

Ferric metaperiodate Fe(IO₃)₃. Bright yellow, produced by boiling FeH₂IO₆ for some time with conc HNO₃ Aq (6)

Potassium metaperiodate KIO₄. Prepared by saturating with Cl a boiling conc solution of equal parts KIO₃ and KOH, cooling, and crystallising repeatedly from water (6, 7, 9, 11) S 35 cold water, almost insol KOH Aq KIO₄ shows acid reaction At 300° forms KIO₃, decomposed by I at 160° Reduced in solution by KI to KIO₃, and I, which is then oxidised to KIO₄ (8, 9, 10)

Silver metaperiodate AgIO₄. By dissolving Na₂H₂IO₆ or Na₂H₂IO₆ or K₂H₂IO₆ in conc HNO₃ Aq and adding AgNO₃, also by treating Ag₂H₂IO₆, Ag₂H₂IO₆, or Ag₂H₂IO₆ with conc HNO₃ Aq and evaporating on steam bath Orange coloured crystals Crystals are AgIO₄, H₂O, heated to 130° for 6 hours AgIO₄ remains as a bright yellow powder (6) Decomposed by water giving Ag₂IO₄, 3H₂O (11)

For descriptions of other salts of this series (formulae given on p 23) v (11) for salts of Ba, Cd, Ca, and Sr (crystallises with 6H₂O), (5), (7), (8), (9), and (11) for salt of Na (crystallises with 2 and 3 H₂O)

Di series, salts derived from hypothetical H₂I₂O₁₁

Cadmium diperiodate Cd₂I₂O₁₁, 3H₂O By prep a slightly acidulated solution of NaIO₃ by a soluble Cd salt (11)

Silver diperiodate Ag₂I₂O₁₁. By treating Ag₂I₂O₁₁ with NH₃ Aq (8, 11)

For descriptions of the other salts of this series (formulae given on p 23) v (11) for salt of Cu (crystallises with H₂O and 7H₂O), (11) for salt of Mg (with 6 and 9 H₂O), (11) for salt of Hg (cf 8), (7) for salt of Zn (cf 11)

Dimeso di and Tri meso series, salts derived from hypothetical H₂I₂O₁₁, and H₃I₃O₁₅, respectively, v (8) and (11)

Iodine phosphides of, better called *Phosphorus iodides*, v PHOSPHORUS

Iodine selenides of, better called *Selenium iodides*, v SELENIUM

Iodine silicides of, better called *Silicon iodides*, v SILICON

Iodine sulphides of, better called *Sulphur iodides*, v SULPHUR

Iodine tellurides of, better called *Tellurium iodides*, v TELLURIUM M M P M

iodo acetic acid C₂H₃IO₂, s.e.

CH₂IC₂H₃ fol w 186 [82°]

Formation—1 By digesting bromo acetic ether with KI and alcohol, for about two hours in the dark, distilling off the resulting iodo-acetic ether and decomposing it with baryta-water (Perkin A Duppa, P M [4] 18, 54)—2 By boiling Ac₂O with iodine and iodic acid (Schützenberger, J pr 107, 108)—3. By the oxidation of iodo-acetic aldehyde (Chautard, A Ch [6] 16, 162)

Properties—Trimetric plates, decomposed by heat

Reactions—1 Moist silver oxide yields glycolic acid—2 Resolved by HI, even in the cold, into acetic acid and free iodine (Kekulé, C J 17, 207)

Salts The NH₄ and K salts are very soluble, crystalline, and non deliquescent—BaA', crystalline, m sol water, ppd from aqueous solution by alcohol—PbA', prisms In solution it easily splits up into PbI₂ and glycolic acid

Methyl ether MeA' (170°) Pungent liquid (Aronstein & Kramps, B 14, 604)

Ethyl ether EtA' (180°) From bromo-acetic ether, KI, and alcohol (P a D) Also from chloro acetic acid, KI, and alcohol (96 p a) by heating on the water bath in the dark Easily obtained by heating chloro acetic ether with CaI₂ 3 aq at 75° (Spindler, A 231, 272) Pungent heavy oil Decomposed by EtI at 230° giving acetic ether and ethylene iodide (Aronstein & Kramps, B 13, 489, 14, 604) With Me₂S it forms MeS CH₂ CO₂H and, finally, S(CH₂CO₂H)₂

Chloro ethyl ether ClCH₂CH₂OCOCH₃ S G 15 1954 From chloro ethyl chloro acetate by gently heating with an alcoholic solution of NaI (Henry, C R 97, 1308) Very pungent oil Turns brown in daylight

Propyl ether PrA' (198°) S G 15 1679 From propyl chloro acetate and alcoholic NaI (Henry, C R 100, 114) Pungent oil

Amide CH₂IC₂ONH₂ [158°] Formed from methyl iodo acetate and alcoholic NH₃ (Henry) Also from chloro acetamide and alcoholic KI, by standing a few days in the cold (Menschutkin a Fersolajeff, Z 1571, 5) Small needles or prisms

Nitrile CH₂IC₂NC *Iodo acetonitrile* (187°) S G 15 2307 From chloro acetonitrile and alcoholic NaI (Henry, C R 103, 413) Colourless, very pungent oil, which becomes brown in daylight V sol alcohol and ether Slightly decomposed on distillation, with liberation of some iodine and HCN AgOAc forms CH₂(OAc)CN

Di iodo acetic acid CHL₂CO₂H Formed by heating di bromo acetic ether with KI, converting the resulting di iodo acetic ether into a Ca salt with milk of lime, and adding HCl (Perkin A Duppa, C J 13, 1) Crystalline sulphur yellow compound, volatile in the cold, s sol water Does not blister the skin The K and Na salts are deliquescent—BaA', trimetric crystals, giving off iodine when heated—CaA', silky yellow needles—PbA', crystalline pp—AgA' yellow crystalline powder

Ethyl ether EtA' Formed by treating di chloro acetic ether with CaI₂ 3 aq at 75° (Spindler, A 231, 278) Formed also by adding iodine to a solution of diazo acetic ether in ether (Curtius, J pr [2] 38, 433) Oil, volatile with steam, reddens on exposure to air

Amide CH₂IC₂CONH₂ [202°] Formed by the action of iodine upon a cold alcoholic solution of diazo acetamide (Curtius, B 15, 1286) Formed also by the action of conc NH₃ Aq upon di-iodo-acetic ether Greenish-white prisms (from hot water), v sol water. Very stable towards acids and alkalis.

IODO ACETIC ALDEHYDE $\text{CH}_2\text{I CHO}$ S G

12 2 14

Formation—1 By boiling an aqueous solution of chloroacetic aldehyde with KI, allowing to stand for 12 hours, and then extracting with ether (Glinksky, *Z* [2] 4, 618)—2 By the oxidation of a solution of iodine in alcohol

Preparation—By mixing iodine (50 g), iodic acid (20 g), aldehyde (30 cc) and water (60 cc) and leaving the closed flask to stand for about a week (in summer) Water (500 cc) is then added, when the iodoacetic aldehyde separates as an oil (Chautard, *A Ch* [6] 16, 145, *C R* 102, 118, *C N* 54, 87, cf W P Bloxam & E F Herroun, *C N* 53, 301, 54, 133)

Properties—Limpid colourless oil, uninflammable. Blackens rapidly when exposed to light. Its vapour is excessively irritating. Cannot be distilled even *in vacuo*. Decomposes at 80°. Miscible with alcohol, ether, chloroform, and CS_2 . Soluble in water. Forms a crystalline hydrate. Forms a crystalline compound with NaHSO_4 .

Reactions—1 Dilute aqueous KOH forms iodoform. Conc KOH aq resinifies it.—2 *Ammonia* either aqueous or alcoholic forms ammonium iodide and various bases, e.g. oxytriethylamine ($\text{C}_2\text{H}_5\text{O}$), $\text{N C}_2\text{H}_5\text{OH}$ —3 *Chlorine and bromine* at ordinary temperatures displace iodine giving chloro and bromoacetic aldehydes and resins.—4 All mineral acids decompose iodoacetic aldehyde.—5 *Reducing agents* (Na amalgam, Zn and HCl) remove the iodine.—6 *Oxidation* with HNO_3 yields $\text{CH}_2\text{I CO}_2\text{H}$ [82°]—7 NaOEt and KOEt yield only resinous matters.—8 *Silver acetate* yields acetic ether (74°)—9 AgCN gives $\text{CH}_2(\text{CN})\text{CO}_2\text{H}$ —10 AgSCN similarly gives $\text{CH}_2(\text{SCN})\text{CO}_2\text{H}$ —11 *The amines* form crystalline bases with elimination of water. Thus aniline gives $\text{CH}_2\text{I CH}(\text{NH}_2\text{C}_6\text{H}_5)$, and *p*-toluidine gives $\text{CH}_2\text{I CH}(\text{NH}_2\text{C}_6\text{H}_4\text{CH}_3)$.

Tri-iodoacetic aldehyde CHI_3CHO *Iodal* (above 200°). From chloral or bromal and HI (Bertrand, *J* 1881, 588)

IODO-ACETO ACETIC ETHER

$\text{CH}_3\text{CO CH}_2\text{CO}_2\text{Et}$ S G 14 17053 From cupric acetoacetic ether and iodine in ether (Schönbrodt, *A* 253, 178). Yellowish oil, v sol ether. Begins to decompose at 25°. AgCl gives chloroacetoacetic ether. AgCy gives di-oxyterephthalic ether dihydride. AgNO_3 forms nitroacetoacetic ether. Reduced silver gives diacetyl-fumaric ether. Sodium acetoacetic ether in benzene forms diacetyl succinic ether.

IODO ACETONE $\text{C}_2\text{H}_5\text{IO}$ i.e. $\text{CH}_3\text{CO CH}_2\text{I}$ S G, 12 2 17 Formed by the action of KI on chloroacetone (Glutz & E Fischer, *J pr* [2] 4, 52). Prepared by mixing acetone (200 cc) with iodine (100 g) and iodic acid (10 g), and, after a week, boiling for three hours, adding water (500 cc), drying the separated oil over CaCl_2 , and distilling *in vacuo* in the dark (De Clermont & Chautard, *C R* 100, 745). Very pungent oil. Not inflammable. Decomposes slowly in sunlight, but more rapidly when heated. Reduces Fehling's solution. Mineral acids convert it into $\text{CH}_2\text{I CO CH}_2\text{I}$. Silver chloride forms chloroacetone. LiOAc gives $\text{CH}_3\text{CO CH}_2\text{OAc}$.

Di iodoacetone $\text{C}_2\text{H}_4\text{I}_2\text{O}$ i.e. $\text{CH}_2\text{I CO CH}_2\text{I}$ [62°] (M Simpson, *J pr* 102, 380, O Völker, *A* 192, 90).

Formation—1 From acetone (48 g), water (1000 g), and ICl_3 (96 g) at 68°. As soon as reaction begins the liquid is cooled. The oil that separates is exposed to the air till crystals separate (eight weeks), these are recrystallised from alcohol.—2 From $\text{CH}_2\text{I CO CH}_2\text{I}$ and aqueous KI.

Properties—White needles. Violently attacks the mucous membrane. Decomposed when heated. Not very soluble in chloroform, CS_2 , or alcohol. Soluble in benzene, v sol ether and acetone. Cannot be distilled undecomposed.

Reactions—1 *Silver chloride* gives solid $\text{CH}_2\text{I CO CH}_2\text{I}$ [43°]—2 Decomposed by cold KOH, and by boiling K_2CO_3 —3 Not converted into acrolein or acrylic acid by Ag_2O , AgCy , or HgO —4 HgI_2 forms acetone, iodic acetone, HI, and acetic acid, but no acrolein—5 *Zinc* and *acetic acid* reduce it to acetone.

p IODO ACETOPHENONE

[14] $\text{C}_6\text{H}_4\text{I CO CH}_3$ [79°] Obtained by diazotising *p*-amidoacetophenone, and heating the diazo-chloride with excess of HI (Klingel, *B* 18, 2692). White flat needles or plates. Easily sol alcohol and ether, and to a certain extent in hot water. By CrO_3 it is easily oxidised to *p*-iodo benzoic acid [266°].

IODO-ACETOTHENONE v Iodo THIENYL**MPHTHYL KETONE**

IODO ACETYLENE HC CI Formed by passing a current of steam through a solution of barium iodo-propargylate ($\text{C}_3\text{H}_3\text{O}$) $_2\text{Ba}$ (Bayer, *B* 18, 2271). Crystalline solid. Sol water. Volatile with steam. Very poisonous. It gives a purple red pp with ammoniacal Cu_2Cl_2 , which is soon converted by an excess of the copper solution into copper acetylene and cuprous iodide. It soon polymerises on keeping.

Di iodoacetylene I C CI [78°] Formed by the action of iodine upon acetylene silver. By treatment with an excess of ammoniacal Cu_2Cl_2 it is converted into copper acetylene and cuprous iodide. It readily polymerises (Bayer, *B* 18, 2275).

Di iodo diacetylene I C C C I [101°] Colourless crystals. Odour resembling iodoform. Formed by the action of a solution of iodine in aqueous KI upon silver diacetylene. By treatment with an excess of ammoniacal Cu_2Cl_2 it yields copper diacetylene and cuprous iodide. It explodes violently on heating, with a brilliant red flash. It soon polymerises on keeping (Bayer, *B* 18, 2276).

IODO ACETYLENE CARBOXYLIC ACID**IODO PROPIONIC ACID****IODO ACIDS** v IODO COMPOUNDS

IODO ACRYLIC ACID $\text{C}_3\text{H}_3\text{IO}_2$ Large, colourless, four sided prisms [65°], or plates [140°]. Easily soluble in water, alcohol, and ether. Formed by the addition of HI to propiolic acid (Bandrowski, *B* 15, 2703, Stolz, *B* 19, 542). The Pb and Ag salts are white crystalline pps.

Di iodo-acrylic acid $\text{CHI CI CO}_2\text{H}$ [106°]. Formed by treating propiolic acid with an ethereal solution of iodine (Homolka & Stolz, *B* 18, 2284). Colourless prisms, or long needles. Volatile with steam. Easily soluble in alcohol, ether, and hot water.

Di iodo-acrylic acid $\text{I C CH CO}_2\text{H}$ [133°]. Formed by addition of HI to iodo propiolic acid.

$\text{IO}_2\text{C.CO}_2\text{H}$ (Homolka & Stolz, *B* 18, 2284)
Prisms Easily soluble in alcohol and ether, tolerably in hot water, very sparingly in cold Not volatile with steam

Tri-iodo-acrylic acid $\text{Cl}_3\text{C.CO}_2\text{H}$ [207°]
Formed by the action of an ethereal solution of iodine upon iodo-propionic acid $\text{ClC.CO}_2\text{H}$ (Homolka & Stolz, *B* 18, 2286) Large colourless prisms Easily soluble in alcohol and ether, insoluble in cold water

iodo-di allyl-acetic acid $\text{C}_6\text{H}_9\text{IO}_2$ *i.e.* $\text{Cl}(\text{C}_6\text{H}_7)\text{CO}_2\text{H}$ Iodo octenoic acid From $\text{C}(\text{OH})(\text{C}_6\text{H}_7)\text{CO}_2\text{H}$ and fuming HIAq (Schatzky, *J R* 17, 78) Crystals, insol water, v sol alcohol and ether Easily decomposes

iodo allyl alcohol $\text{C}_3\text{H}_5\text{IOH}$ [160°]
Produced by the action of aqueous Na_2CO_3 on di iodo propyl alcohol (Hübner & Lellmann, *B* 18, 460) Needles Highly volatile with steam Insol water, sol alcohol, chloroform, and HOAc Not attacked by Ac_2O

iodo allylene $\text{C}_3\text{H}_4\text{I}_2$ *i.e.* $\text{CH}_2\text{C}(\text{Cl})_2$ (?) (98°) SG 17 From silver allylene and iodine in KIAq (Liebermann, *A* 135, 270) Pungent oil Almost insol alcohol With zinc and HCl it gives off allylene Combines with iodine (1 mol)

Iodo allylene $\text{CH}_2\text{I.CCH}$ Propargyl iodide (115°) SG 2 20177 From propargyl bromide and alcoholic NaI (Henry, *B* 17, 1132) Liquid V e sol alcohol and ether, m sol cooling water Readily combines with iodine, forming colourless needles of $\text{CHI.CI.CH}_2\text{I}$ [41°] Combines with mercury

iodo allylene iodide v **Tri-iodo propylene**

Tri-iodo-allyl ethyl oxide $\text{C}_6\text{H}_9\text{IO}_3$ *i.e.* $\text{Cl}_3\text{C.CI.CH}_2\text{OEt}$ From the silver derivative of propargyl ethyl oxide and iodine in ethereal solution (Liebermann, *A* 135, 285) Oil

Di iodo allyl iodide v **Tri iodo propylene**

Tetra-iodo-di-allyl phosphite
 $(\text{CHI.CI.CH}_2\text{O})_2\text{P}(\text{OH})$ [49°] From propargyl alcohol, iodine, and red phosphorus (Henry, *B* 8, 398, 17, 1133) Long slender needles (from alcohol) Very pungent

iodo-amido-benzoic acid $\text{C}_6\text{H}_4\text{INO}_2$ *i.e.* $\text{C}_6\text{H}_4(\text{NH}_2)\text{CO}_2\text{H}$ [3 2or6 1] [137°] Formed by reducing iodo nitro benzoic acid [235°] dissolved in glacial acetic acid (Grothe, *J pr* [2] 18, 326) Dark brown crystals V sol water By further reduction it forms o-amido benzoic acid [143°] — HA'Cl — BaA' , aq

Iodo-amido-benzoic acid $\text{C}_6\text{H}_4(\text{NH}_2)\text{CO}_2\text{H}$ [8 6or2 1] [209°] From iodo nitro benzoic acid [174°] Needles, sl sol water May be reduced to o-amido benzoic acid — CaA' , 2aq — BaA' , — BaA' .

Di-iodo-m-amido benzoic acid
 $\text{C}_6\text{H}_3\text{I}_2(\text{NH}_2)\text{CO}_2\text{H}$ Formed, together with $\text{N}(\text{C}_6\text{H}_4\text{I.CO}_2\text{H})_2$, by treating an alcoholic solution of m-amido benzoic acid [173°] with iodine and mercuric oxide (Beydick, *B* 8, 384) The acids are separated by fractional ppn of their alcoholic solution by lead acetate Long needles Decomposed by heat Insol water, v sol alcohol, ether, aqueous acids, alkalis, and Na_2CO_3 — KA' long silky needles, obtained by mixing alcoholic solutions of the acid and KOH .

Di-iodo-p-amido-benzoic acid
 $\text{C}_6\text{H}_3\text{I}_2(\text{NH}_2)\text{CO}_2\text{H}$ [above 300°] Obtained by dissolving p-amido benzoic acid in dilute HCl and passing in the vapour of ICl (2 mols) (Michael & Norton, *Am* 1, 264) Tables Insol water, alcohol, and HOAc , sol nitro-benzene Does not combine with acids — NaA' , 5aq long white needles, sol hot water. — BaA' , 4aq needles, sol hot water — AgA'

DI IODO-p AMIDO PHENOL
 $\text{C}_6\text{H}_3\text{I}_2(\text{NH}_2)\text{OH}$ [222°] Formed by reducing the corresponding nitro phenol with SnCl_2 and HCl (R Seifert, *J pr* [2] 28, 437) Needles (from alcohol) or plates (from MeOH) With HCl and bleaching powder it gives di-iodo quinone chloride (*q v*) With H_2SO_4 and $\text{K}_2\text{Cr}_2\text{O}_7$ gives di-iodo quinone (*q v*) — B'Cl Decomposed by water

iodo AMIDO THYMOL
 $\text{C}_9\text{HIMEPr}(\text{OH})(\text{NH})$ [6 5 2 1 4] From the oxim of iodo thymoquinone by reduction with SnCl_2 (Kehrmann, *J pr* [2] 39, 392) Its stannous chloride forms large colourless prisms

iodo AMIDO-TOLUENE SULPHONIC ACID
 $\text{C}_6\text{H}_4\text{MeI}(\text{NH}_2)\text{SO}_3\text{H}$ [1 4 2 5] Formed from the corresponding nitro toluidine sulphonic acid by diazotisation and treatment of the product with conc HIAq at 135° (Foth, *A* 230, 308) Slender silky needles (from water) V sl sol cold water

iodo AMYL ALCOHOL $\text{C}_5\text{H}_{11}\text{IO}$? Amylene glycol iodhydrin Formed by shaking un-amylene with iodine, water, and HgO (Lippmann, *Z* 1867, 17, 4 *Suppl* 5, 124) Heavy oil, decomposed by distillation

iodo AMYLIDENE ANILINE
 $\text{C}_6\text{H}_4\text{ICH}=\text{C}_6\text{H}_5$ Formed by heating iodo iso valeric aldehyde with aniline (Chautard, *A Ch* [6] 16, 168) Yellow prismatic needles or rectangular tables Decomposed by heat V sol alcohol, sol water and ether, v sl sol benzene and chloroform With HCl it forms an uncrystallisable salt

o IODO ANILINE $\text{C}_6\text{H}_4\text{IN}$ *i.e.* $\text{C}_6\text{H}_3\text{I}(\text{NH}_2)$ [1 2] Mol w 219 [56 5°] Formed by heating at 100° a mixture of o-iodo nitro benzene (25 pts) with ferrous sulphate (250 pts) and a moderate excess of dilute ammonia The product is extracted with ether, the extract distilled with steam, the product dissolved in dilute H_2SO_4 , freed from iodo nitro benzene by shaking with ether, ppd by ammonia and the iodo aniline again distilled with steam (Korner & Wender, *G* 17, 486) Long silky needles, with an odour resembling pyridine Sl sol hot water, v sol other solvents Exhibits an alkaline reaction. Turns brown on exposure to air and light Decomposes when heated, evolving iodine Iodine converts it into di-iodo aniline [96°]

Salts — B'Cl aq small prisms or cubes, turning opaque on exposure, with loss of water of crystallisation — B' , $(\text{H}_2\text{SO}_4)_2$, silky needles, m sol water — Nitrate small four sided tables

Acetyl derivative $\text{C}_6\text{H}_3\text{INHAc}$ [110°] Prisms or hexagonal tables, m sol hot water, v sol alcohol

m-Iodo-aniline $\text{C}_6\text{H}_4(\text{NH}_2)$ [1 3] [27°] Formed by reducing m-iodo nitro-benzene (Gress, *Z* 1866, 218) Silvery plates

Acetyl derivative $\text{C}_6\text{H}_4(\text{NHAc})$ [119 5°]

Glistening needles; more stable than the *o*-isomeride (Körner & Wender, *G* 17, 486)

p-Iodo-aniline $C_6H_4I(NH_2)$ [14] [83°]
Formed by reducing *p* iodo-nitro-benzene [172°] (Grüss, *C* J 20, 85) Formed also by adding iodine (3 pts) to aniline (2 pts) and mixing the solution with aqueous HCl (S G 111) when *p*-iodo aniline hydrochloride is ppt (Hofmann, *A* 67, 64) Prisms or needles, heavier than water Has no action on litmus Sl sol cold water, v sol other solvents Bromine converts it into tri-bromo-aniline — B'HCl thin laminae or needles (from hot water), sl sol cold water, almost insol HClAq, sol alcohol, insol ether — $B'_2H_4PtCl_6$, orange pp — $B'_2H_4C_2O_4$, long needles, sl sol water and alcohol, insol ether — $B'_2H_4SO_4$, scales

Acetyl derivative $C_6H_4I(NHAc)$ [183°]
S (alcohol of 95 p c) 6.4 at 20.5° Small glistening tables or trimetric prisms (K & W) Formed by dissolving acetanilide in glacial acetic acid, and passing in vapour of iodine chloride, the yield being 85 p c (Michael & Norton, *Am* 1, 255)

Benzoyl derivative $C_6H_4I(NHBz)$ [180°]
Long needles (Hubner, *B* 10, 1717) An isomeride [210°] is formed from benzanilide and ICl

Di iodo aniline $C_6H_3I_2NH_2$ [4 2 1] [96°]
Formed by the action of iodine on phenylated 'white precipitate' NHPH HgCl (Rudolph, *B* 11, 78) Formed also by passing ICl (2 mols) into a solution of aniline in HOAc (Michael & Norton, *Am* 1, 255, *B* 11, 109) Needles Sl sol boiling water and ligroin, v sol ether, chloroform, CS₂, acetic ether, and hot alcohol Volatile with steam It is slightly basic, but its hydrochloride is decomposed by cold water — B'HCl: long white needles, decomposed at 50°. — $B'_2H_4PtCl_6$ — B'_2HNO_3 — $B'_2(H_2SO_4)_2$

Benzoyl derivative $C_6H_3I_2NHBz$ [181°]
Slender needles (Rudolph)

Tri-iodo-aniline $C_6H_2I_3(NH_2)$ [6 4 2 1] [185.5°]
Prepared by the action of ICl (3 mols) on a solution of aniline in HClAq (Michael & Norton, *Am* 1, 255) Long white needles, sol CS₂ and acetic ether, insol water

IODO-ANISIC ACID *v* *Methyl derivative of Iodo oxy-benzoic acid*

IODO-BENZENE C_6H_4I *Phenyl iodide*
Mol w 204 (188°) S G § 18606, $\frac{15.2}{1}$ 18380 (Young, *C* J 55, 486), $\frac{2}{1}$ 18578, $\frac{1}{2}$ 18403, $\frac{3}{2}$ 18321 S V 130 55 (R Schiff, *B* 19, 564) $n_D^{20} = 1.6189$ (Seubert, *B* 22, 2520).

Formation — 1 By treating phenol with iodine and phosphorus The yield is bad (Williamson & Scruggam, *C* J 18, 244) — 2 By the action of ICl on sodium benzoate (Schützenberger, *C. R* 52, 963) — 3 By heating benzene for some time with iodic acid (Peltzer, *A* 186, 194) — 4 By the action of HI on diazobenzene salts (Grüss, *J* 1866, 447) — 5 By heating benzene (20 g) with iodine (15 g) and iodic acid (10 g), at 220° (Kekulé, *A* 187, 157) — 6 From benzene, iodine and FeCl₃ (Lothar Meyer, *A* 281, 195) — 7 By the action of excess of iodine on phenyl hydrazine (E v Meyer, *J. pr.* [2] 86, 115)

Preparation — By allowing chloride of iodine to drop slowly into a large excess of benzene

containing a small quantity of aluminium chloride (Greene, *C. R* 9f, 40)

Properties — Colourless oil, insol water Solidifies when cooled by solid CO₂. Easily reduced by sodium amalgam to benzene Aqueous HIAq at 250° reduces it to benzene Not affected by solid KOH at 250°, nor by alcoholic KOH or NH₃ (Kekulé)

Reactions — 1 H₂SO at 100° forms a mixture of iodo-benzene sulphonic acid, di iodo-benzene, and benzene sulphonic acid, in proportions varying with proportions of materials employed, strength of the acid, temperature, and duration of the experiment (Neumann, *A* 241, 47) — 2 *Silver nitrate* does not act below 135°, but between 140° and 150° reaction takes place forming tri-nitro phenol, AgI, and metallic silver (Geuther, *A* 245, 99) — 3 By heating with *aluminium chloride* there is formed benzoene, di-iodo benzenes, HCl, and iodine (Dumreicher, *B* 15, 1868)

Dichloride $C_6H_4I_2Cl_2$. Formed by passing chlorine into liquid iodobenzene Formed also by passing chlorine into a solution of iodobenzene (5 g) in chloroform (15 g) (Willgerodt, *J. pr* [2] 83, 154) Begins to decompose at 80°, and at 120° it is all broken up into Cl₂ and C₆H₅I It may be kept in glass bottles, but if placed over H₂SO, it gives off chlorine It is decomposed by solution in alcohol, but it may be crystallised from chloroform as yellow needles It dissolves in benzene, glacial acetic acid, light petroleum, CS₂, and ether As a reagent it displaces iodine by chlorine, turning KI, PbI₂, &c, into KCl PbCl₂, &c, with separation of iodine May therefore be used as a test for iodides It also converts alcoholic iodides (e.g MeI) into chlorides It is hardly attacked by cold aqueous NH₃ or NaOH

o Di iodo benzene $C_6H_3I_2$ [1 2] [27°] (287°)

Preparation — Iodo aniline (10 g) is dissolved in hot water (70 g) containing H₂SO₄ (9 g), KNO₃ (4.5 g) dissolved in a little water is added, and then an excess of solution of KI in aqueous HI (S G 11) After standing a few hours the oil that has separated is washed with KOHAq and distilled with steam (Körner & Wender, *G* 17, 486, cf Körner, *G* 4, 305) Long prisms or hexagonal tables Volatile with steam Sl sol water, sol alcohol

m Di iodo benzene $C_6H_3I_2$ [1 3] [40°] (K), [37°] (R) (285°) From *m* iodo aniline by displacing NH₂ by I (Körner) Also from di iodo aniline by elimination of NH₂ (Rudolph) Trimetric tables (from ether-alcohol)

p-Di-iodo-benzene $C_6H_3I_2$ [1 4] [127°] (Kekulé), [129°] (Körner) A product of the action of iodine chloride on NaOBz (Schützenberger) and of iodine and iodic acid on benzene (Kekulé) Formed also from *p* iodo-aniline by the diazo-reaction (Kekulé, *Z* 1866, 688). Nacreous laminae Readily sublimed

Tri-iodo-benzene $C_6H_2I_3$ [1 2 4] Mol w 456. [76°]. A product of the action of iodine and iodic acid on benzene (Kekulé). Small needles May be sublimed

IODO-BENZENE-AZOXY-COMPOUNDS *v* **AZOXY-COMPOUNDS.**

IODO-BENZENE *o*-SULPHONIC ACID
 $C_6H_3I_2SO_3H$ [1:2] From *o*-amido-benzene sulphonic acid by the diazo-reaction (Bahlmann, *A*.

186, 825) — KA' :aq: crystals, sl. sol. water — BA'_2 , needles, sl. sol. cold, v. sol. hot, water
Chloride $\text{C}_6\text{H}_4\text{I SO}_2\text{Cl}$ [51°] Thick prisms (from ether)

Amide $\text{C}_6\text{H}_4\text{I SO}_2\text{NH}_2$. [170°]. White laminae, sl. sol. water

Iodo-benzene p sulphonic acid $\text{C}_6\text{H}_4\text{ISO}_3\text{H}$ [14] From iodo benzene and fuming H_2SO_4 (Körner a Paterno, *G* 2, 448) Formed also from amido benzene *p* sulphonic acid by displacing NH_2 by *I* through the diazo-reaction (Lenz, *B* 10, 1135) Deliquescent needles — $\text{NH}_4\text{A}'$. minute needles — KA' needles — CaA'_2 — BaA'_2 . minute plates, sl. sol. water — PbA'_2 .

Chloride $\text{C}_6\text{H}_4\text{ISO}_2\text{Cl}$ [87°] Laminae

Amide $\text{C}_6\text{H}_4\text{I SO}_2\text{NH}_2$. [183°]. Crystalline powder, sl. sol. water, v. so. alcohol

o IODO-BENZOIC ACID $\text{C}_6\text{H}_4\text{I CO}_2\text{H}$ [157°]

Formation — 1 From *o* amido benzoic acid by the diazo reaction (Griess, *C J* 24, 702) — 2 By oxidising *o* iodo toluene with dilute HNO_3 (Kekulé, *B* 7, 1007) — 3 From *m* iodo nitro benzene and alcoholic KCy at 200° (Richter, *B* 4, 554)

Properties — Long needles, may be readily sublimed. Sl. sol. hot water, v. e. sol. ether and alcohol. Gives salicylic acid when fused with potash

Salts — CaA'_2 , 2aq — BaA'_2 , 6aq

m Iodo benzoic acid $\text{C}_6\text{H}_4\text{I CO}_2\text{H}$ [187°]

Formation — 1 From *m* amido benzoic acid by the diazo reaction (Griess, *A* 113, 334, 117, 1, Cunze a Hübner, *A* 135, 108, Grothe, *J pr* [2] 18, 324) — 2 By heating benzoic acid (1 pt) with KIO_3 (2 pts) and dilute H_2SO_4 (Peltzer, *A* 136, 201) — 3 By oxidising *o* iodo toluene with chromic acid mixture (Körner, *Z* [2] 5, 637) — 4 By heating dry silver benzoate with iodine at 150°–180° (Birnbäum a Reinherz, *B* 15, 456)

Properties — Needles, sl. sol. water, v. sol. alcohol. May be sublimed. Gives *p* oxy benzoic acid on oxidation. Ammonia forms amido benzoic acid

Salts — NaA' , aq — MgA'_2 , 4aq — CaA'_2 , 2aq scales — CaA'_2 , nodules — BaA'_2 , 4aq needles, sol. alcohol. — MgA'_2 , 4aq

Ethyl ether EtA' Oil

Nitrile $\text{C}_6\text{H}_4\text{I CN}$ [41°] From *m*-amido benzonitrile by the diazo reaction. Needles

p Iodo-benzoic acid $\text{C}_6\text{H}_4\text{I CO}_2\text{H}$ [266°] (Beran, *B* 18, 137, Klingel, *B* 18, 2693) Formed by oxidation with chromic acid mixture from *p* ic lo-toluene (Körner, *Z* [2] 5, 327), from *p* iodo-phenyl acetic acid (Jackson a Mabery, *Am* 2, 253), or from *p* iodo acetophenone (Klingel) Nacreous scales (from alcohol) Nearly insol. boiling water. Converted by potash fusion into *p* oxy benzoic acid

Salts (Glassner, *B* 8, 562) — NaA' , aq colourless needles, v. sol. water — KA' — BaA'_2 , 1½aq. long trimetric plates — CaA' , aq — SrA'_2 , aq nacreous laminae. — ZnA'_2 , 4aq cubes

Methyl ether MeA' [114°] Long needles (Schmidt a Schultz, *A*, 207, 883)

Ethyl ether EtA' Oil

o IODO-BENZOIC ALDEHYDE $\text{C}_6\text{H}_4\text{I CHO}$ [87°] Formed from *o*-nitro cinnamic acid by successive conversion into amido-, diazo-, and iodo cinnamic acid, and oxidation of the latter with KMnO_4 (Stuart, *C J*, 53, 140).

p-Iodo-benzoic aldehyde $\text{C}_6\text{H}_4\text{I CHO}$. [73°]. Needles (Jackson a. White, *B* 11, 1042, *P Am A* 15, 269)

p-IODO-BENZYL ALCOHOL $\text{C}_6\text{H}_4\text{I CH}_2\text{OH}$ [72°] Prepared by heating *p*- iodo benzyl bromide with NaOAc and aqueous NH_3 at 160° Formed also by heating *p* iodo benzyl bromide with water for a long time (Jackson, *P Am A* 13, 202, Jackson a. Mabery, *Am* 2, 251, *B* 11, 56) Silky scales (from alcohol or CS_2) or long needles (from water) Sl. sol. cold water, v. sol. alcohol, ether, benzene, and CS_2 .

o IODO-BENZYLAMINE $\text{C}_6\text{H}_4\text{I NH}_2$

[21] $\text{C}_6\text{H}_4\text{I CH}_2\text{NH}_2$ From *o* iodo benzyl bromide and alcoholic NH_3 (Mabery a Robinson, *Am* 4, 103) Liquid. Absorbs CO from the air — $\text{B}'\text{H}_2\text{PtCl}_6$ minute yellow prisms

p Iodo benzylamine [41] $\text{C}_6\text{H}_4\text{I CH}_2\text{NH}_2$

Formed by heating *p* iodo benzyl bromide with alcoholic NH_3 at 120° (Jackson a. Mabery, *Am* 2, 257) Oil. Absorbs CO from the air forming a carbonate [113°] — $\text{B}'\text{HCl}$ slender white needles [240°], sol. water and alcohol, sl. sol. ether — $\text{B}'\text{H}_2\text{PtCl}_6$

Di-p-iodo-di benzyl amine $(\text{C}_6\text{H}_4\text{I CH}_2)_2\text{NH}$

[76°] Formed, together with tri *p* iodo tri benzylamine, by boiling *p* iodo benzyl bromide with alcoholic NH_3 (Jackson a. Mabery, *Am* 2, 256, *B* 11, 58, *P Am A* 13, 209) White needles, insol. water, v. sol. hot alcohol, ether, benzene, and CS_2

Salts — $\text{B}'\text{HCl}$ thick white plates, sol. CS_2 and HOAc , sl. sol. alcohol and benzene — $\text{B}'\text{HBr}$ thick pearly prisms, insol. water, sl. sol. alcohol sol. ether, benzene, and CS_2 — $\text{B}'\text{H}_2\text{PtCl}_6$ minute yellow needles, almost insol. water and alcohol — $\text{B}'\text{H}_2\text{CO}$, [113°] Crystalline

Tri-*p* iodo-tri-benzyl-amine $(\text{C}_6\text{H}_4\text{I CH}_2)_3\text{N}$

[115°] Formed as above (J. a. M.) White needles (from ether), v. sl. sol. hot alcohol, v. sol. ether, benzene, and CS_2 . — $\text{B}'\text{H}_2\text{PtCl}_6$ yellow needles, nearly insol. water and alcohol

o IODO BENZYL BROMIDE $\text{C}_6\text{H}_4\text{I CH}_2\text{Br}$

[53°] Prepared by dropping bromine into *o* iodo toluene heated to 190°–200° (Mabery a Robinson, *Am* 4, 102, *P Am A* 17, 103) Thick flattened prisms (from ligroin), v. sol. ether, hot alcohol, benzene, CS_2 , and chloroform, insol. water. Its vapour is very pungent. Gives *o* iodo benzoic acid on oxidation with dilute HNO_3 .

p Iodo benzyl bromide $\text{C}_6\text{H}_4\text{I CH}_2\text{Br}$ [79°]

Prepared by heating *p* iodo toluene in bromine vapour at 115°–150° (Jackson, *Am* 1, 93) Straw coloured needles, somewhat pungent. Insol. water and cold alcohol, sol. hot alcohol, v. sol. ether. Hardly attacked by CrO_3 .

IODO-BENZYL CYANIDE *o* Nitrile of Iodo-benzyl-acetic acid

o IODO BENZYLIDENE-MALONIC ACID

$\text{C}_6\text{H}_4\text{IO}$, *o* $\text{C}_6\text{H}_4\text{I CH}(\text{CO}_2\text{H})_2$ [204°] Formed by heating equal weights of malonic acid and iodo benzoic aldehyde for several hours at 100° with half their weight of HOAc (Stuart, *C J* 53, 142) Decomposed on melting into CO_2 and *o*-iodo cinnamic acid

o-IODO-BENZYL-MALONIC ETHER

$\text{C}_6\text{H}_4\text{CH}_2\text{Cl}(\text{CO}_2\text{Et})_2$ From sodium benzyl malonic ether and iodine (Bischoff a. Hausdöfler, *A*, 239, 110). Oil. Decomposes on hydrolysis

into benzoic aldehyde, alcohol, acetic acid, and CO_2 .

***p*-IODO BENZYL SULPHOCYANIDE**

$\text{C}_6\text{H}_4\text{I} \cdot \text{SCy}$ [40°] Formed by boiling *p* iodo-benzyl bromide with an alcoholic solution of potassium sulphocyanide (Jackson, *P Am A* 18, 207, *B* 11, 58) Long white plates (from alcohol) *M* sol hot alcohol, *v* sol ether, benzene, CS_2 , and HOAc

IODO BETORCIN $\text{C}_8\text{HIME}(\text{OH})_2$ [93°]

Formed by the action of PbO and *I* (2 pts) on an ethereal solution (50 pts) of betorcin (1 pt) Crystallised from light petroleum (Stenhouse & Groves, *C J* 37, 404) *V* sol ether, CS_2 , and benzene

IODO BROMO-*v* BROMO IODO-

IODO BUTANE *v* BUTYL IODIDES

Di iodo butane $\text{C}_4\text{H}_2\text{I}_2$ *se*

$\text{CH}_3\text{CH}_2\text{CHI}_2\text{CH}_3$ (116° *in vacuo*) *SG* 2 291 From the corresponding di oxy butane and *HI* (Wurtz, *Bl* [2] 41, 362)

***p* IODO-ISOBUTYL BENZENE $\text{C}_6\text{H}_5(\text{C}_4\text{H}_9)\text{I}$**

(256° *cor*) Formed by the action of *HI* on the diazo compound from *p* amido phenyl butane (Pahl, *B* 17, 1232) Colourless oil By HNO_3 , it is oxidised to *p* iodo benzoic acid

IODO BUTYLENE $\text{C}_4\text{H}_6\text{I}$ Crotyl iodide

(132°) From tri oxy butane (butenyl glycerin), iodine, and phosphorus (Lieben & Ziesel, *M* 1, 836) Pungent liquid Combines with mercury forming an unstable crystalline compound

IODO-ISOBUTYL TOLUENE

$\text{C}_6\text{H}_5(\text{CH}_3)(\text{C}_4\text{H}_9)\text{I}$ [136] [*c* 35°] (264°) Formed by diazotising amido tolyl isobutane and treating the product with *HI* (Effront, *B* 17, 2325) Long white needles *V* sol alcohol and ether On oxidation with HNO_3 at 200° it gives nitro tolyl isobutyric acid

a* IODO *n* BUTYRIC ACID $\text{C}_4\text{H}_9\text{IO}_2$ *se

$\text{CH}_3\text{CH}_2\text{CHI CO}_2\text{H}$ [110°] (Fittig, *B* 9, 1194) From *a* crotonic acid and fuming *HI* at 100° (Hemilian, *A* 174, 324, *v infia*) Monoclinic crystals (Haushofer, *Z K* 6, 135)

Ethyl ether EtA' (191°) Formed by boiling *a* bromo butyric ether with alcoholic *KI* (Hell, *B* 6, 29)

***β* Iodo-butyric acid $\text{CH}_3\text{CHI CH}_2\text{CO}_2\text{H}$**

Formed, in small quantity, in the preparation of the preceding Liquid

According to Michael and Freer (*J pr* [2] 40, 95) *HI* unites with solid crotonic acid forming, contrary to the statement of Hemilian, only *β* iodo-butyric acid, of low melting point The same acid is formed from liquid crotonic acid and *HI* Boiling water converts it into *β* oxy-butyric acid Hot NaOH aq gives solid crotonic acid

***γ*-Iodo-butyric acid $\text{CH}_3\text{I CH}_2\text{CH}_2\text{CO}_2\text{H}$**

[41°] From the lactone of *γ* oxy butyric acid and *HI* (Henry, *C R* 102, 868, A Saytzeff, *B* 14, 2826) Colourless plates, which become yellow in sunlight *Sl* sol warm water (difference from *β* isomeride), *v* sol. methyl alcohol, ether, and CS_2 .

Methyl ether MeA' (199°) *SG* 1 666

Oil, with pleasant odour

Iodo-isobutyric acid $(\text{CH}_3)_2\text{CI CO}_2\text{H}$ (?)

[36°] From methacrylic acid and fuming *HI* at 0° (Fittig & Paul, *A* 188, 58, 200, 67) Tables (from CS_2) or large prisms (from conc. HIA aq) *Sl* sol. water.

Di iodo isobutyric acid $\text{O}_2\text{H}_2\text{IO}_2$ [127°].

Formed by treating tri oxy isobutyric acid with *HI* and *P* and extracting the product with ether (E Fischer & Tafel, *B* 22, 108) Long needles, *v* *e* sol alcohol and ether

IODO ISOBUTYRIC ALDEHYDE

$(\text{CH}_3)_2\text{CI CH CO H}$ or $(\text{CH}_3)_2\text{CI CO H}$ *SG* 2 229

Preparation—By treating isobutyric aldehyde (22.5 cc) dissolved in 40 cc of alcohol, with iodine (25 g) and iodic acid (10 g) It is very difficult to obtain pure, 130 g of the crude body yielding not more than 1 g sufficiently pure for analysis Reduced silver removes the excess of iodine with the least loss of substance (Chautard, *A Ch* [6] 14, 160)

Properties—Heavy liquid, colourless when pure Its vapour is, like its homologues, exceedingly irritating It is completely decomposed at 100°, and cannot be distilled even *in vacuo* Forms a crystalline compound with NaHSO_4 Is rapidly resinified by solutions of alkalis or mineral acids Combines with aniline, with elimination of water, giving a di amine $\text{Ag}(\text{C}_4\text{H}_9\text{O}_2)$ at 100° yields isobutyl acetate (114°) AgCN and AgSCN yield the corresponding cyano and sulphocyno derivatives

IODO CAMPHOR *v* CAMPHOR

IODO CAPROIC ACID *v* IODO HEXOIC ACID

IODO-CAPRYL-BENZENE *v* IODO OCTYL-

BENZENE

IODO CARBOSTYRIL *v* IODO OXY-QUINOLINE

IODO CHELIDONIC ACID *v* CHELIDONIC ACID

IODO CHRYSIN *v* CHRYSIN

o* IODO CINNAMIC ACID $\text{C}_6\text{H}_4\text{IO}_2$ *se

$\text{C}_6\text{H}_4\text{I CH CO}_2\text{H}$ [214°] (*G a H*), [207°] (*S*) Formed by boiling *o* diazo cinnamic acid with aqueous *HI* (Gabriel & Herzberg, *B* 14, 2037) Formed also by heating *o* iodo benzyl idene malonic acid to its melting point (Stuart, *C J* 53, 142) Crystals (from dilute alcohol)

***m*-Iodo-cinnamic acid $\text{C}_6\text{H}_4\text{I C}_6\text{H}_4\text{CO}_2\text{H}$**

[182°] Formed by boiling *m* diazo cinnamic acid with *HI* (*G a H*) Sol benzene, petroleum ether, and hot alcohol, *sl* sol water

***p* Iodo-cinnamic acid $\text{C}_6\text{H}_4\text{I C}_6\text{H}_4\text{CO}_2\text{H}$**

[*c* 255°] Formed by boiling *p* diazo cinnamic acid with *HI* (Gabriel & Herzberg, *B* 16, 2040) Crystalline mass

IODO CODEINE *v* CODEINE

IODO-COMPOUNDS Organic compounds containing iodine attached to carbon

Formation—1 Unlike chlorine an 'bromine, iodine is not capable of directly displacing hydrogen, inasmuch as the *HI* produced would cause a reverse reaction But if iodic acid, mercuric oxide, or some other substance capable of removing *HI* be present, the substitution may take place (Kekulé, *A* 131, 281) In the case of aniline, the free *HI* combines with excess of aniline and thus iodo aniline may be formed Mercuric oxide will not induce the iodination of fatty compounds, but is especially useful in the case of phenols and oxy acids (Wesselsky, *A* 174, 99). The operation is performed in boiling alcoholic solution, and an intermediate body appears to be mercurioiodate (Lippmann, *B* 7, 1773) Aromatic hydrocarbons may be iodated by heating with iodine and dry FeCl_3 (L Meyer, *A* 231, 195) — 2 By the action of *HI* on hydroxylic compounds,

The alkyl iodides may be prepared in this way by the action of HI or, better, of iodine and phosphorus on the corresponding alcohols, at 100°. The polyhydric alcohols give rise, in this way, to secondary alkyl iodides, the iodine displacing hydrogen attached to a penultimate atom of carbon thus glycerin gives isopropyl iodide. Iodides of acid radicles are formed by the action of iodide of phosphorus on the dry alkaline salts (Canours, *A* 104, 111) — 3 By the union of HI with unsaturated compounds. This combination takes place more readily than in the case of HCl and HBr. The iodine attaches itself to that one of the involved atoms of carbon that is combined with the smaller amount of hydrogen, e.g. $\text{CH}_3\text{CH}=\text{CH}_2 + \text{HI} = \text{CH}_3\text{CHI}-\text{CH}_3$. 4 From aromatic amido compounds by the diazo reaction. This may be performed by heating the diazo compounds with HIAq, or with aqueous KI, e.g. $\text{C}_6\text{H}_5\text{N}_2\text{SO}_3\text{H} + \text{KI} = \text{C}_6\text{H}_5\text{I} + \text{N}_2 + \text{KHSO}_4$. Also by Sandmeyer's reaction which consists in boiling the diazo compound with cuprous iodide, or Diazo compounds — 5 By gradually adding HNO_3 to a hot solution of the amine in HIAq (Losanitsch, *B* 18, 39) — 6 By displacing Cl or Br by I by treatment with a metallic iodide. The elements K, Mg, Ca, Sr, Ba, Al, Mn, and Co prefer chlorine and bromine to iodine and hence the iodides of these metals when heated with chloro or bromo compounds produce iodo compounds (Köhnlcin, *A* 225, 194) Thus propyl chloride is converted into propyl iodide by CaI_2 , SrI_2 , MnI_2 , and CoI_2 , while it is but slightly affected by NiI_2 and FeI_2 , is not affected by SnI_2 , and is wholly decomposed by PI_3 . The conversion of benzyl chloride into benzyl iodide is partially effected by BaI_2 at 15°, by ZnI_2 at 10°, by CdI_2 at 100°, and by PbI_2 at 160°. On the other hand isobutyl chloride is not converted into iodide at 70° by BaI_2 , by ZnI_2 or by CdI_2 , while CdI_2 at 135° decomposes it. The substitution of Cl in chloroacetic acid by I is partly effected by CdI_2 or TI_2 at 100°, and may be effected by BaI_2 or ZnI_2 at 100° (Brix *A* 225, 166). Potassium iodide is a very convenient reagent for the purpose (Perkin & Duppa, *A* 112, 125) but cannot be always depended upon, for though it displaces Cl by I in the case of epichlorhydrin, chloro lactic acid, dichlorhydrin, and mono- and di-chloro acetone, it does not act on di-chlorinated ether, and it decomposes chloral into chloroform and CO_2 . Calcium iodide $\text{CaI}_2 \cdot 3\text{aq}$ is also an excellent reagent for converting chloro and bromo compounds into the corresponding iodo-derivatives (Spindler, *A* 231, 257). Thus it converts $\text{CH}_3\text{CH}_2\text{CH}_2\text{Br}$ into ethylene iodide, and $\text{CH}_3\text{CH}_2\text{CH}_2\text{Br}$ into CH_3CHI , but it fails with $\text{CH}_3\text{CH}_2\text{CH}_2\text{Cl}$, with $\text{CHCl}_2\text{CH}_2\text{Cl}$, with $\text{CCl}_2\text{CH}_2\text{Cl}$, with CCl_3 , with chloro benzene, and with chloral. Dry CaI_2 requires a higher temperature (120°) before it reacts, and this decomposes many of the iodo compounds that should be formed — 7 Iodine chloride also acts as an iodating substance, especially upon aromatic amines. Thus it converts aniline (dissolved in HOAc) into di-iodo aniline (when 2 mols ICl are used) and tri-iodo-aniline (when 3 mols ICl are used). It converts acetanilide into acetyl p-iodo aniline, m nitro aniline into di-iodo m nitro-aniline, p-nitro aniline chiefly into iodo-p-nitro-aniline, and p-toluidine into di-iodo-p-toluidine: but it

does not act on acetyl p toluidine (*B* 11, 107) — 8 By heating chloro- compounds with fuming HIAq (Lieben, *Z* 1868, 712) — 9 Nitrogen iodide, acting on dilute alcoholic solutions of the potassium derivatives of phenols, forms iodo phenols and ammonia (Willgerodt, *J pr* [2] 37, 446).

Reactions — 1 The displacement of iodine by chlorine or bromine may be effected by heating with the chloride or bromide of Hg, Cu, Ag, Sn, Pb, As, or Sb (v **Chloro compounds and Bromo compounds**) — 2 Chlorine and bromine displace iodine directly — 3 Sodium frequently removes iodine with ease, e.g. $2\text{C}_6\text{H}_5\text{I} + \text{Na}_2 = \text{C}_6\text{H}_5 + 2\text{NaI}$. In like manner (by what is known as Fittig's reaction) $\text{C}_6\text{H}_5\text{I} + \text{C}_6\text{H}_5\text{I} + \text{Na}_2 = \text{C}_6\text{H}_5\text{C}_6\text{H}_5 + 2\text{NaI}$. 4 Water readily decomposes tertiary alkyl iodides, forming HI and a tertiary alcohol. Methyl and ethyl alcohol at 100° act in like manner, forming a tertiary alcohol and MeI or EtI — 5 Silver obtained by reduction sometimes removes iodine e.g. $2\text{CH}_3\text{I} + \text{CH}_3\text{CO}_2\text{H} + \text{Ag}_2 = 2\text{AgI} + \text{CO}_2\text{H} + \text{CH}_3\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$.

Some aromatic iodo compounds can take up chlorine, e.g. PhI gives PhICl_2 (Willgerodt, *J pr* [2] 33, 154), $\text{C}_6\text{H}_5\text{BrI}$ gives $\text{C}_6\text{H}_5\text{BrICl}_2$, while $\text{C}_6\text{H}_5\text{BrI}$ gives $\text{C}_6\text{H}_5\text{BrICl}_2$, and $\text{C}_6\text{H}_5(\text{NO}_2)\text{I}$ gives $\text{C}_6\text{H}_5(\text{NO})\text{ICl}_2$. $\text{C}_6\text{H}_5(\text{NO})\text{I}$ has no action.

iodo m CRESOL $\text{C}_6\text{H}_4\text{MeI}(\text{OH})$ [1 x 3] Oil. Formed by adding iodine to a solution of m-cresol in ammonia and alcohol (Willgerodt & Kornblum, *J pr* [2] 39, 289).

Iodo p cresol $\text{C}_6\text{H}_4\text{MeI}(\text{OH})$ [1 3 4] Formed by the action of dry iodine on sodium m-cresol suspended in CS (Schall & Dralle, *B* 17, 2533). Liquid. Volatile with steam.

Methyl ether $\text{C}_6\text{H}_4\text{MeI}(\text{OMe})$ (238°), oil. **Di iodo o cresol** $\text{C}_6\text{H}_3\text{MeI}_2(\text{OH})$ [1 3 4 2] [70°] Formed by the action of iodide of nitrogen upon the sodium compound of o-cresol (Willgerodt *J pr* [2] 37, 448, 39, 289).

Acetyl derivative $\text{C}_6\text{H}_3\text{MeI}_2(\text{OAc})$ [56°] Tables.

Picrate. [204°] Yellow crystalline aggregates.

Di iodo m cresol $\text{C}_6\text{H}_3\text{MeI}_2(\text{OH})$ [76°] Formed together with iodo m cresol (W & K). Long needles, sol. usual menstrua.

Di iodo p cresol $\text{C}_6\text{H}_3\text{MeI}_2(\text{OH})$ [1 3 5 4] [61°] Formed together with the preceding (Schall & Dralle, *B* 17, 2534). White tables. Easily soluble in alcohol, sparingly in water and ligroin. Volatile with steam.

Acetyl derivative $\text{C}_6\text{H}_3\text{MeI}_2(\text{OAc})$ [62°], white tables.

Benzoyl derivative $\text{C}_6\text{H}_3\text{MeI}_2(\text{OBz})$ [130°], glimmering white prisms.

Ethyl ether $\text{C}_6\text{H}_3\text{MeI}_2(\text{OEt})$ [77°] White solid sol. organic solvents (Willgerodt & Kornblum, *J pr* [2] 39, 289).

iodo CRESOL SULPHONIC ACID $\text{C}_6\text{H}_4\text{MeI}(\text{OH})\text{SO}_3\text{H}$ [3 1 2 5] [155°] Formed together with an isomeride, by the action of iodine on the potassium salt of o-cresol sulphonic acid (Kehrmann, *J pr* [2] 37, 338). Colourless plates (containing 3aq). Converted by nitric acid into dinitro cresol [86°] Chromic acid forms iodo toluquinone [115°].

Salts — A'K fine needles — A', Ba 4aq. **Di-iodo m cresol sulphonic acid** $\text{C}_6\text{H}_3\text{MeI}_2(\text{OH})(\text{SO}_3\text{H})$ [3 6 2 1 4] [70°] From potassium m-cresol sulphionate by treatment with

Iodine (Kehrmann, *J pr* [2] 39, 392) Small needles Oxidised by CrO_3 to di-iodo-toluquinone

IODO- ψ -CUMENE $\text{C}_9\text{H}_7\text{IO}_2$ [1245] *Iodo-tri-methyl-benzene* [37⁵] (258^o) Formed by decomposing ψ -cumene diazopiperidine with HIAq (SG 173) (Wallach & Heusler, A 243, 233) Formed also from ψ -cumidine by diazotising and heating the product, dissolved in H_2SO_4 with KI (Kurzel, B 22, 1586) Scales Treatment with H_2SO_4 forms two isomeric di-iodo ψ -cumene sulphonic acids ψ -cumene sulphonic acid and iodo ψ -cumene sulphonic acid One of the di-iodo ψ -cumenes melts at 74^o, the other is an oil

IODO ψ -CUMENE SULPHONIC ACID

$\text{C}_9\text{H}_6\text{IO}_2\text{SO}_3\text{H}$ Formed as above Scales, m sol water

Salts — NaA'aq plates — BaA' aq needles

IODO CYANETHINE v **CYANTHINE**

IODO ETHANE v **ETHYL IODIDE**

Di-iodo-ethane v **ETHYLENE IODIDE** and **ETHYLDENE IODIDE**

Tri-iodo-ethane $\text{C}_2\text{H}_3\text{I}_3$, ρ CH_3Cl , [95^o]

Formed by the action of aluminium iodide upon CH_3CCl_3 (De Boissieu, B [2] 49, 16) Yellow octahedra V e sol CS, benzene, and ether, v sol petroleum ether, m sol alcohol Smells faintly of iodoform

IODO-ETHYL ALCOHOL v **GLYCOLIODHYDRIN**
 β -IODO ETHYL AMINE $\text{CH}_3\text{CH}_2\text{NH}_2$

Hydriodide B'HI [194⁵] From vinylamine and conc HIAq (Gabriel, B 21, 1049) Trim⁴ crystals (from hot alcohol) V sol water When treated with KOH it gives a liquid, soluble in water, with a disagreeable odour

Picrate $\text{B}'\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH} \frac{1}{2}\text{aq}$ [c 105^o] (hydrated), [131⁵] (anhydrous) Short compact yellow prisms

Di-iodo ethyl-amine EtNI_2 , v *Ethyl di-iodo amine*, vol 11 p 474

Di-iodo ETHYL BENZENE $\text{C}_8\text{H}_7\text{I}_2$, ρ $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{I}$ *Styrene di iodide* From styrene and a concentrated solution of iodine in KIAq (Berthelot, B 6, 295, 7, 277) Crystals, v sol ether Rapidly decomposes into iodine and metastyrene

IODO-ETHYLENE $\text{C}_2\text{H}_2\text{I}_2$, ρ CH_2CHI *Vinyl iodide* (56^o) SG 2 208 Formed by distilling ethylene iodide with conc alcoholic potash, the receiver being kept very cool, and the distillate finally mixed with water (Regnault, A 15, 69, E Kopp, C R 18, 871) Also from ethyldene iodide (Gustavson, B 7, 731) Formed also by the union of HI with acetylene (Berthelot, A 132, 122, Semenov, Z 186⁵, 725) Oil, v sol alcohol and ether, with alliacious odour

Di-iodo-ethylene $\text{C}_2\text{H}_2\text{I}_2$, ρ CHI CHI *Acetylene di iodide* [73⁵] (192^o cor) SG 2 3302 Formed by passing acetylene over iodine moistened with alcohol (Sabanejeff, A 178, 109, 216, 275, Plimpton, C J 41, 392) Elastic needles (from alcohol) It appears to be accompanied by a small quantity of a liquid isomeride SG 2 2942 With alcoholic AgNO_3 , it forms long needles of a compound $\text{C}_2\text{H}_2\text{I}_4\text{AgNO}_3$, which is decomposed by HCl, giving off acetylene

Tetra-iodo-ethylene Cl_2Cl_2 *Di carb t-tetra-iodide* [c 165⁵] Prisms Formed by the action of a solution of iodine in aqueous KI upon the cuprous compound of potassium propargylate. Formed also by the action of the

iodine solution upon acetylene copper (Hemcolls & Stolz, B 18, 2283)

IODO-ETHYLDENE DI-ETHYL DI-SULPHONE $\text{CH}_3\text{CH}(\text{SO}_2\text{Et})_2$ [109⁵] From ethyldene diethyl di sulphone by boiling with iodine (Fromm, A 253, 146) Needles

IODO-DI-ETHYL OXIDE $\text{C}_4\text{H}_{10}\text{IO}$, ρ $\text{CH}_3\text{CH}_2\text{CH}_2\text{OEt}$ (155^o) SG 2 1692 VD 691 (obs and calc) Formed by heating ethylene iodide with alcohol at 75^o (Baumstark, B 7, 1172) Formed also from the mono ethyl derivative of glycol by treatment with iodide of phosphorus (Demole, B 9, 746) Pungent oil, not decomposed by water Alcoholic potash attacks it energetically, yielding $\text{CH}_3\text{CH}_2\text{OEt}$ (35^o), and $\text{CH}_3(\text{OEt})\text{CH}_2(\text{OEt})$ (17^o) Boiling with reduced silver does not affect it

IODO-(β)-ETHYL-THIOPHENE

$\text{C}_6\text{H}_4(\text{C}_2\text{H}_5)\text{IS}$ Oil Formed by the action of iodine upon (β) ethyl thiophene in presence of HgO (Bonz, B 18, 551)

IODO-FLUORO-BENZENE v **FLUORO IODO BENZENE**

IODOFORM CHI_3 , *Tri-iodo methane* Mol w 394 [119⁵] SG 2

Depression of freezing point of benzene by iodoform Raoult, A Ch [6] 2, 88, Paterno, B 22, 465

Formation —1 By heating alcohol with iodine and caustic or carbonated alkali (Strullus A Ch [2] 20, 314) Iodoform is formed in like manner by the action of iodine and potash or aldehyde, acetone, lactic acid, and many other substances (cf vol 1 p 96) —2 From chloroform and HI (Baeyer, B 5, 1091) —3 By heating chloroform with CaI_2 at 75^o (Spindler, A 231, 263) —4 Together with carbamic ether, by the action of iodine on sodium carbamic ether (Mulder, B T C 7, 333)

Preparation —1 Alcohol containing about 20 p.c. aldehyde is mixed with ten times its weight of aqueous NaOH , iodine is added, and the mixture stirred from time to time The iodoform quickly separates in the cold (Günther, Ar Ph [3] 25, 373) —2 To prepare iodoform R. Rother (Ph [3] 4, 593) heats 32 pts iodine, 32 potassium carbonate, 16 alcohol of 9 per cent and 80 water, till the mixture becomes colourless, then decants the clear liquid, collects the separated crystals of iodoform, and mixes the filtered liquid with 16 to 24 pts hydrochloric acid and 2 to 3 pts potassium dichromate The liquid is then neutralised with potassium carbonate, and 32 pts more of that salt are added, together with 6 pts iodine and 16 alcohol The reaction having been completed at the heat of the water bath, the product is treated as above, whereby a fresh quantity of iodoform is obtained —3 By the action of excess of sodium hypochlorite on an aqueous solution of acetone (6 pts), potassium iodide (50 pts), and NaOH (2 pts) (Suillot & Raynaud, B [3] 1, 3)

Properties —Hexagonal yellow tables, $\alpha = 1.9015$ (Rammelsberg & Kokscharoff, C C 1857, 524, cf Dogiel, N Peter's Acad Bull 20, 337) Above its melting-point it partly decomposes, giving off iodine and HI Has a peculiar persistent odour Volatile with steam Insol water, acids, and alkalis, v sol⁵ alcohol, ether, and fixed and volatile oils An alcoholic solution of iodoform is decomposed under the influence of

light. The decomposition is accelerated by dry oxalic acid, iodine and methylene iodide are produced (Mulder, *R T C* 7, 316, cf. Humbert, *J Ph* [8] 29, 352). Does not in the least hinder the putrefaction of pancreas at 35° (Boillat, *r pr* 183, 308).

Detection—An alcoholic solution of iodoform warmed with aqueous KOH and a little phenol forms a red substance, which dissolves in dilute alcohol, giving it a crimson colour (Lustgarten, *M* 3, 717).

Reactions—1 Heated in a sealed tube at 150°, either alone or with iodine, it yields methylene iodide and brown products (Hofmann, *C J* 13, 65).—2 Bromine gives bromoform (Löschner, *B* 21, 410), not an excess of Br at high temperatures forms CB_3 .—3 Distilled with $HgCl_2$ it yields C^2Cl_2I (Schlagdenhaufen, *J Ph* [8] 29, 247).—4 Mercuric oxide forms CO, formic acid, HgI_2 , and water.—5 Boiling aqueous KOH forms a little potassium formate.—6 Boiling alcoholic potash forms methylene iodide (Bruning, *A* 104, 187, Butlerow, *C R* 47, 595).—7 NaOEt forms methylene iodide, NaI, aldehyde, acrylic acid, and $CH_3CH(OEt)CO_2H$ (Butlerow, *A* 107, 110, 114, 204, 118, 325).—8 K_2SO_4 forms $CH_3(SO_4K)$, (Streeker, *A* 148, 90).—9 By the copper zinc couple iodoform may be reduced to methane (Gladstone & Tribe, *C J* 28, 508).—10 Unites with PEt_3 forming $C_3H_7P_3I_4$ (Hofmann, *Pr* 10, 189).—11 PCl_5 forms chloroform. 12 When made into a paste with moist finely-divided silver, acetylene is at once given off. A mixture of ppt silver and copper is even more effective (Cazeneuve, *C R* 97, 1371).—13 Silver nitrate acts readily at ordinary temperatures, forming AgI, nitric acid, and CO, so that by nitrating the liberated acid an estimation of the quantity of iodoform present may be formed (Greshoff, *R T C* 7, 342).—14 Iodoform exposed to direct sunlight is completely oxidised by air, forming CO_2 , iodine, and water (Dacomo, *G* 16, 247).—15 Mercuric acetate is reduced by iodoform to mercurous acetate, CO_2 being evolved. It does not reduce mercuric nitrate (although chloral forms, in this case, mercurous chloride) (Cotton, *J Ph* [5] 16, 481).—16 Isobutyl alcohol (200 g) mixed with sodium (20 g) and iodoform (100 g) gives a violent reaction, the products being formic acid, isobutyric acid, pentenoic acid, OMe , CH_3CO_2H [70°], isobutyl oxy isobutyric acid $C_4H_9O_2$, CO_2H , a lactone of an oxy octoic acid, isobutylene, methyl isobutyl oxide, methylene di isobutyloxyde, a compound $C_7H_{14}O_2$, and other bodies (Gorboff & Kessler, *J R* 1887, 428).

iodo-fumaric acid $C_2HI(CO_2H)_2$. Iodo-maleic acid [184°]. Formed by dissolving acetylene di carboxylic acid in strong aqueous HI (Baudrowski, *B* 15, 2697). Fine glistening crystals. Very soluble in water, alcohol, and ether.

Salts—A'HK small sparingly soluble crystals—A'Ag, crystalline pp—A'Pb 2aq crystalline pp.

iodo-hen-decoic acid $C_{11}H_{21}IO_2$. $CH_3(CH_2)_9CO_2H$ [24°]. From hen-decenoic acid and HI (Ph Brunner, *B* 19, 2224). Crystalline.

iodo heptioic aldehyde $C_6H_{11}IO$. S.G. 12 281. Formed by treating heptioic

(α -nanthic) aldehyde (75 g) diluted with alcohol (100 cc) with iodine (50 g) and iodic acid (20 g). The crude product is purified by treatment with reduced silver. The yield is very bad (Chautard, *A Ch* [6] 16, 170). Very unstable liquid with irritating odour. Decomposed by heat. Easily decomposed by KOH, NaOH, ammonia, and mineral acids.

Reactions—1 Nitric acid gives heptioic aldehyde and heptioic acid.—2 Silver acetate forms octyl acetate (208°).—3 By heating iodo heptioic aldehyde (120 g) dissolved in alcohol with silver cyanide (67 g) there is formed $C_6H_{13}CyCHO$ (177°) S.G. 12 913. This is a colourless liquid which reduces Fehling's solution and ammoniacal $AgNO_3$, but does not form crystalline compounds with aniline or phenyl hydrazine.—4 Silver sulphocyanide forms the corresponding sulphocyanic heptioic aldehyde.—5 Heating with aniline forms $C_6H_5I(NHC_6H_5)$.

iodo heptylene $C_6H_{11}I$. $Pr CH_2Cl CHMe$ or $Pr CH Cl CH_2Me$ (140°–150°). From heptene (*q v*) and HI (Morris, *C J* 41, 179).

iodo hexane $C_6H_{13}I$. Di iodo hexane $C_6H_{11}I_2$. $CH_3CHICH_2CH_2CHICH_3$. **Hexylene iodide** S.G. 12 024. Formed by heating di allyl in a sealed tube for 5 hours with excess of conc HIAq at 100° (Wurtz, *A Ch* [4] 3, 129), or better, by passing gaseous HI into strongly cooled diallyl (Sorokin, *J pr* [2] 23, 18). Oil, gives off iodine when heated. With sodium it gives hexylene and hexenyl iodide. Alcoholic potash forms diallyl. Silver acetate forms hexylene acetate $C_6H_{11}(OAc)$, whence baryta forms di oxy hexane.

Tetra iodo hexane $C_6H_8I_4$ [above 100°]. From diallyl and iodine (Berthelot & De Luca, *A* 100, 363).

TETRA IODO-HEXINENE *v* **Tetra iodide** of DIPROPARGYL.

iodo-hexoic acid $C_6H_{11}IO_2$. Formed by mixing hydrosorbic acid with conc HIAq at 0° (Fittig, *A* 200, 44). Oil, turning yellow on exposure to light. May be reduced by sodium amalgam to *n*-hexoic acid.

iodo hexylene $C_6H_{11}I$. $CH_2CHCH_2CHICH_2CH_3$. **Hexenyl iodide**. **Diallyl hydronolide** (165°) S.G. 12 1497. Formed, together with di iodo hexane, by the action of HI on diallyl (Wurtz, *A Ch* [4] 3, 155). Formed also by the action of alcoholic potash or of an alloy of tin and sodium on di iodo hexane $CH_2CHICH_2CH_2CHICH_2CH_3$. When treated for 24 hours with moist Ag_2O it forms diallyl, hexylene, and two liquids $C_6H_{12}O$ (d 135°) and $C_{12}H_{24}O$ (180°).

Iodo hexylene $C_6H_{11}I$ (131°) S.G. 12 192. Formed from the hexenyl alcohol obtained by distilling glycerin with lime (Destrem, *A Ch* [5] 27, 58).

Iodo hexylene $C_6H_{11}I$ (142°–145°). From pinacone hydrate and HI at 160° (Bouchardat, *Z* 1871, 699). Reduced by tin and HCl to hexylene. Bromine gives crystalline $C_6H_8Br_2$.

iodo hippuric acid $C_9H_{11}NO_3$. $NH_2CH(CO_2H)(?)$. Formed by treating a boiling alcoholic solution of hippuric acid with iodine (Maier, *Z* 1865, 415). White needles. Decomposes at 90°. All its salts are soluble in water excepting the silver salt.

Iodo-hippuric acid $C_6H_4I.CO.NH.OH.CO_2H$
Formed by the action of aqueous HI on the sulphate of diazo hippuric acid (Griess, *Z* [2] 4, 725, *B* 1, 190) Laminæ, v sol cold alcohol and ether, m sol hot water, nearly insol cold water The iodine is not easily removed

IODO-HYDROCINNAMIC ACID v Iodo-
PHENYL PROPIONIC ACID

DI-IODO-HYDROQUINONE $C_6H_2I_2(OH)_2$ [5841] [145°] Formed by boiling di-iodo-quinone [180°] with a dilute solution of $SnCl_2$ (Seifert, *J pr* [2] 28, 438, Kehrman, *J pr* [2] 37, 337) Long colourless needles (from hot water) Volatile with steam

Di-iodo hydroquinone $C_6H_2I_2(OH)_2$ [142°] From di-iodo quinone [159°] and aqueous SO_2 (Metzeler, *B* 21, 2555) White needles, v sol hot water, alcohol, ether, and $HOAc$, m sol benzene Reoxidised by $FeCl_3$ to di-iodo quinone

Di-acetyl derivative $C_6H_2I_2(OAc)_2$ [148°] Needles or plates (from alcohol), insol water, v sol alcohol and ether, sl sol cold $HOAc$

IODO HYDROTHYMOQUINONE
 $C_8H_8MePr(OH)_2$ [52641] [74°] Obtained by reducing iodo thymoquinone with $SnCl_2$ (Kehrman, *J pr* [2] 39, 392) Colourless prisms, v sol organic solvents

IODO HYDRO TOLUQUINONE
 $C_8H_8Me(OH)_2$ [6241] [111°] From the corresponding quinone, by reduction with $SnCl_2$ (Kehrman, *J pr* [2] 39, 392) Soft silky aggregates of needles, sol organic solvents

IODOL v **TETRA IODO PYROLE**

IODO-LACTIC ACID v **IODO OXY PROPIONIC ACID**

IODO-MALEIC ACID v **IODO FUMARIC ACID**

IODO MELLILIC ACID *Methyl derivative*
 $C_8H_8IO_2$, v $C_8H_8(OMe)_2$ $C_6H_4I.CO_2H$ From the methyl derivatives of (a) and of (β) coumaric acid and fuming aqueous HI in the cold (Perkin, *C J* 39, 429) Aqueous Na_2CO_3 forms $C_8H_8(OMe)CH_2CH_2$ and CO_2

IODO METHANE v **METHYL IODIDE**

Di-iodo-methane v **METHYLENE IODIDE**

Tri-iodo methane v **IODOFORM**

Tetra-iodo-methane CI_4 *Carbon tetra iodide*
SG 22 432 Formed by mixing CCl_4 with aluminium iodide dissolved in CS_2 (Gustavson, *A* 172, 173, *C R* 78, 882) Formed also by heating CCl_4 with CaI_2 at 75° (Spindler, *A* 231, 264) Dark red regular octahedra (Friedel, *Bl* [3] 21, 482) Sol CS_2 , alcohol, ether, and MeI May be kept for some days, but gradually decomposes The decomposition is hastened by both CS_2 and CO_2 Above 80° it quickly splits up into carbon and iodine Converted into iodo form by boiling with aqueous HI, and even by boiling with water Scarcely attacked by aqueous potash or H_2SO_4 Chlorine converts it into CCl_4 Br gives CBr_4

IODO-DI METHYL AMINE v *Di methyl-iodo-amine* under **DI METHYL AMINE**

IODO-DI-METHYL-ANILINE C_6H_4IN v $C_6H_4INMe_2$ [79°] Formed by adding iodine to a solution of di-methyl aniline in CS_2 (Weber, *B* 10, 765) Formed also by the action of cyanogen iodide on di-methyl aniline in the cold, heat being evolved and HCN given off (Merz & Weith, *B* 10, 757). White laminæ, sol alcohol

and $HClAq$ Not attacked by caustic soda When heated above 80° it gives off HI and leaves a residue which forms a deep violet solution in alcohol — $B' F.PtCl_2$

IODO-TRI METHYL-BENZENE v. Iodo ψ

CUMENE

IODO METHYL-BUTYL-BENZENE v Iodo-BUTYL-TOLUENE

DI IODO METHYLENE **DI ETHYL DI-SULPHONE** $Cl_2(SO_2Et)_2$ [177°] Formed from methylene di ethyl di sulphone I, and $KIAq$, by exposure to sunlight (Fromm, *A* 253, 161) Needles, sl sol boiling water

DI-iodo-METHYLENE OXIDE $C_2H_2I_2O$ v $(CH_2I)_2O$ (219°) From dry 'oxymethylene' (formic paraldehyde) and gaseous HI (Tishchenko, *J R* 1887, 464) Oil

IODO TRI METHYL PIPERIDINE $C_8H_{11}IN$ [60°] Formed by heating ethyldiene diacetamide with HI (E Fischer, *B* 17, 1796) Colourless rectangular prisms Nearly insol water — $B'HI$ very sparingly soluble

Iodo-tetra-methyl-piperidine $C_8H_{11}NI$ [90°] Formed by heating triacetone with HI at 150° (E Fischer, *B* 17, 1791) Easily soluble in alcohol and ether, insol water Colourless tables (from ether)

IODO DI METHYL THIOPHENE C_6H_4IS v

CI CMe }
 CH CMe } S (97°) From di-methyl thiophene (from coal tar), iodine, and HgO (Messinger, *B* 18, 1638) Oil

Iodo - tri - methyl - thiophene C_6H_3IS v

CMe CMe }
 CI CMe } S Formed by the action of iodine (48 g) and HgO (21 g) on tri-methyl thiophene (12 g) dissolved in ligroin (24 g) (Zelinsky, *B* 21, 1837) Non volatile oil

(a) **IODO NAPHTHALENE** $C_{10}H_7I$ (305°)

Formation — 1 By adding iodine to a solution of mercury dinaphthyl $Hg(C_{10}H_7)_2 + 2I_2 = HgI_2 + 2C_{10}H_7I$ (Otto, *A* 147, 173) — 2 From diazo naphthalene sulphate and Li (Nolting, *B* 19, 135)

Properties Thick yellowish oil, not solidified at — 17° Miscible with alcohol, ether, CS_2 , and benzene Alcoholic potash at 160° forms some naphthalene Boiling $HIAq$ (127°) completely converts it into naphthalene When a solution in CS_2 is boiled with aluminium chloride there is formed naphthalene, iodine, and tarry matter, but no (β) iodo naphthalene (Roux, *Bl* [2] 45, 517)

Picric acid compound [127°] Golden yellow needles

(β) **Iodo-naphthalene** $C_{10}H_7I$ [55°] Prepared by the action of HI on (β) diazo naphthalene sulphate (P Jacobson, *B* 14, 804) Colourless plates, sol ether, alcohol, and $HOAc$ Volatile with steam

(α, α) **Di-iodo-naphthalene** $C_{10}H_6I_2$ [14] [110°] From (α) iodo (α) nitro naphthalene by reduction, and treatment of the resulting iodo naphthylamine with H_2SO_4 and $NaNO_2$, followed by HI (Meldola, *C J* 47, 522) Needles (from alcohol)

(α, β) **Di-iodo-naphthalene** $C_{10}H_6I_2$ [12] [81°] From (β)-iodo-(α)-nitro-naphthalene in

the same way as the preceding (Meldola) Scales (from alcohol)

(*β*) - IODO - NAPHTHALENE SULPHONIC ACIDS $C_{10}H_7I(SO_3H)$ Two isomerides are formed by sulphonation (*β*) iodo-naphthalene (Armstrong & Wynne, *C J Proc* 3, 22) One of the isomerides forms the salts KA' and BaA' , 4 $\frac{1}{2}$ aq, both crystallising in hexagonal scales, the other forms the salts KA' & Ca' crystallising in laminæ, and BaA' , 2aq in flat needles

(1, 5) Iodo naphthalene sulphonic acid $C_{10}H_7I(SO_3H)$ [129°] Formed from (a) diazo naphthalene sulphonic acid and warm $HIAq$ (40 °c) (Mauzelus, *B* 22, 2820) Colourless tables (containing 2aq) v sol. water

Salts— $A'K$ aq plates m sol water— $A'Na$ aq indistinct needles— $A'Ag$ plates S 66— $A'Ca$ 2aq scales, sl sol water— $A'Ba$ aq scales S 23 (in the cold) S 1 at 00°— $A'Mg$ needles sl sol water— $A'Zn$ 6aq scales, m sol water— $A'Cu$ 4aq greenish white needles, sl sol water— $A'Pb$ 4aq sl sol. water— $A'Mn$ 4aq indistinct crystals sl sol water

Methyl ether MeA' [60°] Prisms v sol Et_2O , sl sol cold $EtOH$

Ethyl ether EtA' [74°] Six sided tables v sol Et_2O

n Propyl ether PrA' [67°] Colourless tables

Isopropyl ether PrA' [90°] Prisms Chloride $C_{10}H_7ISO_2Cl$ [114°] Monoclinic prisms v sol hot $AcOH$, sl sol ligroin

Bromide [153°] Prisms

Amide $C_{10}H_7I(SO_2NH_2)$ [239°] Scales

(a) IODO (*β*) NAPHTHOL $C_{10}H_7I(OH)$ [12] [94.5°] (M), [c 100°] (W) Prepared by dissolving equal parts (20 g) of (*β*) naphthol, lead acetate, and dried sodium acetate in $HOAc$, cooling, and gradually adding iodine (35.2 g) dissolved in hot $HOAc$ The product is pptd by water and recrystallised from dilute alcohol (Meldola, *C J* 47, 527) Formed also by the action of iodide of nitrogen on a dilute alcoholic solution of sodium (*β*) naphthol (Willgerodt, *J pr* [2] 37, '48)

Properties—Long colourless needles, sl sol boiling water, v sol organic solvents Volatile with steam Sol cold dilute $KOHAq$, decomposed by hot alkalis Nitric acid liberates iodine $KMnO_4$ gives phthalic acid

(a) IODO (a) NAPHTHYLAMINE

$C_{10}H_7I(NH_2)$ [41] From (a) iodo (a) nitro-naphthalene, zinc dust, and $HOAc$ (Meldola, *C J* 47, 521) Its solution rapidly oxidises in the air forming a red colouring matter— $B'H_2SO_4$, tolerably stable white needles

Acetyl derivative $C_{10}H_7I(NHAc)$ [196°] From the preceding by boiling with Ac_2O (M) Needles (from alcohol) Gives a nitro derivative [286°]

IODO-*o* NITRO ANILINE $C_6H_4I(NO_2)(NH_2)$ [52.1] Formed by heating *o* iodo nitro-benzene [168°] with alcoholic NH_3 at 170° for several days (Körner, *G* 4, 386) Large steel blue laminæ (from alcohol in sealed tubes) yellow by transmitted light Does not melt at 220° Not attacked by nitrous ether

Iodo *o*-nitro-aniline $C_6H_4I(NO_2)(NH_2)$ [42.1] [122°] Formed by warming a solution of the acetyl derivative of *p* iodo-aniline in $HOAc$ with

HNO_3 (Michael & Norton, *B* 11, 109) Long orange-yellow needles (from alcohol)

Iodo-*p*-nitro-aniline $C_6H_4I(NO_2)(NH_2)$ [24.1] [105.5°] Prepared by the action of iodine chloride (2 pts) on *p* nitro aniline (1 pt) dissolved in dilute $HClAq$ (Michael & Norton, *m* 1, 2f2, *B* 11, 113) Long yellow needles— $B'HCl$ [163°]

Di iodo-*m*-nitro-aniline $C_6H_3I_2(NO_2)_2(NH_2)$ [42.3.1] [145.5°] Formed by passing iodine chloride (3 pts) into a solution of *m* nitro-aniline (1 pt) in $HClAq$ (Michael & Norton, *Am* 1, 255, *B* 11, 112) Long slender yellow needles, v sol cold alcohol, sl sol acetic ether, insol water Its hydrochloride is not decomposed by water

Di-iodo-*p*-nitro-aniline $C_6H_3I_2(NO_2)_2(NH_2)$ [62.4.1] [244°] Prepared by the action of iodine chloride (2 mols) on *p* nitro aniline dissolved in chloroform (M & N) Yellow prisms with blue fluorescence (from alcohol) Sl sol hot alcohol, sol $CHCl_3$ and $EtOAc$, v sol hot nitro benzene It is not basic

o IODO NITRO BENZENE $C_6H_4I(NO_2)$ [12] [49°] Formed, together with the *p* isomeride, by treating iodo benzene with HNO_3 (Körner, *G* 4, 305) The *p* isomeride crystallises first from alcohol Long flat lemon yellow needles Gives a little *o* iodo aniline and much aniline on reduction

m Iodo-nitro benzene $C_6H_4I(NO_2)$ [1.3] [36°] (c 280°) Formed from *m* nitro aniline by displacing NH_3 by *I* through the diazo reaction (Griess, *Z* 1866, 218) Monoclinic plates, *a b c* = 2.296 1.1129 (Panebianco *G* 9, 360) The same body is perhaps formed by the action of ICl on sodium *m* nitro benzoate (Schutzenberger & Segenwald, *Rép Chim pure*, 1862, 144)

p Iodo-nitro-benzene $C_6H_4I(NO_2)$ [1.4] [171°] The chief product of the action of fuming HNO_3 upon iodo benzene (Kukulé, *A* 137, 129) Obtained also from *p* nitro aniline by the diazo reaction Pale yellow needles

Di chloride $C_6H_3I_2(NO)_2Cl_2$ Formed by passing Cl_2 into a solution of iodo nitro benzene in chloroform (C Willgerodt, *J pr* [2] 33, 160) Hardly sol CS_2 , Et_2O , or light petroleum Sol. $CHCl_3$ and benzene At 150° it gives off Cl_2 , leaving $C_6H_3I_2(NO_2)_2$ With alcohol it reacts forming aldehyde, HCl and $C_6H_3I_2(NO_2)_2$

Iodo-*di*-nitro-benzene $C_6H_3I_2(NO_2)_2$ [12.4] [89°] Obtained by nitrating *o* or *p*-iodo nitro-benzene with H_2SO_4 and HNO_3 (Körner, *J* 1875, 322) Yellow triclinic crystals, *a b c* = 1.634 1.940 (La Valle, *G* 10, 3) V sl sol cold alcohol. Hot dilute KOH forms *p* nitro phenol Alcoholic NH_3 gives *di* nitro aniline, though the decomposition is incomplete in the cold

Iodo *di*-nitro-benzene $C_6H_3I_2(NO_2)_2$ [12.6] [114°] Formed in small quantity, together with the preceding, by treating *o* iodo nitro benzene with HNO_3 mixed with H_2SO_4 (Körner, *G* 4, 305) Orange triclinic tables (from alcohol) More sol alcohol and ether than the preceding Converted by heating with alcoholic NH_3 into *di* nitro-aniline [188] May be reduced to phenylene diamine.

Iodo-*tri*-nitro-benzene $C_6H_2I_3(NO_2)_3$ [12.4.6] [164°] From chloro *tri* nitro-benzene and alcoholic KI (Hepp, *A* 215, 361) Golden needles

Converted by boiling aqueous KOH into picric acid

Di-iodo nitro-benzene $C_6H_4I_2(NO_2)$ [134] [168°] Obtained from *m* di-iodo benzene by dissolving in hot fuming HNO_3 (Körner). Tri-methyl octahedra, $a, b, c = 647, 1458$ (La Valle, *G* 10, 2) Sl sol ether, v sl sol cold alcohol By heating for a few days with alcoholic NH_3 at 170° it forms iodo nitro aniline

Di-iodo-nitro-benzene $C_6H_3I_2(NO_2)$ [124?] [1125°] Formed by dissolving *o*-di-iodo benzene in fuming HNO_3 and, after a few minutes, diluting with water (Körner a Wender, *G* 17, 491) Lemon yellow needles or small prisms (from alcohol)

(α)-IODO-NITRO-BENZOIC ACID $C_6H_3INO_3$, *to* $C_6H_4I(NO_2)(CO_2H)$ [32or61] [235°] Formed, together with the two following, by heating *m*-iodo-benzoic acid with conc HNO_3 (Grothe, *J pr* [2] 18, 324, Cunze a Hubner, *A* 135, 106) Sl sol water, especially if HCl be present — Gives *o*-amido benzoic acid on reduction $NH_4A'aq$ — $NaA'3aq$ — $CaA'2aq$ — $SrA'4aq$ — $BaA'3aq$

Ethyl ether EtA' [84°]

(β)-Iodo nitro-benzoic acid $C_6H_3I(NO_2)(CO_2H)$ [36or21] [174°] Formed as above V sol water, especially if HCl be present Melts under water May be reduced to *o*-amido benzoic acid — $NH_4A'aq$ — $LiA'aq$ — $NaA'4aq$ — $KA'3aq$ — CaA' — SrA' — $BaA'6aq$

Ethyl ether EtA' [64°] Yellow plates

(γ)-Iodo-nitro-benzoic acid $C_6H_3I(NO_2)(CO_2H)$ [3x1] [192°] Formed as above V sol water, but does not melt under it — $NaA'aq$ silky yellow needles — $CaA'3aq$ — $SrA'4aq$ — $BaA'3aq$

Iodo-nitro-benzoic acid $C_6H_3I(NO_2)(CO_2H)$ [431] [210°] Formed by heating *p*-iodo benzoic acid with fuming HNO_3 (Glassner, *B* 8, 562) Nearly insol water, v sol alcohol — $NaA'aq$ — $KA'aq$ — $CaA'1\frac{1}{2}aq$

(α, α)-IODO-NITRO-NAPHTHALENE

$C_{10}H_7I_2(NO_2)$ [41] [123°] Formed from acetyl-(α)-naphthylamine by nitration, saponification, diazotisation, and treatment with HI (Meldola, *C J* 47, 519) Minute white needles (from hot alcohol) Sol benzene, HOAc, and acetone May be reduced to (α) naphthylamine

(α, β)-Iodo nitro-naphthalene $C_{10}H_7I_2(NO_2)$ [12] [1085°] Formed from the mother liquor of the preceding (Meldola) Yellow scales May be reduced to (β)-naphthylamine

(β, α)-Iodo-nitro-naphthalene $C_{10}H_7I_2(NO_2)$ [21] [885°] From acetyl (α) nitro (β) naphthylamine by saponifying with hot dilute H_2SO_4 and subsequent displacement of NH_2 by I (Meldola, *C J* 47, 520)

(α)-IODO (β) NITRO-(α) NAPHTHOL

$C_{10}H_7I(NO_2)(OH)$ [421] [146°] Formed by boiling acetyl (4, 2, 1)-iodo nitro-naphthylamine with strong caustic alkali (Meldola, *C J* 47, 524) Yellow needles (from alcohol) Insol cold water, sl sol hot water and hot benzene, v sol alcohol, acetic acid, and acetone Yields phthalic acid on oxidation Its K and Na derivatives form minute orange needles, m sol cold water — $\{C_{10}H_7I(NO_2)\}_2Ba$ 8aq bright red amorphous powder, almost insol. boiling water, deflagrates on ignition

(α)-IODO-(β)-NITRO-(α)-NAPHTHYL-AMINE Acetyl derivative

$C_{10}H_7I(NO_2)(NH_2Ac)$ [421], [286°] From acetyl-iodo naphthylamine by warming its solution in HOAc with HNO_3 at 75° (Meldola, *C J* 47, 524) Stray coloured needles (from alcohol) Sublimes while melting More difficult to saponify by H_2SO_4 than the bromo-compound

IODO NITRO-*o*-OXY BENZOIC ACID

$C_6H_3INO_3$, *ie* $C_6H_4I(NO_2)(OH)(CO_2H)$ From (5, 2, 1) nitro oxy benzoic acid by treatment in alcoholic solution with I and HgO (Weselsky, *A* 174, 108) Slender yellow needles — $KA'2aq$ — $C_6H_5KNO_3$ 3aq — $BaA'6aq$

Iodo nitro *o* oxy benzoic acid

$C_6H_3I(NO_2)(OH)(CO_2H)$ [204°] From (5, 2, 1)-iodo oxy benzoic acid by nitration (Hubner, *B* 12, 1347)

Iodo nitro *m* oxy benzoic acid

$C_6H_3I(NO_2)(OH)(CO_2H)$ Formed by treating an alcoholic solution of nitro *m* oxy benzoic acid with I and HgO (Weselsky, *A* 174, 100) Lemon-yellow crystals, sl sol water, v sol cold alcohol — $BaA'6aq$ minute red needles

Iodo nitro *p* oxy benzoic acid

$C_6H_3I(NO_2)(OH)(CO_2H)$ From nitro *p* oxy-benzoic acid, iodine, and HgO (W) Lemon-yellow needles — $BaA'4aq$ flat red needles $BaC_6H_4INO_2$ 2aq short dark red needles

DI-IODO DI NITRO DI-OXY-DI-PHENYL SULPHONE $C_{12}H_8I_2N_2O_4$, *ie*

$SO_2(C_6H_4I(NO_2)OH)_2$ [205°] Formed by heating iodine (50 g) dissolved in alcohol with a mixture of di-nitro-di-oxy-di-phenyl sulphone (34 g) and HgO (21 g) at 100° (Annaheim, *B* 9, 660) Needles (from HOAc), insol water and alcohol Decomposes alkaline carbonates — $Na_2C_{12}H_8I_2N_2O_4$ 2aq

IODO *o* NITRO PHENOL $C_6H_4INO_3$, *ie*

$C_6H_3I(NO_2)(OH)$ [110°] (Armstrong, *Watts' Dict Ed 1 Suppl* 2, 917, *B* 6, 649) Formed by the action of iodine and HgO on *o*-nitro phenol dissolved in HOAc (Busch, *B* 7, 462, cf Armstrong) Short yellow needles, v sol hot water, alcohol, and ether Moderately volatile with steam — $KA'aq$ garnet red plates with green lustre (A), v e sol hot water and alcohol

Iodo-*p* nitro phenol $C_6H_4I(NO_2)(OH)$ [241],

[93°] (Körner, Armstrong) Formed by the action of iodine and HgO on *p*-nitro phenol dissolved in HOAc (Körner, *Bull Acad Belg* [2] 24, 166, Busch, *B* 7, 462) Also from nitro-amido phenol by the diazo reaction (K) Yellow needles — $NaA'2\frac{1}{2}aq$ (K) — $KA'1\frac{1}{2}aq$ (B) Nitric acid converts it into iodo di-nitro phenol [108°].

Iodo di-nitro phenol

$C_6H_3I(NO_2)_2(OH)$ [6421] [106°] (A), [108°] (W) Formed from (4, 2, 1) di-nitro phenol by treatment with iodine, potassium iodate, and potash (Körner, *G* 4, 397) or with iodine and HgO (Armstrong, *B* 6, 649, Weselsky, *A* 174, 111) Formed also from di-nitro-amido phenol by the diazo-reaction (A), and by the nitration of the preceding iodo nitro phenol (A) Long slender lemon yellow needles (from hot water) Sl sol hot water — KA deep orange needles, v sol hot, sl sol cold, water — $CaA'5aq$ orange red plates, v sol, hot water

Iodo-di-nitro-phenol

$C_6H_3I(NO_2)_2(OH)$ [4621] [113°] Formed from (6, 2, 1)-di-nitro phenol by treatment with iodine

and iodic acid (Körner, *G* 4, 897) or with iodine and HgO (Armstrong, *B* 6, 649) Long, lemon-yellow needles (from water), v sol water and alcohol The potassium derivative forms magnificent crimson needles with green and golden lustre, sl sol water The silver derivative forms small brownish red needles

Di iodo-*o*-nitro-phenol $C_6H_3I_2(NO_2)(OH)$ [6 4 2 1] [98°] From *o* nitro-phenol, iodine, and iodic acid in alkaline solution (Körner) Slender dark yellow needles (from ether alcohol), sl sol water, v sol boiling alcohol and ether—NaA' aq dark brown prisms, with golden lustre—KA' very soluble reddish brown needles

Di iodo *p* nitro phenol $C_6H_3I_2(NO_2)(OH)$ [6 2 4 1] [157°] (K) From *p* nitro phenol, iodine, KIO, and potash (K., cf Seifert, *J pr* [2] 28, 437) Also from *p* nitro phenol *o* sulphonic acid iodine in alcoholic solution, and HgO (Post a Brackebusch, *A* 205, 91) Formed also by treating nitro-*o* oxy benzic acid with iodine and HgO (Weselsky, *A* 174, 177) Large colourless prisms (from ether) turning yellow on exposure to air Decomposes a little above its melting point—KA' golden needles with violet iridescence—NaA' aq efflorescent orange laminae

Di iodo nitro phenols appear also to have been obtained by Piria (*A* 198, 268)

iodo NITRO PHENOL SULPHONIC ACID $C_6H_3I_2NSO_3$ *ie* $C_6H_3I_2(NO_2)(OH)(SO_3H)$ [2 6 1 4] Formed when iodine and HgO are added to an alcoholic solution of *o* nitro phenol *p* sulphonic acid (Armstrong a Brown, *C J* 25, 869)—KA' yellow scales, composed of short needles, sl sol water—K₂C₂H₂INSO₃ red crystals—BaA' aq pale yellow silky needles, sl sol water

Iodo nitro phenol sulphonic acid $C_6H_3I_2(NO_2)(OH)(SO_3H)$ [6 4 1 2] Formed, together with di iodo *p* nitro phenol, by treating an alcoholic solution of *p* nitro phenol *o* sulphonic acid with iodine and mercuric oxide (Post a Brackebusch, *A* 205, 88)—Salts CaC₂H₂INSO₃ 3aq coarse yellow needles, m sol water—BaC₂H₂INSO₃ 3aq long yellow needles, m sol water—Pb₂(OH)₂C₂H₂INSO₃ 2½aq yellow crystalline pp

DI IODO NITRO-RESORCIN $C_6H_2I_2(NO_2)(OH)_2$ From nitro resorcin in alcoholic solution by alternate addition of iodine and mercuric oxide (Weselsky, *A* 174, 111) Golden needles

iodo NITRO-THIOPHENE $C_4H_2I_2(NO_2)S$ [74°] Formed by nitration of iodo thiophene (Kreis, *B* 17, 2073) Glistering yellow prisms

iodo NITRO-TOLUENE $C_7H_4I_2(NO_2)$ *ie* $C_7H_4MeI_2(NO_2)$ [1 4 2] [61°] (286°) From (4,2,1) di-nitro toluene (Heynemann, *A* 158, 397) Pale yellowish crystals V e sol CS₂ and ether

Iodo-nitro-toluene $C_7H_4MeI_2(NO_2)$ [1 4 3] [56°] From *p* toluidine by nitration and displacement of NH₂ by I (Beilstein a. Kuhlberg, *A* 158, 844) Large flat needles, v sol boiling alcohol

Iodo-nitro-toluene $C_7H_4MeI_2(NO_2)$ [1 2 2] [104°] Formed by nitrating *o*-iodo-toluene (B a. K) Minute needles

Iodo nitro-toluene (?) [109°] Formed by nitrating *m*-iodo-toluene (B. a. K.). Small needles.

Iodo di-nitro-toluene $C_7H_3MeI_2(NO_2)_2$ [1 4 5 3] [138°] Formed by nitrating *p*-iodo toluene (Glassner, *B* 8, 561) Crystals

iodo-OCTINOIC ACID $C_{11}H_{11}IO_4$ *ie* $(C_6H_4)ClCO_2H$ Iodo-di-allyl acetic acid from $(C_6H_4)ClCO(OH)CO_2H$ (17 g) and cold fuming HIAq (45 g) (Schatzky, *J R* 17 78) Crystals, insol water, v sol alcohol and ether Easily decomposed

***p* IODO *n*-OCTYL-BENZENE** $C_{18}H_{35}I$ *ie* $C_6H_4(C_6H_4)I$ [1 4] (319°) Heavy oil. Formed by diazotising *p* amido phenyl octane, and treating the diazo-octyl benzene with HI (Beran, *B* 18, 136) On oxidation with CrO₃ it gives *p*-iodo benzoic acid Iodo octyl benzene obtained by the action of iodine and HgO upon *n*-octylbenzene is described by Ahrens (*B* 19, 2720) as an oil, solidifying at -4°, and completely decomposed by distillation

***p*-Iodo sec-octyl-benzene** $C_{18}H_{35}(C_6H_4)I$ [1 4] *p* Iodo capryl-benzene (305° uncor) Formed by diazotising *p* amido phenyl sec octane and treating the diazo capryl benzene with HI Heavy oil. V sol ether and acetic acid, sl sol alcohol It is oxidised by CrO₃ to *p* iodo benzoic acid (Beran, *B* 18, 142)

iodo (a) OCTYL THIOPHENE $C_{11}H_{11}IS$ *ie* $C_6H_4SI(C_6H_4)$ [c 0°] SG $\frac{2}{3}$ 1.2614 From octyl thiophene (10 g) in ligroin by treatment with iodine (10 g) and HgO (11 g) (Schweinitz, *B* 19, 644) V sol ether, cannot be distilled

iodo OLEIC ACID *v* IODO-STEARIDENIC ACID

iodo ORCIN $C_8H_7IO_2$ *ie* $C_8H_7MeI_2(OH)_2$ [86 5°] Formed by dissolving orcin (1 pt) and iodine (2 pts) in ether (6 pts), and gradually adding finely powdered litharge (9 pts) The ether is distilled off, and the residue recrystallised from benzene (Stenhouse, *Pr* 22, 53) Prisms, decomposing when heated alone or with water Sl sol cold water, v sol hot water, alcohol, and ether Has not the astringent sweet taste of orcin

Tri iodo-orcin $C_8H_5I_3O_2$ *ie* $C_8MeI_3(OH)_2$ Formed by adding to a dilute aqueous solution of orcin a quantity of ICl₃, not quite sufficient to ppt all the orcin, and crystallising the pp first from CS₂ and then from boiling alcohol (Stenhouse, *C J* 17, 327) Large transparent plates, tinged with brown V sol CS₂, v e sol ether, m sol alcohol, insol water Becomes brown at 100° Dissolves with decomposition in aqueous KOH Decomposed by hot H₂SO₄ and by hot HNO₃

Iodo-(8)-orcin *v* Iodo BETORCIN

DI-iodo-ORSELLIC ACID Methyl ether $C_8H_7I_2O_4$ *ie* $C_8H_7I_2O_4Me$ Methyl di-iodo-di-oxytoluate Formed by adding a dilute solution of chloride of iodine, containing excess of iodine, to a cold saturated aqueous solution of methyl orsellate (Stenhouse, *A* 149, 295) Needles from CS₂, sol benzene, CS₂, alcohol, and boiling water Decomposed on fusion

Ethyl ether $C_8H_7I_2O_4Et$ Formed in like manner Small needles, almost insol cold water, m sol benzene, CS₂, and boiling alcohol Decomposed on fusion

iodo-*o* OXY-BENZOIC ACID $C_7H_4IO_4$ *ie* $C_7H_3I(OH)(CO_2H)$ [3 2 1] Iodo-salicylic acid. [198°] Formed, together with the following compound, by boiling a solution of salicylic acid

and iodine in alcohol, and separated by fractionally crystallising the product from water (A Miller, *C J* 41, 406, A 220, 124). Long needles, v sol water. Gives a violet colouration with FeCl_3 . Gives the corresponding di oxy benzoic acid on potash fusion— $\text{BaA}'_2 3\frac{1}{2}$ g concentrically grouped needles S 5 at 8° .

Iodo-o-oxy benzoic acid $\text{C}_6\text{H}_4\text{I}(\text{OH})(\text{CO}_2\text{H})$ [5 2 1] [196°] (G), [193 5°] (F), [197°] (M) S 11 at 20° , 1 at 100° (L).

Formation—1 As above—2 Together with di- and tri-iodo oxy-benzoic acids, by fusing salicylic acid (1 mol) with iodine (1 mol), and treating the product with aqueous KOH (Kolbe & Lautemann, A 115, 157)—3 By dissolving equal weights of iodine and salicylic acid in 80 p c alcohol, boiling for 3 hours, evaporating, and dissolving in aqueous Na_2CO_3 (Lautemann, A 120, 299)—4 From salicylic acid, iodine, and HgO (Hlasiwetz & Weselsky, B 5, 380, A 171, 99)—5 By agitating a hot solution of salicylic acid (1 pt) in water (25 pts) with a mixture of iodine (1 pt) and iodic acid ($\frac{1}{3}$ pt), keeping the liquid hot for some time. The resulting acid is converted into sodium salt, and the satiny-needles of the salt of the di iodo acid separated, if necessary by hand picking, from the lancet shaped laminae of the mono iodo acid (Liechti, A Suppl 7, 129, H Fischer, A 180, 346)—6 From the corresponding nitro oxy benzoic acid by reduction to oxy amido benzoic acid and exchange of NH_2 for I by the diazo reaction (Goldberg, J pr [2] 19, 368, P F Frankland, C J 37, 749)—7 By warming dry silver salicylate with iodine (Birnbau & Reinherz, B 15, 458).

Properties—Long needles (from water), sl sol water, v sol alcohol and ether. Gives a violet colour with FeCl_3 . On potash fusion at 200° it gives di oxy benzoic acid [197°]. When suddenly heated it splits up into CO_2 and iodo phenol.

Salts— $\text{NaA}'\text{aq}$ S 77 at 20° (L)— $\text{KA}'_3\text{aq}$ laminae S 19 at 20° (L)— $\text{NH}_4\text{A}'_3\text{aq}$ needles S 95 at 20° (L)— $\text{BaA}'_2\text{aq}$ warty scales S (of BaA'_2) 8 at 8° (M), 13 at 20° (L)— $\text{BaC}_6\text{H}_4\text{IO}_2\text{aq}$ tufts of small needles (L)— $\text{CaA}'_2\text{aq}$ — $\text{MgA}'_2\text{aq}$ — PbA'_2 — AgA' yellowish pp.

Ethyl ether EtA' [71°] (Schmitt, Z 1864, 321).

Iodo-m-oxy-benzoic acid $\text{C}_6\text{H}_3\text{I}(\text{OH})(\text{CO}_2\text{H})$ [x 3 1] Formed, together with di iodo phenol, by alternately adding iodine and HgO to oxy benzoic acid dissolved in 90 p c alcohol, and separated by solution in boiling water (Weselsky, A 174, 105). Slender needles, sl sol cold water.

Iodo-p-oxy-benzoic acid $\text{C}_6\text{H}_3\text{I}(\text{OH})(\text{CO}_2\text{H})$ [3 4 1] [160°] (P) S 18 in the cold.

Formation—1 By boiling a solution of p-oxy-benzoic acid for a few minutes with iodine and iodic acid (Peltzer, A 146, 288)—2 From p oxy benzoic acid dissolved in alcohol by alternate addition of iodine and HgO (Weselsky, A 174, 99).

Properties—Small needles (from water). Decomposes at 152° . May be sublimed below its melting-point V e sol alcohol and ether. Gives with FeCl_3 a dingy brown pp.

Salts— $\text{NaA}'_2\text{aq}$ monochrome efflorescent crystals.— $\text{Na}_2\text{C}_6\text{H}_3\text{IO}_2\text{aq}$. hygroscopic silky

needles (from alcohol)— $\text{BaA}'_2 7\text{aq}$ trimetric tables— AgA' white pp.

Methyl derivative $\text{C}_6\text{H}_3\text{I}(\text{OMe})(\text{CO}_2\text{H})$
Iodo anisic acid [235°] S (cold ether) 7. Formed by heating anisic acid with iodine and iodic acid at 150° (P). Formed also by oxidation of the methyl ether of iodo p cresol (Schall & Dralle, B 17, 2538). The same, or an isomeric acid, is formed from amido anisic acid by the diazo reaction (Griess, *Pr*-10, 309). Plates (S & D) or needles (G). Nearly insol boiling water, m sol alcohol— $\text{NaA}'_2\text{aq}$ concentrically grouped needles— $\text{BaA}'_2 3\text{aq}$ vitreous prisms— $\text{CaA}'_2 3\text{aq}$ nacreous laminae— PbA'_2 (at 100°): curdy pp— AgA' micro-crystalline laminae.

Di-iodo-o oxy-benzoic acid $\text{C}_6\text{H}_2\text{I}_2(\text{OH})(\text{CO}_2\text{H})$
Di iodo salicylic acid S 07 at 15° , 15 at 100° (L). Formed, together with iodo o-oxy-benzoic acid, by the action of iodine and aqueous potash, of iodine and iodic acid, or of iodine and HgO upon salicylic acid (Lautemann, A 120, 304, Liechti, A Suppl 7, 141, Demole, B 7, 1439, Weselsky, A 174, 103). Formed also by heating dry silver salicylate with iodine (Birnbau & Reinherz, B 15, 459). White felted mass (from hot water). V sol alcohol and ether. At 197° (L) or 220° (W) it begins to decompose, giving off iodine. It gives a violet colouration with FeCl_3 . On potash fusion it gives tri oxy benz. ic (? gallic) acid and pyrogallol.

Salts— $\text{NaA}'_2\text{aq}$ long flat needles, mostly grouped in druses S 2 at 20° , much less soluble in water than iodo o oxy benzoic acid— $\text{KA}'_3\text{aq}$ minute thick prisms S 553 at 20° . V sol alcohol, sl sol ether— $\text{NH}_4\text{A}'_3\text{aq}$ arborescent groups of small needles S 32 at 20° — $\text{BaA}'_2 3\text{aq}$ needles S 074 at 18° . V sl sol alcohol— $\text{BaC}_6\text{H}_2\text{I}_2\text{O}_2\text{aq}$ small silky tablets, v sl sol water, forming an alkaline solution— $\text{CaA}'_2\text{aq}$ needles S 086 at 18° .

Di iodo-p oxy benzoic acid
 $\text{C}_6\text{H}_2\text{I}_2(\text{OH})(\text{CO}_2\text{H})$ Formed, together with iodo p oxy benzoic acid, by iodation of p oxy benzoic acid (Peltzer). Small needles (from dilute alcohol). Nearly insol boiling water, v e sol alcohol and ether. Decomposes when heated without previous fusion. Cannot be sublimed— $\text{NaA}'_7\text{aq}$ tufts of delicate, iridescent, efflorescent needles, v sol water— $\text{NaC}_6\text{H}_2\text{I}_2\text{O}_2\text{aq}$ trimetric tables— BaA'_2 gelatinous pp got by adding alcohol to its aqueous solution— $\text{CaA}'_2 2\text{aq}$ nacreous laminae— PbA'_2 bulky pp Swells up like mercuric sulphocyanide when heated— AgA' — $\text{Ag}_2\text{C}_6\text{H}_2\text{I}_2\text{O}_2$.

Tri iodo o oxy benzoic acid
 $\text{C}_6\text{H}_2\text{I}_3(\text{OH})(\text{CO}_2\text{H})$ [c 157°] Obtained in small quantity in preparing mono, and di iodo o oxy benzoic acids by the action of iodine and KOH on salicylic acid (Lautemann). Weselsky (A 174, 104) could not obtain it by treating salicylic acid with iodine and HgO . Tufts of needles (from alcohol). Insol water, sol alcohol and ether. Decomposed by alkalis into CO_2 and a red body $\text{C}_6\text{H}_2\text{I}_3\text{O}$ (?). Its sodium salt is a grey-green mass, v sl sol water.

IODO p-OXY-BENZOIC ALDEHYDE $\text{C}_6\text{H}_3\text{IO}_2$, *i.e.* $\text{C}_6\text{H}_3\text{I}(\text{OH})\text{CHO}$ [199°] Formed by heating the dilute alcoholic solution of p oxy benzoic aldehyde with iodine for some hours (Herzfeld, B 10, 2196). Sl sol. water and benzene, v sol

alcohol and ether. Converted by potash fusion into protocatechuic acid.

Iodo di-oxy-benzoic aldehyde *Methyl derivative* $C_6H_4IO_2$, i.e. $C_6H_4I(OH)(OMe)CHO$ *Iodo vanillin* [174°] Formed by warming vanillin with an alcoholic solution of iodine (Carles, *Bl* [2] 17, 12). Needles. Sol. cold alcohol and ether.

Di iodo-di-oxy-benzoic aldehyde *Methyl derivative* $C_6H_3I_2(OL)(OMe)CHO$ Formed like the preceding, using more iodine (C). Crystals, insol. chloroform, sol. alcohol and ether.

α IODO- β -OXY-PHENYL PROPIONIC ACID $C_9H_7IO_3$, i.e. $C_6H_4CH(OH)CHI CO_2H$ [138°] Formed by treating cinnamic acid with an aqueous solution of iodine chloride, the compound $C_6H_4CHCl CHI CO_2H$ being probably first formed (Erlenmeyer & Rosenhek, *B* 19, 2464). Large crystals (from benzene). With HCl it gives the compound C_6H_4CHClO , which may possibly be $C_6H_4CH(OH)C(OH)C(OH)CHClO$.

Ezo Iodo- α oxy phenyl-propionic acid *Methyl derivative* $C_6H_4(OMe)C_2H_4I CO_2H$ Formed by the combination of the methyl derivative of (a) or (b) coumaric acid with HI (Perkin, *C* J 39, 429). Decomposed by aqueous Na_2CO_3 into CO_2 , HI, and $C_6H_4(OMe)C_2H_4$.

TETRA IODO-DI OXY DI PHENYL SULPHONE $C_{12}H_4I_4SO_2$, i.e. $SO_2(C_6H_4I)_2$ [260°-270°] SG 1.2797. From di oxy di phenyl sulphone by treatment in alcoholic solution with iodine and HgO (Annaheim, *B* 9, 1150). Minute needles (from $HOAc$). Decomposes on fusion. Insol. cold alcohol, nearly insol. boiling alcohol and $HOAc$.

β IODO- α OXY-PROPIONIC ACID $C_6H_4IO_3$, i.e. $CH_2I CH(OH) CO_2H$ *Iodo lactic acid* [101°] (M), [85°] (G). Formed by treating β chloro α oxy propionic acid with KI at 10° (Ginsky, *B* 6, 1257). Prepared by the addition of HI to sodium glycidate (Melikoff, *B* 14, 917). Large prisms, v. sol. water, alcohol, and ether. Converted by alcoholic KOH into glycidic acid— AgA' white unstable pp— ZnA' crystalline powder (M) or tables (G)— CaA' 3sq. amorphous (M).

DI IODO-OXY-PYRIDINE $C_5NH_4I_2(OH)$ [245°] (?) [259°] Formed by heating an alkaline solution of pyridine di carboxylic acid (quinolinic acid) with iodine and KI at 180°-200°. Small flat needles. Sol. hot acetic acid and amyl alcohol, v. sol. boiling water, alcohol, ether, or chloroform. Dissolves in dilute alkalis— $C_5NH_4I_2(ONa)3sq$ colourless glistening scales, sl. sol. aqueous $NaOH$ (Pfeiffer, *B* 20, 1352).

IODO-(Py 3)-OXY QUINOLINE $C_8H_6NOI_2$, i.e. $C_8H_4\begin{matrix} Cl & CH \\ \diagdown & / \\ N & C(OH) \end{matrix}$ or $C_8H_4\begin{matrix} CH & Cl \\ / & \diagdown \\ N & C(OH) \end{matrix}$ *Iodo carbostyryl* [76°] Formed by boiling α amido phenyl propionic acid $C_6H_4(NH_2)C(CO_2H)$ with dilute HI (Bayer & Bloem, *B* 15, 2149). Sublimable.

DI-iodo-DI-OXY TOLUIC ACID v. **DI-iodo-ORSELLIC ACID**

IODO-PENTANE v. **AMYL IODIDE**
Di-iodo-pentane $C_5H_{12}I_2$, i.e. $(CE_2CHI)_2CH_3$ (c 183°). Formed by heating methylene di-

methyl diketone $(CH_3CO)_2CH_2$ with HI at about 90° (Combes, *A Ch* [6] 12, 235). Liquid, begins to decompose at its boiling point.

IODO-PENTINENE $C_5H_4I_2$, i.e. $(CH_2)_2CH C OI$ (140°) Formed from the silver derivative of $(CH_2)_2CH C O H$ by treatment with a solution of iodine in KI (Eltzoff, *J R* 9, 225). Liquid. Gives $(CH_2)_2CH C O H$ when heated with $NaOEt$.

DI-iodo DIPHENIC ACID v. **DI-iodo-DIPHENYL DI CARBOXYLIC ACID**
 α IODO-PHENOL $C_6H_4IO_2$ [2] $C_6H_4I(OH)$ [43°]

Formation—1 Probably occurs among the products of the iodation of phenol (Schutzenberger & Sengenwald, *C R* 54, 197, Körner, *A* 137, 197, Hlasivetz & Weselsky, *Sitz W* 60 [2] 290, Lobanoff, *B* 6, 1251)—2 By the action of iodine on sodium phenol suspended in CS_2 (Schall, *B* 16, 1897)—3 By heating the chloride or sulphate of α diazo phenol with KI, distilling the product with steam, and recrystallising from water (Nöling & Wrzesinsky, *B* 8, 820, Nöling & Stricker, *B* 20, 3018, *Bl* [2] 49, 659, Neumann, *A* 241, 68)—4 By adding powdered iodine to a dilute alcoholic solution of phenol, mixed with ammonia (Willgerodt, *J pr* [2] 37, 446).

Properties—White needles, v. sol. water and other ordinary menstrua. According to Schall (*B* 20, 3363) it forms in crystalline branches, melting at 43° or needles melting at 40°. Nitric acid attacks it, setting iodine free, but chlorine does not do so, but forms chloroiodo phenol. Potash fusion at 165°-250° yields pyrocatechin. Not affected by air and light. Cold conc. H_2SO_4 produces di iodo phenol (Neumann, *B* 20, 581).

m-Iodo phenol [3] $C_6H_4I(OH)$ [40°] Prepared from *m* iodo aniline by diazo reaction. The product is distilled with steam, extracted with ether, and recrystallised from ligroin (N & S). It may be prepared in like manner from *m* amido phenol, by diazotising and heating the product with conc. KI. Needles (from ligroin). May be sublimed. V. sol. alcohol and ether. It does not give off iodine when treated either with HNO_3 or with chlorine. It yields resorcin when fused with KOH.

p Iodo phenol [4] $C_6H_4I(OH)$ [94°]

Formation—1 In the iodation of phenol—2 From *p* amido phenol by diazotising and heating the product with $KIAq$ (N & S)—3 A by product, together with di and tri iodo-phenol, in the formation of *o* iodo phenol from iodine, ammonia, and an alcoholic solution of phenol (Willgerodt, *J pr* [2] 37, 446).

Properties—Long needles. Nitric acid sets iodine free, but chlorine does not do so. When heated with conc. H_2SO_4 it gives (1, 3, 6) di iodo-phenol [72°]. Potash fusion gives resorcin at high temperatures.

Di-iodo-phenol $C_6H_3I_2(OH)$ [421] [72°] Formed by mixing *o* iodo phenol (10 g) with H_2SO_4 (30 g) at -10° (Neumann, *A* 241, 71). Formed also in like manner from *p*-iodo phenol. White needles (from water). Volatile with steam. Boiling HNO_3 converts it into picric acid.

Acetyl derivative $C_6H_3I_2(OAc)$ [76°]. Long flat trimetric prisms (from dilute alcohol); *a.b.c.* = 751 : 1 : 832.

Di-iodo-phenol $C_6H_4I_2(OH)$ [68°] Formed as a by product in the action of iodine upon phenol-sodium suspended in CS_2 (Schall, B 16, 1899, 1902, 20, 3364) Apparently formed also in the action of iodine chloride on phenol (S & S) Wh'rs glistening plates Volatile with steam — $C_6H_4I_2ONa$ needles

Acetyl derivative $C_6H_4I_2(OAc)$ [107° uncor], small prisms

Benzoyl derivative $C_6H_4I_2(OBz)$ [96° uncor]

Di iodo phenol $C_6H_4I_2(OH)$ [160°] Formed by the action of iodine and HgO on an alcoholic solution of phenol (Hlasiwetz & Weselsky, *Satz W* 60 [2] 290, C C 1870, 63) Silky felted needles (from dilute alcohol), v sol alcohol, ether, and CS_2 . May be sublimed Not affected by boiling alcoholic KOH

Tri iodo-phenol $C_6H_3I_3(OH)$ [6 4 2 1] [155°]

Formation—1 By treating phenol with a considerable quantity of ICl , and exhausting the product with boiling alcohol in which tri iodo-phenol is not very soluble (Schutzenberger, *Bl* [2] 4, 102)—2 From phenol, iodine, and KOH (Lautemann, A 120, 307)—3 From phenol, iodine, and iodic acid (Körner, A 137, 213)—4. From salicylic acid, iodine and iodic acid (Kekulé, A 131, 231)—5 Formed as a by product from the action of iodine on phenol sodium suspended in CS_2 (Schall, B 16, 1899)—6 By the action of iodine of nitrogen on a dilute alcoholic solution of sodium phenolate (Willgerodt, *J pr* [2] 37, 447)

Properties—Needles (from dilute alcohol) Decomposed on fusion M sol alcohol Converted by excess of ICl into per chloro-phenol HNO_3 gives picric acid HCl and $KClO_3$ gave chloranil

DI-IODO-PHENOL SULPHONIC ACID

$C_6H_3I_2(OH)(SO_3H)$ [6 2 1 4] [120°] Formed by adding a solution of KI and KIO_3 to one of phenol *p*-sulphonic acid in aqueous HCl (Kehrmann, *J pr* [2] 37, 11, 334, 359, Osteryayer, *J pr* [2] 37, 215) Monoclinic prisms c sol water, but ppp by HCl or H_2SO_4 , decomposes at 190° Converted by nitric acid to picric acid Chromic acid oxidises it to di iodo quinone

Salts— KA 2aq long needles or thick prisms— NaA 3aq sol water, commercially known as 'sodazole'— $C_6H_3I_2K_2SO_3$ dimetric prisms— BaA , 3aq shining needles, v sl sol water— ZnA , 6aq long needles The copper salt is greenish white and v sol water

DI-p-IODO-DIPHENYL $C_{12}H_8I_2$

$C_{12}H_8I_2$ [202°] Formed by the action of HI on the diazo-compound derived from benzidine (Schmidt & Schultz, B 12, 489) Yellow leaflets

o-IODO-PHENYL-ACETIC ACID $C_8H_7IO_2$

$C_8H_7IO_2$, CO_2H [96°] Prepared by digesting its nitrile with fuming HCl for four hours at 126° The nitrile is formed by treating o-iodo-benzyl bromide with KCy (Mabery & Robinson, *Am* 4, 102) Slender needles (from water), sol hot water, alcohol, ether, CS_2 , and ligroin— AgA curdy pp; sl sol water

p-Iodo-phenyl-acetic acid $C_8H_7IO_2$, CO_2H [186°] Prepared by heating its nitrile with fuming $HClAq$ in sealed tubes at 100° (Jackson, *Mabery, Am* 2, 253, *P Am* A 18, 205, B 11, 56). Narrow white plates (from water) with

agreeable odour like sweet allysum, v sol hot water, alcohol, ether, benzene, and CS_2 . Gives *p*-iodo benzoic acid on oxidation— BaA , aq minute white needles, v sol water— AgA glistening plates, sl sol boiling water

Nitrile $C_8H_6I_2CH_2CN$ *p* Iodo benzyl cyanide [50 5°] Prepared by boiling *p*-iodo benzyl bromide with alcoholic KCy Pearly plates insol water, v sol alcohol, ether, and CS_2

IODO PHENYL-ACETYLENE C_8H_5Cl Obtained from phenyl acetylene (Holleman, B 20, 3080) Brownish-yellow liquid

IODO-PHENYL-ACRYLIC ACID v IODO CRYNACIC ACID

Ezo-IODO-DI-PHENYL-AMYLIDENE-DIAMINE $C_{12}H_{11}N_2I$ & $C_{12}H_9I(NHPh)_2$ Formed by heating iodo isovalic c aldehyde with aniline (Chautard, A Ch [6] 16, 169) Large brownish yellow needles, v sol water and alcohol, m sol other solvents Decomposed on fusion Forms uncrystallisable salts

DI-IODO-DIPHENYL-DI-CARBOXYLIC ACID $C_{12}H_8I_2O_4$ & $C_{12}H_8I_2(CO_2H)_2$ $C_{12}H_8I_2CO_2H$ [262°] Prepared by the action of HI on the diazo-derivative of di amido di phenyl dicarboxylic acid (Schultz, B 11, 217, A 196, 21, 203, 95) Amorphous, v sl sol boiling water, v sol alcohol, acetone, and ether

DI IODO PHENYLENE OXIDE so called $C_{12}H_8I_2O$ Tetra iodo diphenylene quinone Formed in the action of iodine and KOH upon *o*, *m*, or *p* oxy benzoic acid and on phenol (Lautemann, A 120, 309, Kammerer & Benzing, B 11, 557) Formed also by boiling tri iodo phenol with aqueous $Na_2CO_3(L)$, and by distilling di iodo diphenyl dicarboxylic acid with lime (Schultz, B 11, 217) Reddish brown powder, insol water, alcohol, ether, chloroform, and benzene Dissolves in CS_2 with deep red colour Boiling $KOHAq$ has little action on it Conc HNO_3 forms picric acid It decomposes at 200° Aqueous SO_2 at 100° forms colourless $C_{12}H_8I_2O_2$

DI-EZO IODO-DI-PHENYL-ETHYLENE

$C_{12}H_{10}I_2$ & $C_{12}H_8I_2$ CIPh CIPh Formed by heating di-phenyl acetylene (tolane) with dry iodine and crystallising from chloroform (E Fischer, A 211, 238) Rose coloured plates, v sl sol alcohol Decomposed by heat

DI IODO DI-PHENYL-ETHYLIDENE-DIAMINE $C_{12}H_{11}IN_2$ & $C_{12}H_9I_2(NHPh)_2$ Obtained by heating iodo acetic aldehyde with excess of aniline (Chautard, A Ch [6] 16, 155) Yellow needles or tables Cannot be melted without decomposition V sol alcohol, sol ether, benzene and CS_2 With strong acids it forms uncrystallisable salts, v sol water and alcohol

DI-p-IODO DI-PHENYL-GUANIDINE

$C_{12}H_{11}I_2N_3$ & $CN_2H_2(C_6H_4I)_2$? From *p*-iodo-aniline in ethereal solution and $CyCl$ (Hofmann, A 67, 148) Crystalline— $B_2H_3PtCl_4$

Tri-p-Iodo-tri-phenyl-guanidine $C_{18}H_{15}I_3N_3$ From di *p*-iodo di phenyl thio-urea and iodine (Losanitsch, B 5, 158)

Ezo-IODO-DI-PHENYL-HEPTYLIDENE-DIAMINE $C_{18}H_{19}I_2(NHOC_2H_5)_2$ Formed by heating iodo heptioic aldehyde with aniline (Chautard, A Ch [6] 16, 178) Lemon yellow deliquescent tables, v sol alcohol, sl sol benzene and $CHCl_3$ Decomposes on heating Does not give crystalline salts

p-iodo-phenyl-hydrazine $C_6H_4I.NH_2$, ϵ $C_6H_4I.NH.NH_2$ [10°] Formed, by reducing the diazo-derivative of p-iodo aniline [60°] with an excess of $SnCl_2$ (Neufeld, A 248, 98) Silky needles (from hot water), v sol alcohol, ether, chloroform, benzene, and dilute H_2OAc With acetone it forms $C_6H_4I.N_2H.CMe_2$ crystallising from petroleum ether in white plates [114°] With acetic aldehyde it gives $C_6H_4I.N_2H.CHMe$ [107°] crystallising from petroleum ether in yellow needles

Di-iodo-phenyl-hydrazine $C_6H_3I_2(NH_2)_2$ [4 2 1] [112°] From di-iodo aniline by diazotising and reducing with $SnCl_2$ (Neufeld, A 248, 99) White silky needles, v sol alcohol, ether, and benzene, sl sol hot water and petroleum ether The hydrochloride [162°] crystallises from water in white needles

Di-iodo-s di-phenyl hydrazine $C_6H_4I_2.NH_2$, ϵ [8 1] $C_6H_4I.NH.NH.C_6H_4I$ [1 3] *Hydrazo di-iodo benzene* [90°] Formed by heating the azoxy compound $C_6H_4I.N_2O.C_6H_4I$ with alcoholic ammonium sulphide at 100° (Gabriel, B 9, 1408) V sol ordinary solvents

Di-iodo-s di-phenyl hydrazine [4 1] $C_6H_4I.NH.NH.C_6H_4I$ [1 4] Formed by heating the corresponding azoxy compound with alcoholic ammonium sulphide at 100° (G) Flat needles, decomposed before melting

p-iodo-phenyl oxamic acid $C_6H_4I.NH.CO.CO_2H$ [c 200°] S 072 at 25° Formed by the action of alcoholic potash on the di-iodo di-anilide of oxalic acid (Dyer a Mixer, Am 8, 357) Long white fibres Sol alcohol and ether — BaA' white pp — AgA' white pp — KA' sol hot water

p-iodo-phenyl phthalimide
(1) $C=O$
 $C_6H_4 \begin{matrix} \diagup \\ \diagdown \end{matrix} \begin{matrix} O \\ O \end{matrix}$
(2) $C=N.C_6H_4I$ [227°–228°] Prepared by heating p-iodo aniline with phthalic anhydride (Gabriel, B 11, 2261) Needles V sol C_6H_6 , less sol ether

o-iodo-phenyl propionic acid $C_6H_4IO_2$, ϵ $C_6H_4I.C_2H_4.CO_2H$ *o-iodo hydrocinnamic acid* [103°] Plates (from water) Formed by reduction of o-iodo cinnamic acid (Gabriel a Herzberg, B 16, 2037)

m-iodo-phenyl propionic acid $C_6H_4I.C_2H_4.CO_2H$ *m-iodohydrocinnamic acid* [68°] Colourless plates Formed by reduction of m-iodo-cinnamic acid (Gabriel a Herzberg, B 16, 2039)

p-iodo-phenyl-propionic acid $C_6H_4I.C_2H_4.CO_2H$ *p-iodo hydrocinnamic acid* [141°] White prisms Formed by reduction of p-iodo-cinnamic acid with HI and P (Gabriel a Herzberg, B 16, 2040)

β -iodo-phenyl-propionic acid $C_6H_4I.CH_2.CO_2H$ [120°] Formed by adding fuming $HIaq$ to a concentrated aqueous solution of β oxy phenyl propionic acid (Glaser, A 147, 97) Formed also from cinnamic acid and conc $HIaq$ in the cold (Fittig a Binder, A 195, 188) Small crystals (from CS_2) Decomposed on fusion Boiling with water converts it into HI and cinnamic acid Aqueous Na_2CO_3 gives HI, styrene, and CO_2

o-iodo-di-phenyl-propylidene-di-amine $C_6H_4I_2.N_2$, ϵ $CH_2I.CH_2.CH(NHPh)_2$

Formed by heating β -iodo propionic aldehyde with excess of aniline (Chautard, A Ch [6] 16, 159) Brownish yellow needles or tables, v sol all ordinary solvents Decomposed by heat without previous fusion Gives no crystalline salts

Di-iodo-di-phenyl sulphide $C_6H_4I_2S$, ϵ $(C_6H_4I)_2S$ [139°] Formed by heating di-phenyl sulphide with iodine and iodic acid in sealed tubes Got also from di-amido di-phenyl sulphide by the diazo reaction (Krafft, B 7, 1165) Lamine

p-iodo-phenyl thiocarbimide $C_6H_4I.NCS$ [65°] Formed by the action of iodine on an alcoholic solution of di-p-iodo di-phenyl thio urea (Losantsch, B 5, 158) Crystals

Di-p-iodo-di-phenyl-thio urea $C_6H_4I_2.N_2S$, ϵ $CS(NH.C_6H_4I)_2$ [173°] From p-iodo aniline, alcohol, and CS_2 (Losantsch, B 5, 157) V sol sol alcohol and ether

iodo-iso-phthalic acid $C_6H_4I(CO_2H)_2$ [6 3 1] [204°] Formed by oxidation of iodo-tolyl methyl ketone $C_6H_4MeI.CO.CH_3$ [1 2 5] with CrO_3 (Klingel, B 18, 2701) Fine white needles Sublimable V sol alcohol, acetic acid, and ether, insol cold water

Salts — $A'Ba$ very sparingly soluble fine white needles — $A'Ca$ microscopic needles — $A'Ag$ white crystalline pp — $A'Cu$ green crystalline pp

iodo propane v propyl iodide

Di-iodo-propane $CH_2I.CH_2.CH_2I$ *Propylene iodide* SG 2 249 From propylene and iodine (Berthelot a De Luca, C R 39, 744) From allyl iodide and gaseous HI at -18° (Malbot, C R 107, 114, B [2] 50, 449) Liquid Split up by alcoholic potash into iodine and propylene

Di-iodo-propane $CH_2I.CH_2.CH_2I$ *Tri-methylene iodide* (227°), (169° at 170 mm) SG 2 2681, d_4^{20} 2 5962, n_D^{20} 2 5614 Obtained by heating s di oxy propane (trimethylene glycol) with fuming $HIaq$ at 100° (Freund, M 2, 640) Also from trimethylene bromide, alcohol, and KI (Perkin, jun, C J 51, 12)

Di-iodo-propane $CH_2I.CH_2.CH_2I$ *Allylene dihydro-di-iodide* (148°) SG 2 215 (O), 2 45 (S) Obtained by direct combination of allylene with HI (in conc solution) (Oppenheim, Bl [2] 4, 434, Semenoff, Bl [2] 5, 446) Heavy oil Partly decomposed by distillation, but may be distilled with steam or with any indifferent gas Sl sol alcohol, v sol ether Becomes coloured in air and light Alcoholic potash forms $CH_2I.CI.CH_2$ Ag_2O gives acetone (Sorokin, Z 1871, 264)

iodo-PROPIOLIC ACID $C_3H_4IO_2$, ϵ $ICCO_2H$ *Iodo propargylic acid Iodo-acetylenic carboxylic acid* [140°] Small colourless prisms or glistening needles

Formation — 1 By saponification of the ethyl ether — 2 By the action of a solution of iodine in KI upon the cuprous compound of calcium or barium propargylate

Reactions — It combines with HBr to form brom-iodo acrylic acid [96°], with HI it yields di-iodo acrylic acid [133°], with bromine dissolved in chloroform it yields di-bromo-iodo-acrylic acid [147°], with an ethereal solution of iodine, tri-iodo-acrylic acid [207°], and with iodine bromide, bromo-di-iodo acrylic acid [182°].

On the other hand, an aqueous solution of bromine converts it into di-bromo iodo ethylene IBrC CHBr with evolution of CO_2 .

Salts— A^+K^- small glistening very hygroscopic needles— A^+Ag^- white pp, decomposed by warming with water forming AgI — A^+Ba^- easily soluble amorphous solid— A^+Cu^-

Ethyl ester A^+Et^- [68°], large colourless prisms Formed by the action of a solution of iodine in KI upon the cuprous compound of propargylic ether (Baeyer, *B* 18, 2274, Homolka a. Stolz, *B* 18, 3282, 19, 536)

α -IODO PROPIONIC ACID $\text{C}_3\text{H}_5\text{IO}_2$, \pm

$\text{CH}_3\text{CHI CO}_2\text{H}$ Prepared by digesting syrupy lactic acid (1 mol) with PI_2 (1 mol), pouring the product into water and extracting with ether (Wichelhaus, *A* 144, 352) Oil, nearly insol water

β -Iodo-propionic acid $\text{CH}_3\text{I CH}_2\text{CO}_2\text{H}$ [82°]

Formation—1 By the action of iodide of phosphorus on glyceric acid (Beilstein, *A* 120, 226, 122, 366, Erlenmeyer, *A* 191, 284)—2 From acrylic acid and conc HIAg (Wislicenus, *A* 166, 1)

Preparation—The product of the oxidation of glycerin with nitric acid is evaporated on the water-bath, and the syrupy residue diluted with water until it possesses S.G. 1.26 This solution (30 c c) is then poured into a flask containing iodine of phosphorus prepared from iodine (50 g) and yellow phosphorus (6.5 g) After the vigorous action has taken place, the solid residue is recrystallised from water (V Meyer, *B* 19, 3294, 21, 24)

Properties—Colourless laminae, v sol hot, v sl sol cold, water, v e sol alcohol and ether May be converted into propionic acid by HI or by sodium amalgam (Moldenhauer, *A* 131, 328) By boiling with water it is converted into hydroacrylic acid and a little acrylic acid Boiling with water and Ag_2O forms hydroacrylic acid, para adipic acid $\text{C}_6\text{H}_{10}\text{O}_4$, dihydroacrylic acid $\text{C}_4\text{H}_6\text{O}_3$, and paracrylic acid $\text{C}_4\text{H}_6\text{O}_2$ [69°] (Beilstein, Wislicenus, *Z* [2] 4, 683, Socloff, Klumenko, *Bl* [2] 34, 321, v also ACRYLIC ACID) β -Iodo propionic acid is converted into adipic acid by heating with reduced silver (W) AgNO_3 gives in an aqueous solution of β iodo propionic acid an immediate pp of AgI

Methyl ether MeA^+ (188°) S.G. 1.841 (Henry, *C* R 100, 114) Colourless oil, turning brown in light Is not pungent Formed from the acid, alcohol, and H_2SO_4

Ethyl ether EtA^+ (202°) (Fittig a. Wolff, *A* 216, 128) S.G. \pm 1.707 (Henry) Formed by heating an alcoholic solution of the acid after adding a few drops of H_2SO_4 Formed also by dissolving the acid (1 pt) in alcohol (3 pts) and saturating with HCl , the yield is only 50 p c, for much EtI is evolved (Lewkowitsch, *J pr* [2] 20, 167; Wichelhaus, *B* 1, 25, Wislicenus, *A* 192, 129) Oil Partly decomposed on distillation

Amide $\text{CH}_3\text{I CH}_2\text{CONH}_2$ [101°] Formed by the action of aqueous NH_3 on the methyl ether in the cold (Henry) Colourless tables, turning yellow in light V sol water Its solution gives a pp. with AgNO_3

β -IODO PROPIONIC ALDEHYDE

$\text{CH}_3\text{I CH}_2\text{CO H}$ S.G. 1.221 Prepared by the action of iodine (25 g.) and iodic acid (10 g) on propionic aldehyde (18 c c) diluted with alcohol

(50 c c) It is washed with KOH solution and poured into water (Chautau d, *A Ch* [6] 16, 157).

Properties—Heavy colourless liquid, not inflammable, with an exceedingly irritating vapour Miscible with alcohol, ether, and acetone, sl sol water Is totally decomposed at 100° Very dilute solutions of KOH , NaOH , or NH_4HO attack it slowly in the cold Conc solutions resinify it Mineral acids behave similarly HNO_3 oxidises it to $\text{CH}_3\text{I CH}_2\text{CO}_2\text{H}$ [82°] $\text{Ag}(\text{C}_2\text{H}_5\text{O}_2)$ forms propyl acetate (90°) AgCN and silver sulphocyanide give $\text{CH}_2(\text{CN})\text{CH}_2\text{CO H}$ and $\text{CH}_2(\text{CNS})\text{CH}_2\text{CO H}$ Aniline gives the compound $\text{CH}_3\text{I CH}_2\text{CH}(\text{N}^+\text{C}_6\text{H}_5)_2$.

IODO PROPYL ALCOHOL v Iodhydrin of PROPYLENE GLYCOL

Di iodo-propyl alcohol $\text{C}_3\text{H}_5\text{I}_2$, \pm
 $\text{CH}_3\text{I CHI CH}_2\text{OH}$ *Di iodide of allyl alcohol* [45°] Prepared by dissolving iodine in allyl alcohol (Hubner a. Lellmann, *B* 13, 460, 14, 207) Colourless needles Easily decomposed by light or heat Sol alcohol, ether, and benzene, insol water On heating the chloroform solution it gives a compound crystallising in colourless prisms [160°], which is probably an iodo allyl alcohol

Di iodo isopropyl alcohol $\text{CH}_3\text{I CH}(\text{OH})\text{CH}_2\text{I}$
Glycerin di iodhydrin [α - 18°] S.G. 1.24 Prepared by heating the dichlorhydrin of glycerin with KI and water on a salt bath (Nahmacher, *B* 5, 353, Claus, *A* 163, 24) Faintly yellowish oil Decomposes when distilled

p-IODO PROPYL-BENZENE $\text{C}_6\text{H}_4(\text{C}_2\text{H}_4)\text{I}$ [14] [250°] Formed by heating p diazo propyl benzene with HI (Louis, *B* 16, 110) Volatile with steam Colourless oil Sol ether, m sol alcohol, almost insol water On oxidation with cold CrO_3 in acetic acid it gives p iodo benzoic acid

p Iodo iso propyl benzene $\text{C}_6\text{H}_4(\text{C}_2\text{H}_4)\text{I}$ (234°) Prepared by heating p diazo iso propyl benzene with HI (Louis, *B* 16, 114) Colourless oil On oxidation it gives p iodo benzoic acid

α -IODO PROPYLENE v ALLYL IODIDE

α Iodo propylene $\text{CH}_3\text{CHI CH}_2$, *Allylene hydro iodide* (82°) (S), (93°-103°) (O) S.G. 1.835, 1.803 Formed by decomposing di iodo propane $\text{CH}_3\text{CI}_2\text{CH}_2$ (1 mol) with alcoholic KOH (1 mol), and mixing the distillate with water (Semenoff, *Bl* [2] 5, 446, *Z* 1865, 725, Oppenheim, *Bl* [2] 4, 434, *Z* 1865, 719)

Di iodo propylene $\text{C}_3\text{H}_4\text{I}_2$, \pm $\text{CH}_2\text{CI CHI CH}_2$ *Allylene di iodide* (198°) Obtained by exposing allylene for two months to a solution of I in aqueous KI in sunshine (Oppenheim) Oil. Turns brown in light Yields allylene iodo alcohol KOAc

Tri iodo propylene $\text{CHI CI CH}_2\text{I}$ *Di iodo-allyl iodide Propargyl tri iodide* [41°] Formed by the combination of propargyl iodide with iodine (Henry, *B* 17, 1132) Small colourless needles

Tri iodo-propylene $\text{CH}_2\text{CI CI}_2$ *Iodo-allylene di iodide* [64°] From silver allylene and iodine in ethereal solution (Liebemann, *A* 135, 273) Needles Decomposes at 78° V e sol ether, m sol alcohol. Alcoholic potash gives iodo-allylene

IODO-PROPYLENE-GLYCOL v Iodhydrin of GLYCERIN.

IDO-PROPYL-THIOPHENE C_8H_7S \approx C_8H_7S C_8H_7 . From α propyl thiophene (Rufen, B. 20, 1743) Oil, volatile with steam

Ido-IDO PYROTARTARIC ACID $C_8H_7IO_4$ [185°] From itaconic acid an¹ HI at 150° (Swarts, Z 1866, 722) Nodules Reduced by further treatment with HI to pyrotartaric acid

TETRA IODO PYRROLE C_4I_4NH 'Iodol' S 02, S (90 p.c. alcohol) 6 at 15°, S (ether) 60 Formed by the action of an ethereal solution of iodine on pyrrole potassium (Ciamician a Dennstedt, G 13, 18, B 15, 2582), and by the action of iodine on an alkaline solution of pyrrole (Ciamician a Silber, G 16, 543, B 18, 1766) Long yellowish brown flat prisms or minute yellow needles (from dilute alcohol) Sol ether, acetic acid, and hot alcohol, nearly insol cold alcohol, insol water and aqueous acids Decomposes at about 140°-150° Gives a white ppt with Ag_2O , instantly blackening, green colouration with $HgCl_2$. Has no basic properties It is not decomposed by boiling water, but boiling HCl aq blackens it It does not dissolve in aqueous KOH, but alcoholic potash dissolves it forming a potassium derivative which is decomposed by acids (even CO) but not by water Zinc dust and KOH reduce it to pyrrole (Ciamician a Silber, B 19, 3027) When heated gently with conc H_2SO_4 it gives at first a green, then a dirty violet colouration Its alcoholic solution gives a red colour with nitric acid (Vulpinus) It is employed pharmaceutically as a substitute for iodoform for suppurating sores, fungoid growths, hay fever, &c, having the advantage of possessing no odour, and exerting no poisonous effect upon the system

IDO-QUINOLINE C_8H_5IN [63°] (above 300°) SG 1.93 Prepared by heating quinoline with a KI solution of iodine and HIO_4 (La Coste, B 13, 780) Monoclinic prisms, or long thin needles. Easily volatile with steam

Salts - $B'HCl$ aq small yellow needles - $B'H PtCl_2$ 2aq long orange needles, sl sol water - $B'H C_2O_4$, sparingly soluble yellow needles or plates

Methylo iodide $B MeI$ glistening golden plates, sol hot water v sl sol cold water and alcohol, insol ether

Methylo chloride $B' MeCl$ aq fine yellowish needles or thick yellow prisms, dimorphous (Lehmann, Z K 12, 377), v sol water - ($B' MeCl$), $PtCl_4$ fine orange crystals, sl sol cold water

(Py 3) Iodo quinoline C_8H_5 $\begin{matrix} CH \\ | \\ N \\ | \\ Cl \end{matrix}$ [53°]

Formed by heating (Py 3) chloro quinoline with HI (Friedlander a Weinberg, B 18, 1531) White needles Sl sol water, v sol other solvents - BHI long needles - $B'H_2Cl_2PtCl_4$ aq red needles

Di-iodo-quinoline $C_8H_4I_2N$ [90° uncor] Formed by the action of iodine in CS_2 on quinoline (Claus a Istel, B 15, 824), Dull-green metallic needles Sol alcohol, ether, and acetic acid

DI IODO-QUINONE $C_6H_4I_2O_2$ [159°] Formed by the action of iodic acid on the diacetyl derivative of hydroquinone (Metzler, B 21, 2555) Yellow needles (from alcohol) Is converted by

the action of sulphurous acid into the hydroquinone [142°]

Di iodo quinone $C_6H_2I_2O_2$ [3541] [180°] From di-iodo p amido-phenol (q v), H_2SO_4 , and $K_2Cr_2O_7$ (Seiffert, J pr [2] 28, 438) Formed also by oxidising di iodo phenol sulphonic acid with CrO_3 (Kehrmann, J pr [2] 37, 336) Golden plates (from benzoline) Readily sublims, almost insol cold, v sl sol boiling water With HCl and $SnCl_2$ it gives di iodo hydroquinone [145°] $FeCl_3$ reconverts this into di-iodo quinone

Di iodo quinone chlorimide $C_6H_2I_2$ $\begin{matrix} <O \\ | \\ NCl \end{matrix}$ [123°] From $C_6H_4I_2(NH_2)(OH)$, hydric chloride, and bleaching powder solution (Seiffert, J pr [2] 28, 438) With NMe_3 it gives

$C_6H_2I_2$ $\begin{matrix} <O \\ | \\ N \end{matrix}$ $>C_6H_4NMe_2$

IDO RESORCIN $C_6H_4IO_2$ \approx $C_6H_4I(OH)_2$ [67°] Formed by agitating an ethereal solution containing resorcin (10 pts) and iodine (24 pts) with PbO (110 pts), distilling off the ether and recrystallising from benzene (Stenhouse, C N 26, 279, A 171, 311). Trimetric prisms, sol water

Tri iodo resorcin $C_6H_3I_3(OH)_2$ [145°] (M a N), [154°] (C) Formed, together with a brown substance insoluble in CS_2 , when ICl is added to an aqueous solution of resorcin (Michael a Norton, B 9, 1752) Formed also by adding an aqueous solution of resorcin to a solution of KIO_3 , iodine, and KI (Claassen, B 11, 1443). Prepared by adding bleaching powder to a dilute alkaline solution of resorcin (1 mol) and KI (7 mols), and then acidifying (Degener, J pr [2] 20, 324) Needles (from CS_2), sl sol hot water, v sol alcohol and ether May be sublimed. Boiling HNO_3 gives tri nitro resorcin

Di acetyl derivative $C_6H_3I_3(OAc)_2$ [170°] Needles, v sol alcohol and ether

IDO RESORCIN SULPHONIC ACID $C_6H_3I_3(OH)_2(SO_3H)$ From potassium resorcin sulphionate and iodine (H Fischer, M 2, 340) - KA' 3aq minute crystals

Iodo resorcin disulphonic acid $C_6H_2I_3(OH)(SO_3H)_2$ Formed by digesting potassium resorcin disulphonate (30 g) with iodine (33 g) in dilute alcoholic solution at 100° (F) - KA long needles

IDO SALICYLIC ACID v Iodo o oxy-BENZOID ACID

IDO STEARIC ACID $C_{18}H_{33}IO_2$ From di oxy stearic acid and HI (A Saytzeff, J pr [2] 33, 309) Oil

Iodo stearic acid $C_{18}H_{33}IO_2$ From oleic acid, PI_3 , and a little water The product is mixed with water and extracted with ether (M C a A Saytzeff, J pr [2] 35, 384)

Properties - Oil Resembles the preceding acid

Reactions - 1 Reduced by Zn and HCl to stearic acid - 2 Moist Ag_2O forms a substance that is unsaturated (taking up 55 p.c I from its solution in $HgCl_2$ aq), but is converted by alcoholic KOH into oxy stearic acid - 3 Alcoholic KOH forms solid iso oleic acid [45°], and also ordinary oleic acid

Iodo-stearic acid $C_{18}H_{33}IO_2$ Formed by heating iso oleic acid with tri iodide of phosphorus and water (Coust a Saytzeff, J pr [2] 37, 276, Bk [2] 47, 169) Oil, sol ether.

Reactions—1. Yields an oxy stearic acid [85°] on treating with silver oxide—2 Alcoholic potash regenerates iso-oleic acid [40°-45°], but forms no oleic acid—3 Alkaline KMnO_4 oxidises it to di-oxy-stearic acid [78°]

IODO-STEARIDENIC ACID $\text{C}_{18}\text{H}_{33}\text{IO}_2$ *Iodo-oleic acid* From ricinoleic acid $\text{C}_{18}\text{H}_{33}\text{O}_2$, water, P, and iodine at 100° (Claus, B 9, 1917) Oil Reduced by boiling with zinc and HClAg to stearic acid Combines with bromine

DI-IODO-SUCCINAMIC ACID

$\text{CO}_2\text{HCH}_2\text{CH}_2\text{CONH}_2$

Ethylether A'Et [134°], long needles, slightly soluble in cold water Formed by the action of iodine upon diazo succinamic ether $\text{CO}_2\text{EtCH}_2\text{CH}_2\text{ON}_2$ in ethereal solution (Curtius & Koch, B 19, 2462, J pr [2] 38, 485)

IODO-TARCONINE v NARCOTINE

IODO-THIENYL METHYL KETONE

$\text{C}_6\text{SH}_4\text{COCH}_3$ *Iodo-acetothienone* [129°] Formed by the action of acetyl chloride upon mono- or di iodo thiophene in presence of AlCl_3 (Gattermann & Römer, B 19, 692) Long colourless needles (from alcohol) Very volatile with steam Strong odour By alkaline KMnO_4 it is oxidised to iodo thiophene carboxylic acid [131°]

Phenyl hydrazide $\text{C}_6\text{SH}_4\text{C(NHPh)CH}_3$ [134°], yellow tables, sl sol alcohol

(a) IODO-THIOPHENE $\text{C}_4\text{H}_3\text{IS}$: s

$\text{CHCH} \rangle \text{S}$ (182° cor). Oil Formed by the action of iodine and HgO on thiophene at the ordinary temperature (Meyer & Kreis, B 17, 1558, Egh, B 18, 544) With sodium and EtI it gives ethyl thiophene With Na and n butyl bromide it forms n -butyl thiophene (182°) Gives an iodo-nitro thiophene [74°] (Kreis, B 17, 2078)

Di-iodo-thiophene $\text{C}_4\text{H}_2\text{I}_2\text{S}$ [40½°] White crystals Formed by the action of 2 mols of iodine and HgO on thiophene at the ordinary temperature (Meyer & Kreis, B 17, 1558)

IODO-THIOPHENE CARBOXYLIC ACID

$\text{C}_6\text{SH}_4\text{I(COOH)}$ *Iodo thiophenic acid* [131°] Formed by oxidation of iodo thienyl methyl ketone with alkaline KMnO_4 (Gattermann & Römer, B 19, 693) Colourless silky needles (from water) Sublimes in glistening tables— $\text{NH}_4\text{A'}$ needles, sl sol cold water

(a)-IODO-THIOPHENE-(β)-DI SULPHONIC ACID $\text{C}_4\text{HIS(SO}_3\text{H)}_2$ Formed by sulphonation of (a)-iodo thiophene On reduction with sodium amalgam it yields thiophene (β) di sulphonic acid (Langer, B 18, 559)

IODO-THIOXENE is IODO DI METHYL THIOPHENE (q v)

IODO-THYMOL $\text{C}_{10}\text{H}_7\text{MePr(OH)I}$ [1436] [69°] Prepared by adding iodine (8 g) to a solution of thymol (5 g) in ammonia (6 cc) mixed with alcohol (2 cc) and distilling the only product with steam (Willgerodt & Kornblum, J pr [2] 39, 289) Lustrous white needles, insol water, sol other solvents Oxidised by MnO_2 and H_2SO_4 or by FeCl_3 to thymoquinone Not attacked by aqueous KOH at 800° HNO_3 forms nitro thymol, displacing I by NO_2 H_2SO_4 forms a sulphonic acid.

Ethyl derivative $\text{C}_{12}\text{H}_{15}\text{MePrI(OEt)}$ [52°] Opaque white rimetric tables, insol cold water, sl sol hot water and alcohol

Acetyl derivative $\text{C}_{12}\text{H}_{15}\text{MePrI(OAc)}$

[71°] White needles

Benzoyl derivative $\text{C}_{12}\text{H}_{15}\text{MePrI(OBz)}$

[95°] Large tables

Acryl derivative [155°], yellowish crystalline aggregates

IODO THYMOL SULPHONIC ACID

$\text{C}_{10}\text{HMePr(OH)ISO}_3\text{H}$ [14326] From thymol by successive sulphonation and iodation (Kehrmann, J pr [2] 39, 392) Gives an iodo thymoquinone on oxidation HNO_3 gives di nitro thymol [53°]— KA'2aq crystals melting in water of crystallisation at 80°, decomposed at 120°— BaA' — AgA'

IODO-THYMOQUINONE $\text{C}_{10}\text{HMePrIO}$ [52641] [61°] Formed by oxidising iodo-thymol sulphonic acid with CrO_3 (Kehrmann, J pr [2] 39, 392) Yellowish red prisms Reduces to an iodo hydrothymoquinone [74°]

Oxim $\text{C}_{10}\text{HMePrIO(NOH)}$ [52641] [130°] Formed by heating the quinone with hydroxylamine hydrochloride in diluted (75 p c) alcoholic solution Long yellow prisms and needles, sol alcohol and ether, insol cold water Its acetyl derivative $\text{C}_{10}\text{HMePrIO(NOAc)}$ crystallises in golden needles [70°] Its sodium derivative crystallises in greenish laminae

Iodo thymoquinone $\text{C}_{10}\text{HMePrIO}$ [52341] [66°] From iodo carvacrol sulphonic acid by oxidation with chromic acid mixture (Kehrmann, J pr [2] 40, 188) Garnet red tables, sol alcohol and ether More volatile with steam than its isomeride Smells like quinone Hydroxylamine slowly forms an oxim

o IODO-TOLUENE $\text{C}_6\text{H}_4\text{I}$: s $\text{C}_6\text{H}_4\text{ICH}_3$ [21] (205°) (B & K), (211° V) (K) S.G. 2.1697 (B & K) Formed from o toluidine by the diazo reaction (Beilstein & Kuhlberg, Z 8, 102, A 158, 347, Kekulé, B 7, 1007, Mabery & Robinson, Am 4, 101) Oil

Reactions—1 Oxidised by dilute nitric acid to o iodo benzoic acid [157°]—2 With ClCOEt and Na it forms $\text{C}_6\text{H}_4\text{MeCOEt}$ —3 CrO_3Cl gives $\text{C}_6\text{H}_4\text{ICHCl}$, and a little $\text{C}_6\text{H}_4\text{ICH}_3$ (Stuart & Elliott, C J 53, 805)—4 When heated with H_2SO_4 it forms iodo toluene sulphonic acid, di iodo toluene, and tri iodo toluene (Neumann, A, 241, 62)

m Iodo toluene $\text{C}_6\text{H}_4\text{ICH}_3$ [31] (204°) S.G. 2.1698 From *m* toluidine by the diazo reaction (B & K)

p Iodo-toluene $\text{C}_6\text{H}_4\text{ICH}_3$ [41] [35°] (2115°) From *p* toluidine by the diazo-reaction (Körner, Bull Acad Belg 1867, 157) The same body appears to be formed from mercury ditolyl and iodine, although the melting point is given as 20° (Dreher & Otto, A 154, 171) Laminae May be sublimed Gives *p* iodo benzoic acid when oxidised by chromic acid mixture H_2SO_4 forms iodo-toluene sulphonic acid and di- and tri-iodo-toluene (Neumann, A, 241, 58)

m-Iodo-toluene v BENZYL IODIDE.

o-IODO-TOLUENE SULPHONIC ACID

$\text{C}_6\text{H}_4\text{ISO}_3\text{H}$: s $\text{CH}_3\text{C}_6\text{H}_4\text{SO}_3\text{H}$ From o-iodo-toluene and SO_3 (Mabery & Palmer, Am 6, 170) Syrupy liquid— BaA' , 1½ aq : needles— CaA' , 2½ aq— PhA' , 2 aq

***p*-Iodo-toluene (a)-sulphonic acid**

$\text{CH}_3\text{C}_6\text{H}_4\text{I}\text{SO}_3\text{H}$ Formed, together with the (B) isomeric, by gradually adding *p* iodo toluene to SO_3 , both dissolved in chloroform (Glassner, B 8, 560) — BaA'_4 4aq needles, ν e sol water

***p* Iodo toluene (B)-sulphonic acid**

$\text{CH}_3\text{C}_6\text{H}_4\text{I}\text{SO}_3\text{H}$ Formed as above Deliquescent crystalline mass — KA'_4 4aq very soluble laminæ — NaA'_4 4aq dense aggregates of whetstone shaped very soluble crystals — CaA'_4 3aq very soluble silky needles — $\text{3aA}'_4$ 4q thin laminæ, sl sol water — CuA'_4 6aq light blue needles, ν sol water

Amide $\text{C}_6\text{H}_4\text{MeI}\text{SO}_2\text{NH}$ [179°] Crystals, m. sol hot water, ν so alcohol

Iodo-toluene disulphonic acid

$\text{C}_6\text{H}_3\text{MeI}(\text{SO}_3\text{H})_2$ [143°]

From $\text{C}_6\text{H}_5\text{Me}(\text{NH}_2)(\text{SO}_3\text{H})_2$ by diazo-reaction (E Richter, A 230, 325, Limpriicht, B 18, 2170) Slender white needles, ν sol alcohol and water — BaA''_4 6aq prisms, ν sol water — KA''_4 2aq small prisms

Chloride $\text{C}_6\text{H}_4\text{MeI}(\text{SOCl})_2$ [143°] After one fusion it melts at 126° Long white prisms, sl sol ethe-

Amide [130°-132°] White needles (from water)

***p*-IODO-*o*-TOLUIDINE** $\text{C}_6\text{H}_3\text{MeI}(\text{NH}_2)$ [142°]

[49°] (273°) From iodo *o* nitro toluidine by reduction (Heynemann, Z [2] 6, 402, A 158, 338) Needles Boils, with rapid decomposition, at 273° ν e sol alcohol, ether, and CS_2 — $\text{B}'\text{HNO}_3$ colourless nacreous laminæ S 95 at 16°

Iodo-toluidine $\text{C}_6\text{H}_4\text{MeI}(\text{NH})$ [143°] [189°] From *p* iodo toluene by nitration and reduction (Glassner, B 8, 561) Needles or plates, ν sol alcohol — $\text{B}'\text{HCl}$ needles — $\text{B}'\text{HNO}_3$ plates — $\text{B}'\text{H}_2\text{SO}_4$ needles

Di-iodo-*p*-toluidine $\text{C}_6\text{H}_3\text{MeI}_2(\text{NH}_2)$ [1354°]

[1245°] Formed by the action of ICl on *p* toluidine dissolved in HClAq (Michael a Norton, B 11, 115, Am 1, 263) Ramified groups of slender needles, m sol cold alcohol, sl sol hot water

IODO-TOLUIDINE SULPHONIC ACID

$\text{C}_6\text{H}_3\text{Me}(\text{NH})\text{I}(\text{SO}_3\text{H})$ [1245°] From the diazo derivative of $\text{C}_6\text{H}_3\text{Me}(\text{NO}_2)(\text{NH}_2)(\text{SO}_3\text{H})$ [1245°] and conc HI at 140° (Limpriicht a Foth A 230, 308, B 18, 2185) Satiny needles (containing aq) Sl sol cold water, m sol hot water — BaA''_4 trimetric tables, ν sol water

IODO-TOLUQUINONE $\text{C}_6\text{H}_3\text{MeI}_2$ [6241°]

[117°] Formed by oxidising a solution of iodo cresol sulphonic acid in sulphuric acid with chromic acid (Kehrmann, J pr [2] 37, 340, 39, 392) Long reddish yellow needles, m sol ether Reduced by stannous chloride to iodo hydrotoluquinone [111°] With hydroxylamine it gives the mono-oxim crystallising in short yellow prisms [156°]

Di-iodo-toluquinone $\text{C}_6\text{H}_3\text{MeI}_2\text{O}_2$ [36241°]

[118°] From di iodo *m* cresol sulphonic acid and CrO_3 (Kehrmann, J pr [2] 39, 392) Garnet-red laminæ, ν sol organic solvents May be sublimed

DI-IODO-DITOLYL [341°] $\text{C}_6\text{H}_3\text{MeI}\text{C}_6\text{H}_4\text{MeI}$ [134°] [100°]. From di amido ditolyl by Sandmeyer's modification of the diazo-reaction (Stolle, B. 21, 1096) Yellow needles

***o*-IODO-DI-TOLYL-ETHYLIDENE-DI-AMINE** $\text{CH}_3\text{CH}(\text{NH}_2)\text{CH}_2(\text{Me})_2$ Obtained by

heating iodo acetic aldehyde with *p*-toluidine (Chautard, A Ch [6] 16, 156) Orange yellow prisms or tables, decomposed by heat Does not furnish crystalline salts

IODO TOLYL METHYL KETONE

$\text{C}_6\text{H}_4\text{MeI}\text{COCH}_3$ [125°] [89°] Formed by heating diazo tolyl methyl ketone (from amido-tolyl methyl ketone [102°]) with an excess of HI (Klingel, B 18, 2700) Yellowish prisms ν sol alcohol and ether, sl sol ligroin and benzene, insol water By CrO_3 it is oxidised to iodo iso phthalic acid [204°]

 β IODO-VALERIC ACID $\text{C}_6\text{H}_4\text{IO}_2$ 12

$(\text{CH}_3)_2\text{CI}\text{CH}_2\text{CO}_2\text{H}$ [80°] Solidifies at 59° Separates as crystals when HI is passed into a concentrated solution of β oxy isovaleric acid (Schirokoff, J pr [2] 23, 285) Converted by sodium amalgam to isovaleric acid

Iodo valeric acid $\text{C}_6\text{H}_4\text{MeI}\text{CO}_2\text{H}$ (?) **Hydro-iodide of tiglic acid** [865°] Formed by the combination of tiglic (methyl crotonic) acid with HI which may be effected in the cold (Schmidt a Berendes, A 191, 117) Formed also, together with the following, when angelic acid is heated with HIAq (Schmidt, A 208, 254) Needles, sl sol cold water, decomposed by boiling with water Converted by zinc and dilute H_2SO_4 into $\text{C}_6\text{H}_4\text{MeH}\text{CO}_2\text{H}$ Aqueous AgNO_3 gives AgI , tiglic acid and CO_2

Iodo valeric acid $\text{CH}_3\text{CHI}\text{CHMe}\text{CO}_2\text{H}$ [46°] **Hydro iodide of angelic acid** From angelic acid and conc HIAq in the cold (Fittig, A 216, 162) Prisms, ν sol water Zinc and dilute H_2SO_4 converts it into $\text{C}_6\text{H}_4\text{MeH}\text{CO}_2\text{H}$ Aqueous AgNO_3 gives AgI , tiglic acid, and CO_2 Aqueous Na_2CO_3 at 0° gives CO_2 , ψ butylene $\text{CH}_3\text{CHCHCH}_3$, and HI ν also Angelic acid, vol 1 p 266

IODO-ISOVALERIC-ALDEHYDE $\text{C}_6\text{H}_4\text{IO}_2$ 12

$(\text{CH}_3)_2\text{CH}\text{CHI}\text{CHO}$ (?) SG 1217

Preparation — Isovaleric aldehyde (24 cc) dissolved in alcohol (50 cc) is treated with iodine (20 g), and iodic acid (8 g) The reaction takes place at the ordinary temperature, and is complete in about 15 days The liquid is poured into excess of water, and decolourised by alkali or reduced silver (Chautard A Ch [6] 16, 160).

Properties — Colourless liquid, blackening on exposure to light, and having an extremely irritating and suffocating odour It is completely decomposed at 100°, and is not solidified at -70° ν sol alcohol and ether, less sol benzene, CHCl_3 , and CS Sl sol water

Reactions — Rapidly decomposed by alkalis. The action of ammonia is complex, giving valeric aldehyde ammonia, valeridine $\text{C}_6\text{H}_4\text{N}$, and valentrine $\text{C}_6\text{H}_4\text{N}$ Forms a crystalline compound with NaHSO_4 $\text{Ag}(\text{C}_6\text{H}_4\text{O}_2)$ at 100° yields amyl acetate (138°) AgCN and AgSCN react forming AgI and the corresponding derivatives. Forms a mono- and a di anilide with aniline.

IODO-VANILLIN *o* Methyl derivative of**IODO-DI OXY-BENZEOIC ALDEHYDE****DI-IODO-VINYL-AMINE** $\text{Cl}_2\text{CH}(\text{NH}_2)$ [192°

with decomposition] Formed by the action of cold aqueous NH_3 , CO_2 and alcohol being eliminated upon the di iodo oxy acrylic ether $\text{Cl}_2\text{C}(\text{OH})\text{CO}_2\text{Et}$, obtained by treating diazo-oxy acrylic ether $\text{CN}_2\text{C}(\text{OH})\text{CO}_2\text{Et}$ with an ethereal solution of iodine (Buchner a Curtius, B. 19, 851) Small yellowish prisms. Very

sparingly soluble in cold water and ether, more easily in hot water and hot alcohol. Volatile with steam. It is stable towards acids, but alkalis set free NH_3 in the cold.

Di- α -iodo- α -xylene $\text{C}_8\text{H}_6(\text{CH}_2\text{I})_2$, *o*-Xylyl *ene-iodide* [110°]. Prismatic crystals. Formed by heating phthalyl alcohol (di- α -oxy-xylene) with HI (Lesser, B 17, 1826).

Di- α -iodo- p -xylene $\text{C}_8\text{H}_6(\text{CH}_2\text{I})_2$, [α 170°]. Obtained by boiling [41] $\text{C}_8\text{H}_6(\text{CH}_2\text{OH})_2$ with conc HIAq for a few minutes (Grimaux, Z 1870, 835). Slender needles, sl sol ether, v sol boiling alcohol and chloroform. Turns yellow in air. Not very volatile with steam.

iodoplumbic acid H_2PbI_4 , v **LEAD**, **iodide of, Combinations**, No 3.

IONS. The elements or radicals into which a compound is primarily separated by electrolysis (v **PHYSICAL METHODS**, section *Electrical methods*).

IPECACUANIC ACID $\text{C}_8\text{H}_7\text{O}_5$. An acid existing, according to Willkg (A 76, 342), along with emetine (*q v*) in the root of *Cephaelis Ipecacuanha*. It is extracted by boiling alcohol, ppd. by basic lead acetate, and the pp decomposed by H_2S . Reddish brown, very bitter, amorphous mass, m sol ether, v sol alcohol and water. Colours ferric salts green, the colour being changed to violet by ammonia. Its dilute solution does not ppt $\text{Pb}(\text{OAc})_2$, but ppts basic lead acetate. Its alkaline solution absorbs oxygen from the air. It thus somewhat resembles gallic acid. Podwysotzky (*Ph* [3] 10, 642) by extracting ipecacuanha with ether and light petroleum obtained an acid ('Erythrocephalein'), which formed a purple red alkaline salt, and which crystallised from chloroform in coloured needles.

IPEOMIC ACID $\text{C}_8\text{H}_7\text{O}_5$, [104°]. Produced by the action of nitric acid on jalapin (Mayer, A 85, 143, Poleck a Samelson, C C 1884, 813). Resembles sebacic acid.

IRIDIUM Ir. At w 192.5 Mol w un known [2200°] (Van der Weyde), [1950°] (Viole, C R 89, 702), [2500°] (Pictet, C R 88, 1317) SG 22.42 at 17.5° (Deville a Debray, P M [4] 50, 651) SH 0°-100° = 0.323, 0°-1400° = 0.401 (Viole, C R 89, 702) CE linear 000007 (Fizeau, C R 68, 1125).

Occurrence—As metal, alloyed with Pt, Os, Ru, Rh, and Pd. Specimens of platinum-iridium, osmium-iridium, &c, contain from 25 to 78 p.c. Ir (v Deville a Debray, A Ch [3] 56, 431, Berzelius, P 13, 435, 527, 15, 208). In 1802 Tennant (*T* 1804 411) noticed a metallic residue when he dissolved Pt ore in *aqua regia*, this residue was examined by Descotils (Gehlen's *Journ Chem* 2, 273), and Fourcroy a Vauquelin (Gehlen's *Journ Chem* 3, 362). In 1804 Tennant (*lc*) showed that the residue contained two new metals, to one he gave the name *Iridium* because of the varied colours of its oxides, and to the other the name *Osmium* because of the peculiar smell of its volatile oxide.

Formation—1 By digesting Ir_2O_3 or IrCl_3 with formic acid—2 By action of sunlight on an alcoholic solution of Ir sulphate.

Preparation—When Pt ore is heated with *aqua regia* osmium and platinum-iridium remain as black insoluble scales. Ir is prepared from the residue by various methods. 1 W von

Schneider (*A. Suppl* 5, 261) mixes the insoluble in *aqua regia* with N_2Cl , and heats to low redness in a stream of Cl_2 , Os is thus removed. The residual mixed chlorides are triturated with the smallest possible quantity of water, and then washed on to a filter, the solution is treated with Cl_2 mixed with a little HClAq , and shaken up with excess of KCl , the pp is washed with water, and then with saturated KClAq . The pp is now nearly pure K_2MCl_6 , $\text{M} = \text{Ir, Ru, and Pt}$. The pp is dissolved in much boiling water, and H is passed in for several days (the flask being closed by a caoutchouc cork) until the supernatant olive-green liquid treated with potash becomes colourless and then blue or turbid. Pt and Ru are thus wholly ppd as tartrates, and most of the Ir remains in solution as IrCl_3 . H is removed by a stream of CO_2 —otherwise explosions occur on opening the flask from the action of the ppd Pt and Ru on the H and O in the flask—the corks are removed, and the liquid is again saturated with H, Ir is ppd on the surface of the liquid in large lustrous laminae—2 Matthey (*Pr* 28, 463) prepares Ir free from all metals except Pt as follows. Ordinary Ir, finely divided, is fused with 10 times its weight of Pb, the Pb is dissolved in HNO_3Aq , and the insoluble is digested for a long time with *aqua regia*, the insoluble is fused with KHSO_4 (to remove Rh), and then melted with 10 times its weight of KOH and 3 times its weight of KNO_3 in a gold crucible, the cold mass is treated with cold water, in which K iridate remains insoluble. The insoluble is well washed with water containing a little KOH and NaClO , and then with water, fairly conc cold NaClOAq is added to the residual blue solid, after a time the water is distilled off, the residue is again fused with KNO_3 and KOH, and treatment with dilute NaClOAq and KOHAq is repeated. The blue solid is now dissolved in *aqua regia*, the liquid is evaporated to dryness, and the residue is redissolved and filtered, the dark-coloured liquid is slowly poured into conc NaOHAq containing NaClO , and Cl_2 is passed in, the liquid being kept in a distilling apparatus, the blue oxide of Ir thus obtained is collected, washed, dried, and reduced in a mixture of CO and CO_2 (made by gently warming oxalic acid with sulphuric acid). Metallic Ir is thus obtained, while any Fe present remains as oxide. The mass is heated to redness with KHSO_4 , and repeatedly washed with ClAq to remove Au, and with HFAq to remove SiO_2 , it is finally washed with water and dried. Pt may be removed by dissolving in *aqua regia*, saturating with NH_3Cl , dissolving the double NH_3 , Ir and NH_3 , Pt chlorides in hot water, reducing by SO_2 , when $\text{IrCl}_3 \cdot 3\text{NH}_3\text{Cl}$ is formed, and dissolves with olive green colour, while $\text{PtCl}_2 \cdot 2\text{NH}_3\text{Cl}$ remains insoluble, the reduction should be stopped before the whole of the $\text{IrCl}_3 \cdot 2\text{NH}_3\text{Cl}$ is reduced (the presence of a little of this salt gives a deep red colour to the mixed chlorides). The solution is oxidised by HNO_3 , NH_3Cl is added, and the ppd $\text{IrCl}_3 \cdot 2\text{NH}_3\text{Cl}$ is washed with NH_3ClAq , and strongly heated, when Ir remains as a grey metallic powder (Claus, *J pr* 42, 251). Wöhler a Mucklé (*A* 104, 368) reduce the mixed Pt NH_3 and Ir NH_3 chlorides by digesting with slightly warm KCNaq till the undissolved is light yellow brown, taking care to avoid excess, $\text{IrCl}_3 \cdot 3\text{NH}_3\text{Cl}$ is formed and

dissolves, while $\text{PtCl}_2 \cdot 2\text{NH}_4\text{Cl}$ remains unreduced and insoluble. For other methods of preparing Ir v Deville a Debray (*A Ch* [8] 56, 481), Claus (*C C* 1862 129), Wöhler (*P* 81, 161, 104, 363; 107, 857), Fremy (*A Ch* [8] 44, 885), Martius (*A* 107, 360), Bunsen (*A* 146, 274).

Properties -- As prepared by heating $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$, Ir forms a grey spongy mass, Ir as a grey powder is produced by heating $\text{IrCl}_3 \cdot 2\text{KCl}$ with excess of Na_2CO_3 , washing and reducing in H, by heating to whiteness and compressing, a compact lustrous mass is obtained. When fused in a very powerful O H flame, Ir forms a white, lustrous mass resembling polished steel, brittle when cold, somewhat malleable at red heat (D a D). Harder than iron. SG of porous Ir varies from 16 to 19. Ir which has been very strongly heated is insoluble in all acids, Ir black is sol in *aqua regia*. Heated in Cl, Ir black forms IrCl_3 .

The atomic wt of Ir has been determined by heating $\text{IrCl}_3 \cdot 2\text{HCl}$ in H (Berzelius, *P* 13, 435, 527, 15, 208), by reducing $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ in H and weighing the residual Ir, and by reducing the double Ir-K chloride in H and dissolving out the KCl (Seubert, *B* 11, 1767). As no compound of Ir has been gasified, the valency of the atom of Ir in gaseous molecules is not determined. From the crystalline form of osmium G Rose (*P* 77, 143) concluded that Os and Ir are isomorphous, and that both belong to the hexagonal system.

In its chemical reactions, Ir is closely related to Os and Pt, and less closely but very distinctly related to Ru, Rh, and Pd, all these elements are metallic, but the instability of their salts, the solubility of the hydrated oxides MO_2 in alkalis, and the formation of acids H_2MCl_4 and H_2MBr_4 , show the non-metallic tendencies of the Pt metals (v. NOBLE METALS).

Ir is used alloyed with Pt for making instruments, &c., which remain unchanged in air, & q for making the normal metre preserved as the standard of reference. Stylographic pens are sometimes tipped with Ir. When Ir powder is heated to whiteness with $\frac{1}{4}$ its weight of P the whole melts, on cooling, the mass may be readily worked, by strongly heating with lime, the P is entirely removed.

Reactions and Combinations -- 1 Heated in oxygen, compact Ir is not oxidised, Ir black is oxidised to Ir_2O_3 , which decomposes again at c 1000° (Deville a Debray, *C R* 1878 441, cf. Dissociation, vol II p 397). -- 2 Ir black is oxidised by fusion with *nitre*, *potash*, *potassium carbonate*, or *potassium hydrogen sulphate*. -- 3 Heated in *chlorine* IrCl_3 is formed, mixed with NaCl or KCl, and heated in Cl, soluble $\text{IrCl}_3 \cdot 2\text{Na}(\text{K})\text{Cl}$ is formed. -- 4 Heated in an *alcohol flame*, Ir becomes covered with a blackish layer which disappears on heating in air, leaving a portion of the Ir combined with C (t. IRIDIUM CARBID). -- 5 Ir probably combines with *phosphorus* when the elements are heated together, when the product is heated in air, Ir and a phosphate of Ir are formed.

Iridium alloys of Faraday a Stodart (*A Ch* 21, 73), Deville a Debray (*C R* 81, 839), Fixeau (*C R* 78, 1205), Morin (*C R* 78, 1502), Wöhler (*A* 146, 875).

Osmium-iridium alloy Occurs in South

America, California, Australia, Ural Mountains, &c. Hexagonal prisms, lustrous, steel grey. Slightly malleable, SG 19.3 to 21.1. Analyses show composition approximating to formulae Ir_2Os , IrOs and IrOs_2 , with Ir more or less replaced by Pt, Rh, and Ru, but it is probably non-homogeneous (D a D). Heated in air, OsCl_4 is given off, heated with KNO_3 and KOH K osmate and iridate are formed. Scarcely acted on by *aqua regia*. Alloys with Fe (F).

Platinum-iridium alloy Occurs native in octahedra. 1 pt Ir heated in O H flame with 10 pts Pt gives a ductile alloy, Pt alloyed with 15-20 p.c. Ir is insoluble in *aqua regia*. For accounts of the Pt-Ir alloy used for making the normal standard metre v. D a D and also M. Alloys of Ir with Pt and Rh, and with Pt, Rh, and Sn were prepared by D a D. Alloys of Ir with Cu, Au, Pb, Hg, Ru, and Sn have been prepared.

Iridium, ammonio salts of, or Irid ammonium salts (Ammoniacal iridium bases) IrCl_3 dissolves in $(\text{NH}_4)_2\text{CO}_3$ aq and on neutralising with HCl aq, the compound $\text{IrCl}_3 \cdot 2\text{NH}_3$ is produced, treated with H_2SO_4 aq, this compound yields $\text{IrSO}_4 \cdot 2\text{NH}_3$. $\text{IrCl}_3 \cdot 2\text{NH}_3$ dissolves in boiling NH_4Aq , and the compound $\text{IrCl}_3 \cdot 4\text{NH}_3$ forms on cooling, this compound gives a sulphate and nitrate, SO_4 and 2NO_3 replacing Cl_2 . From $\text{IrCl}_3 \cdot 3\text{NH}_3$ Cl is obtained $\text{IrCl}_3 \cdot 5\text{NH}_3$, and this again yields a basic hydroxide $\text{Ir}(\text{OH})_3 \cdot 5\text{NH}_3$, a carbonate $\text{Ir}_2(\text{CO}_3)_3 \cdot 10\text{NH}_3$, and other salts. Finally by treating $\text{IrCl}_3 \cdot 2\text{NH}_3$ with conc. HNO_3 aq the compound $\text{IrCl}_3 \cdot (\text{NO}_3)_2 \cdot 4\text{NH}_3$ is obtained, AgNO_3 aq does not ppt Cl from this salt, treated with HCl aq the salt $\text{IrCl}_3 \cdot \text{Cl}_2 \cdot 4\text{NH}_3$ is produced from which AgNO_3 aq ppts only half the Cl. The foregoing compounds may be formulated as double salts of IrCl_3 , IrCl_4 , IrCl_5 , &c., with NH_3 , but many of their reactions are better explained if we regard them as salts of condensed ammoniums containing Ir. The following classification is that usually adopted --

1 IRIDOSAMMONIUM COMPOUNDS $\text{N}_2\text{H}_5\text{IrX}_2$, and $\text{N}_2\text{H}_5\text{IrX}_2$, or $\text{NH}(\text{NH}_4)\text{IrX}_2$, and $\text{N}_2\text{H}_5(\text{NH}_4)_2\text{IrX}_3$, &c., obtained from IrCl_3 .

Iridosammonium chloride $\text{N}_2\text{H}_5\text{IrCl}$ (simplest formula $\text{IrCl}_3 \cdot 2\text{NH}_3 = \text{di-ammonio-iridium dichloride}$) A yellow, curdy pp, obtained by dissolving IrCl_3 in excess of $(\text{NH}_4)_2\text{CO}_3$ aq and neutralising the greenish yellow liquid with HCl aq. Insol hot and cold water. Heated gives NH_4Cl , HCl and Ir (Skoblikoff, *A* 84, 275). Heated with H_2SO_4 aq, easily soluble orange coloured **iridosammonium sulphate**, $\text{N}_2\text{H}_5\text{IrSO}_4$, is produced.

Iridoso diammonium chloride $\text{N}_2\text{H}_5\text{Ir}_2\text{Cl}_3$ or $\text{N}_2\text{H}_5(\text{NH}_4)_2\text{Ir}_2\text{Cl}_3$ (simplest formula $\text{IrCl}_3 \cdot 4\text{NH}_3 = \text{tetrammonio-iridium dichloride}$) $\text{IrCl}_3 \cdot 2\text{NH}_3$ is boiled with NH_4Aq until almost all dissolved, the solution is filtered and allowed to cool. Nearly white pp, insol in cold water, heated, or placed in boiling water, goes to $\text{IrCl}_3 \cdot 2\text{NH}_3$ (Skoblikoff, *l.c.*) The **sulphate**, $\text{N}_2\text{H}_5\text{Ir}_2\text{SO}_4$, is obtained by the action of H_2SO_4 aq on the chloride, and the nitrate, $\text{N}_2\text{H}_5\text{Ir}_2(\text{NO}_3)_4$, by addition of Ba_2NO_3 aq to a solution of the sulphate in warm water.

2 IRIDAMMONIUM COMPOUNDS $\text{N}_2\text{H}_5\text{Ir}_2\text{X}_4$, or $\text{N}_2\text{H}_5(\text{NH}_4)_2\text{Ir}_2\text{X}_4$, obtained from IrCl_3 .

Irido pentammonium chloride $\text{N}_2\text{H}_5\text{Ir}_3\text{Cl}_4$ (simplest formula $\text{IrCl}_3 \cdot 10\text{NH}_3 = \text{decammonio-}$

iridium trichloride $\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}$ is dissolved in water, an equal volume of conc. NH_4Aq is added, a flask is quite filled with the liquid, and allowed to stand for several weeks in a warm place until the olive green colour of the liquid has changed to deep rose red, after gentle warming, to remove excess of NH_3 , the liquid is saturated with HClAq and evaporated to dryness, the greenish yellow salt which separates during evaporation is washed with cold water, and then crystallised from water acidified with HCl . Flesh-coloured, crystalline, powder, v. sol water (Claus, *J pr* 63, 99, A 98, 317).

Irido pentammonium hydroxide

$\text{N}_5\text{H}_4\text{Ir}_2(\text{OH})_2$. Known only in solution which is obtained by digesting the chloride with moist Ag_2O . Solution is alkaline, neutralised by acids gives carbonate, nitrate, and sulphate.

3 IRIDI AMMONIUM COMPOUNDS $\text{N}_5\text{H}_4\text{IrCl}_2 \text{X}$, or $\text{N}_5\text{H}_4(\text{NH}_4)_2\text{Cl}_2\text{IrX}$, obtained from series 1 by oxidation.

Iridi-diammonium chloride? better *chloriridi-diammonium chloride* $\text{N}_5\text{H}_4\text{IrCl}_2\text{Cl}_2$ (simplest formula $\text{IrCl}_4 \cdot 4\text{NH}_3 = \text{tetrammonioiridium tetrachloride}$). Obtained by slowly warming iridosammonium chloride ($\text{N}_5\text{H}_4\text{IrCl}_2$) with conc. HNO_3Aq , dissolving the salt which separates in hot water, adding excess of HClAq , and crystallising from hot water. Violet octahedra, AgNO_3Aq ppts only $\frac{1}{2}$ the Cl from this salt. The salt which separates after treating $\text{N}_5\text{H}_4\text{IrCl}_2$ with HNO_3 is the *nitrate*, $\text{N}_5\text{H}_4\text{IrCl}_2(\text{NO}_3)_2$, AgNO_3Aq does not ppt Cl from this salt. When this salt is evaporated with dilute $\text{H}_2\text{SO}_4\text{Aq}$, the *sulphate*, $\text{N}_5\text{H}_4\text{IrCl}_2\text{SO}_4$, is obtained (Skoblikoff, *lc*). Palmaer (*B* 22, 15) describes $\text{N}_5\text{H}_4\text{IrCl}_2\text{Cl}_2$, $\text{N}_5\text{H}_4\text{IrCl}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$, $\text{N}_5\text{H}_4\text{IrCl}_2(\text{NO}_3)_2$, $\text{N}_5\text{H}_4\text{IrCl}_2\text{Cl}$, and $(\text{N}_5\text{H}_4\text{IrCl}_2)_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$.

References — For other memoirs besides those referred to, v. Weltzien, A 97, 19, Gibbs a Genth, *J* 1858 214, Birnbaum, *B* 12, 1544.

Iridium boride of. When Ir is heated with B to a very high temperature a fusible mass is obtained, no definite boride has been isolated (Wöhler a Deville, *A Ch* [3] 52, 71).

Iridium bromides of (Birnbaum, A 133, 161). Only one bromide has been isolated, $\text{IrBr} \cdot 4\text{H}_2\text{O}$, there are indications of the existence in solution of a tetrabromide, IrBr_4 . Ir does not combine directly with Br, nor is it soluble in a mixture of HNO_3 and HBrAq .

IRIDIUM TRIBROMIDE $\text{IrBr}_3 \cdot 4\text{H}_2\text{O}$ (*Iridobromide* *iridium sesquibromide*). When the blue hydrate IrO_2H_2 (obtained by heating a solution of IrCl_3 with alkali) is dissolved in HBrAq and evaporated *in vacuo*, olive green six-sided crystals separate, and then steel blue needles. The olive-green crystals are $\text{IrBr}_3 \cdot 4\text{H}_2\text{O}$, and the steel-blue crystals are $\text{IrBr}_3 \cdot 3\text{HBr} \cdot 3\text{H}_2\text{O}$. The bromide loses $3\text{H}_2\text{O}$ at 100° – 120° , it is sol water, insol alcohol or ether, aqueous solution is green, but becomes blue probably with formation of IrBr .

Irido-bromhydric acid

$\text{IrBr}_3 \cdot 3\text{HBr} \cdot 3\text{H}_2\text{O} (= \text{H}_3\text{IrBr}_3 \cdot 3\text{H}_2\text{O})$. Crystallises in steel-blue crystals which melt at 100° , giving off $8\text{H}_2\text{O}$, deliquescent, easily sol water, alcohol, ether, oxidised by HNO_3 , probably to IrBr_4 .

Ammonium-iridium tribromide, or *Ammonium iridobromide* or *bromiride*

$2(\text{IrBr}_3 \cdot 3\text{NH}_4\text{Br}) \cdot 3\text{H}_2\text{O}$, is obtained by reducing $\text{IrBr}_3 \cdot 2\text{NH}_4\text{Br}$ (formed by adding $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ to hot NaBrAq and cooling) by SO_2 and neutralising by $(\text{NH}_4)_2\text{CO}_3$. The following other double salts are described by Birnbaum (A 133, 161): $\text{IrBr}_3 \cdot 3\text{H}_2\text{GBr}$, $\text{IrBr}_3 \cdot 3\text{AgBr}$, $\text{IrBr}_3 \cdot 3\text{KBr} \cdot 3\text{H}_2\text{O}$, $\text{IrBr}_3 \cdot 3\text{NaBr} \cdot 12\text{H}_2\text{O}$.

IRIDIUM TETRABROMIDE (*Iridibromide*). When IrO_2H_2 is dissolved in HBrAq , or when $\text{IrBr}_3 \cdot 2\text{KBr}$ is decomposed by $\text{H}_2\text{SiF}_6\text{Aq}$, a solution is obtained which loses Br on evaporation, and on addition of HNO_3Aq , after evaporation, gives a deliquescent, blue, crystalline mass, easily sol in water and alcohol. The blue solution probably contains $\text{IrBr}_3 \cdot 2\text{HBr}$ (Birnbaum). This solution does not yield double compounds with other metallic bromides.

Ammonium iridium tetrabromide, or *Ammonium iridibromide* or *bromiride* $\text{IrBr}_3 \cdot 3\text{NH}_4\text{Br}$ ($(\text{NH}_4)_3\text{IrBr}_4$). Dark blue octahedra, by adding $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ to hot NaBrAq , and cooling.

Potassium bromiride $\text{IrBr}_3 \cdot 2\text{KBr}$ (K_2IrBr_5). When solution of IrCl_3 , or $\text{IrCl}_3 \cdot 2\text{NaCl}$, or $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ is warmed with conc. KBrAq , a greenish blue liquid is obtained from which very dark blue crystals of K_2IrBr_5 separate, the salt is recrystallised from hot water.

Sodium bromiride also exists

Iridium carbide of (? IrC). When a coherent mass of Ir is held in the flame of a spirit lamp, black masses appear on the surface, these burn when heated in air and leave 80.2 pct Ir (Berzelius, *P* 15, 213).

Iridium chlorides of. Three chlorides are known IrCl_3 , IrCl_4 , and IrCl_5 , as none has been gashed the formulae are not necessarily molecular (v. *Iridium, haloid compounds* of). When Ir black is heated in Cl_2 , IrCl_3 is formed, when Cl_2 is passed over a heated mixture of Ir black and KCl , $\text{IrCl}_3 \cdot 2\text{KCl}$ is produced.

IRIDIUM DICHLORIDE (*Iridosochloride*) IrCl_2 . A blackish green, insoluble, solid. By passing Cl over Ir black heated to low redness (Berzelius, *P* 13, 470). The change is not complete, as the temperatures of formation and decomposition are nearly the same (Claus, A 59, 219). By heating Ir sulphite in Cl_2 (Fellenberg, *P* 50, 66). By carefully heating IrCl_3 (Skoblikoff, A 84, 275). Seubert (*B* 11, 1761) describes an acid $\text{IrCl}_3 \cdot \text{H}_2\text{SO}_4 \cdot 4\text{NH}_4\text{Cl}$ from which salts of NH_4 and Na are obtained.

IRIDIUM TRICHLORIDE (*Iridochloride* *iridium sesquichloride*) IrCl_3 . Olive green solid, insol in acids or alkalis (Claus, A 107, 129). Obtained by heating Ir black in Cl_2 , also by strongly heating an alkali double salt of IrCl_3 with conc. H_2SO_4 , and pouring into cold water (Berzelius, *P* 13, 470). A soluble hydrate $\text{IrCl}_3 \cdot 4\text{H}_2\text{O}$ is obtained by dissolving IrO_2H_2 in HClAq , reducing by H_2S , and evaporating.

Double salts *Ammonium iridium trichloride* (*Ammonium chloriride*) $2(\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}) \cdot 3\text{H}_2\text{O}$, formed by slowly evaporating mixed solutions of $\text{IrCl}_3 \cdot 3\text{NaCl}$ and NH_4Cl , or by reducing $\text{IrCl}_3 \cdot 2\text{NH}_4\text{ClAq}$ by H_2S , adding conc. NH_4ClAq , filtering if necessary, and slowly evaporating (Claus, *J pr* 42, 851; Seubert, *B* 11, 1761), olive green, rhombic plates.

Potassium chloriridate $\text{IrCl}_3 \cdot 3\text{H}_2\text{O}$ By reducing $\text{IrCl}_3 \cdot 2\text{KCl}$ in H_2S , and evaporating with addition of KCl . Olive-green efflorescent prisms. The following double salts are also known — $2\text{IrCl}_3 \cdot (12\text{NH}_3, \text{Co})\text{Cl}_6$, $\text{IrCl}_3 \cdot 3\text{H}_2\text{O}$, $\text{IrCl}_3 \cdot 3\text{AgCl}$, $\text{IrCl}_3 \cdot 3\text{NaCl} \cdot 12\text{H}_2\text{O}$ (Claus, *l. c.*, Karmrodts a Uhrlaub, *A* 81, 120)

IRIDIUM TETRACHLORIDE (Iridochloride) IrCl_4 . The solution obtained by decomposing $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ suspended in water by Cl contains IrCl_4 (Vauquelin, *A Ch* 89, 150, 225), a solution of IrCl_4 is also obtained by dissolving $\text{IrO}_2 \cdot \text{H}_2\text{O}$ in HCl aq, digesting $\text{IrCl}_3 \cdot \text{aq}$ with *aqua regia*, or decomposing $\text{IrCl}_3 \cdot 2\text{KCl}$ with $\text{H}_2\text{SiF}_6 \cdot \text{aq}$ (Berzelius, *P* 13, 470). By evaporating these solutions to dryness at temperatures not above 40° , IrCl_4 is obtained as a black mass, translucent with dark-red colour at the edges, very deliquescent, decomposed by heat to IrCl_3 and Cl_2 , and then Ir combines with alkali chlorides to form double salts **Ammonium iridium tetrachloride (Ammonium chloriridate)** $\text{IrCl}_4 \cdot 2\text{NH}_4\text{Cl}$, obtained by mixing conc solutions of NH_4Cl and IrCl_3 , or $\text{IrCl}_3 \cdot 2\text{NaCl}$. Crystallises from hot water in dark red brown octahedra, isomorphous with $\text{PtCl}_4 \cdot 2\text{NH}_4\text{Cl}$. Soluble in cold water. Reduced by SO_2 to the more soluble $\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}$.

Potassium chloriridate $\text{IrCl}_3 \cdot 2\text{KCl}$ Formed by mixing conc solutions of its constituent salts, also by dissolving $\text{IrO}_2 \cdot \text{H}_2\text{O}$ in HCl aq (solution probably contains H_2IrCl_6) and adding KCl , also by passing Cl_2 at a gentle heat over an intimate mixture of Ir black and KCl , dissolving in hot water, filtering from Ir , evaporating to dryness with addition of *aqua regia*, dissolving out KCl by small quantities of cold water, dissolving in hot water, adding a little *aqua regia*, and evaporating to the crystallising point. Black octahedra, very soluble in cold water, much more soluble in hot water, insoluble in alcohol. Heated, goes to $\text{IrCl}_3 \cdot 3\text{KCl}$ and at higher temperature to Ir and KCl .

The following **chloriridates** have also been obtained — $\text{IrCl}_3 \cdot 2(\text{NH}_4, \text{CH}_3)\text{Cl}$ (Vincent, *C R* 100, 112), $\text{IrCl}_3 \cdot 2\text{NaCl} \cdot 6\text{H}_2\text{O}$ (Vauquelin, *l. c.*, Berzelius, *l. c.*)

Iridium cyanides of, also **Iridicyanides**, *v* vol II p 332

Iridium haloid compounds of The only haloid compound certainly formed by direct union of the elements is IrCl_3 . When an intimate mixture of Ir black and KCl is heated in Cl_2 , or of Ir black and KI is heated in I_2 , the double salt K_2IrCl_6 or K_2IrI_6 is obtained. The following formulæ present the composition of the haloid compounds and the double salts which they form with alkali haloid compounds —

double alkali-iridium haloid salts are probably better regarded as salts of the acids H_2IrX_6 , H_2IrX_4 , and H_2IrX_2 . The chloriridates (salts of H_2IrCl_6) are readily reduced to chloriridites (salts of H_2IrCl_4).

Iridium hydroxides of, *v* **Iridium oxides** and **hydrated oxides** of

Iridium iodides of (Oppler, *Ueber Iodverbindungen des Iridiums* (Göttingen, 1857), *J* 1857 263) Two iodides, IrI_3 and IrI_2 , have been isolated. There are indications of the existence of IrI_2 . Ir and I do not directly combine.

IRIDIUM DI IODIDE (Iridoso iodide) The brown solid obtained by leading SO_2 into IrI_3 suspended in water is perhaps IrI_2 . When a solution of $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ in boiling KIAq is allowed to cool, a black crystalline powder separates, this is **ammonium iridium di iodide**, $\text{IrI}_2 \cdot 2\text{NH}_4\text{I}$.

IRIDIUM TRI IODIDE (Irido iodide Iridium sesqui iodide) IrI_3 . A black crystalline pp., by adding NH_4Cl to $\text{IrI}_3 \cdot 2\text{KIAq}$. Very slightly soluble in cold water, more soluble in hot water.

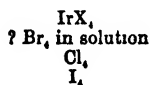

Double salts — Ammonium iridium tri iodide (Ammonium iodiridate) $2(\text{IrI}_3 \cdot 3\text{NH}_4\text{I}) \cdot \text{H}_2\text{O}$. Crystalline needles, by dissolving $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ in boiling KIAq , cooling, filtering from $\text{IrI}_2 \cdot 2\text{NH}_4\text{I}$, concentrating, and recrystallising from hot water.

Potassium iodiridate, $\text{IrI}_3 \cdot 3\text{KI}$. Green lustrous crystalline powder, by reducing IrCl_3 by H_2S with addition of KIAq . **Silver iodiridate**, $\text{AgI} \cdot 3\text{KI}$, has also been obtained.

IRIDIUM TETRA IODIDE (Iridi iodide) IrCl_4 . A black powder, by boiling $\text{IrCl}_3 \cdot \text{aq}$ with KI in presence of a little HCl .

Double salts — Ammonium iridium tetra iodide (Ammonium iodiridate) $\text{IrI}_4 \cdot 2\text{NH}_4\text{I}$. Separates after some weeks from solution of $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ in cold conc KIAq , dark brown lustrous crystals, easily decomposed by heat, aqueous solution gently heated deposits IrI_3 and $\text{IrI}_2 \cdot 2\text{NH}_4\text{I}$. **Potassium iodiridate**, K_2IrI_6 . Separates, after IrI_3 , from solution of IrCl_3 in KIAq . Also formed by dissolving IrI_3 in KIAq , and allowing to crystallise, also, in small quantity, by action of I vapour on an intimate mixture of Ir black and KI at 60° – 70° . **Sodium iodiridate**, $\text{IrI}_4 \cdot 2\text{NaI}$, has also been obtained.

Iridium oxides and hydrated oxides of The only oxides of Ir which have been certainly isolated are Ir_2O_3 and IrO . The former forms a hydrate with $3\text{H}_2\text{O}$, and another hydrate probably with $5\text{H}_2\text{O}$. IrO forms the hydrate $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$. Hydrated Ir_2O_3 dissolves in alkalis probably with formation of **iridates**, $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$.

Double salts.

None of the Ir haloid compounds has been gasified. The formulæ are given from the analogies between these compounds and those of other Pt metals. The only binary compounds of Pt metals which have been gasified are OsO_4 and RuO_4 . The acid H_2IrBr_6 has been obtained. The

Vol. III

dissolves in some acids, but no salts have thus been prepared. **Alkaline iridates** appear to exist. There are indications of the existence of an oxide with less O than Ir_2O_3 , probably IrO . When Ir black is heated in O , Ir_2O_3 is formed, the oxide decomposes again at c 1000° . IrO_2 is the most

E

stable oxide, $\text{Ir}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ rapidly absorbs O from the air, and passes into $\text{IrO}_2 \cdot x\text{H}_2\text{O}$.

IRIDIOUS OXIDE (*Iridium monoxide*) IrO When IrCl_3 is boiled with KOH aq a black powder separates, this is probably IrO (Berzelius, P 13, 479) Claus (A 59, 249) thinks that this oxide is obtained by heating one of the double salts of IrSO with K_2CO_3 in a stream of CO_2 . On adding KCl aq to $\text{IrCl}_3 \cdot 3\text{NaCl}$ aq, and filtering, a solution of IrCl_2 is obtained, when K_2CO_3 aq is added to this liquid (or to $\text{IrCl}_3 \cdot 3\text{KCl}$ aq) a greyish green pp is formed, which is probably a hydrate of IrO , the pp is sol in excess of K_2CO_3 aq (Berzelius, *lc*). A few salts derived from IrO are known, e.g. $\text{IrSO}_2 \cdot 4\text{H}_2\text{O}$, they are not, however, formed directly from the oxide, but by reducing $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$ or chloriridates by SO_2 .

IRIDIC OXIDE AND HYDRATE (*Iridium dioxide*) IrO_2 and $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$ By adding excess of alkali to IrCl_3 aq and heating, a heavy indigo blue pp $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$ is produced. The same compound is obtained by using IrCl_3 aq in place of IrCl_3 , and allowing the pp to stand in the air, when it absorbs O. The pp is soluble in HCl aq with formation of IrCl_4 , it is insoluble in dilute H_2SO_4 aq or HNO_3 aq. When the hydrate is heated in a stream of CO_2 , IrO_2 remains as a black powder quite insoluble in acids (Claus, A 59, 249). No salts corresponding with IrO_2 have been prepared. By adding CaO aq to a solution of $\text{IrO}_2 \cdot \text{H}_2\text{O}$ in HCl aq a blue pp is obtained, which is a compound of IrO_2 with CaO . When Ir black is fused for some time with KNO_3 , and the blackish-green mass is treated with water, part dissolves, forming a deep indigo blue solution, and part remains as a black crystalline powder. The quantity of K in this powder is variable, but the ratio of IrO is always 1.3 (Claus, A 59, 249). The powder is probably an iridate of K, $\text{IrO}_2 \cdot x\text{K}_2\text{O}$.

IRIDO-IRIDIC OXIDE AND HYDRATES (*Iridium sesquioxide*) Ir_2O_3 and $\text{Ir}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ The oxide Ir_2O_3 is obtained by heating $\text{IrCl}_3 \cdot 2\text{KCl}$ with 2 parts K_2CO_3 , or Na_2CO_3 , in a stream of CO_2 , washing the fused mass with boiling water, and then with water containing NH_4Cl , heating to remove NH_4Cl , treating with acid to remove alkali, and again washing with water (Claus, A 59, 249). A hard blue black powder, decomposed by heating to c. 1000° into Ir and O (Deville & Debray, C R 1878 441, cf. Dissociation, vol. II p 397). Reduced to Ir by H at the ordinary temperature. The hydrate $\text{Ir}_2\text{O}_3 \cdot 8\text{H}_2\text{O}$ ($= \text{Ir}_2\text{O}_3 \cdot \text{H}_2\text{O}$) is obtained by adding to $\text{IrCl}_3 \cdot 2\text{NaCl}$ aq so much KOH aq that all remains dissolved, and then heating or ppg by alcohol. Black pp insol in acids except conc HCl aq, which dissolves it very slightly. By adding a little KOH aq to solution of an alkaline chloriridate, and quite filling a flask with the liquid, a yellow green pp forms, which is probably $\text{Ir}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$, it oxidises very easily to the blue $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$, easily soluble in the slightest excess of alkali. De Boisbaudran (C R 96, 1236, 1406, 1551) describes a violet coloured pp, which is probably $\text{Ir}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, obtained by adding alkali to $\text{Ir}_2(\text{SO}_4)_3 \cdot 3\text{K}_2\text{SO}_4$ aq (this salt is formed by heating Ir compounds with KHSO_4 , and treating the product with K_2SO_4 aq). A few salts, and some double and basic salts, corresponding with Ir_2O_3 are known, they are pro-

duced indirectly. The sulphites and double sulphites are produced by reducing $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$ or chloriridates by SO_2 . By adding CaO aq to IrCl_3 aq a yellow pp of $\text{Ir}_2\text{O}_3 \cdot 8\text{CaO}$ is produced (Claus, A 59, 249). Compounds of Ir_2O_3 with NO_2 and with nitrites are described by Gibbs (B 4, 280).

IRIDIUM, oxychloride of An oxychloride of Ir is said by Berzelius (P 13, 484) to be formed as a yellowish-brown pp by adding a small quantity of HgNO_3 aq to $\text{IrCl}_3 \cdot 2\text{KCl}$ aq, HgCl_2 goes into solution, addition of more HgNO_3 causes ppg of HgCl .

IRIDIUM, phosphide of. When Ir is very strongly heated with $\frac{1}{2}$ its weight of P, the whole melts. By heating the product with CaO the P is removed. Ir and P probably combine when heated together, but no phosphide of Ir has been isolated.

IRIDIUM, salts of Very few salts of Ir are known other than the haloid compounds. Iridous sulphite, $\text{IrSO}_2 \cdot 4\text{H}_2\text{O}$, and some double sulphites, irido-iridic sulphite, $\text{Ir}_2(\text{SO}_4)_3 \cdot 6\text{H}_2\text{O}$, and several double and basic sulphites, and a few other salts (chiefly double and basic), corresponding with Ir_2O_3 , have been isolated. None of these salts is obtained from the corresponding oxide, the sulphites, which are the best known salts, are formed by reducing $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$ or chloriridates, by SO_2 aq.

IRIDIUM, sulphides of Three sulphides of Ir are known, IrS , Ir_2S_3 , and IrS_2 . Ir combines with S when heated with it.

IRIDOUS SULPHIDE IrS (*Iridium monosulphide*) A blue black solid, by heating IrS_2 or IrS_3 (Berzelius, P 13, 487, Böttger, J pr 3, 227). The pp obtained by passing H_2S into a solution of an iridous compound is probably IrS . Does not decompose by heating in absence of air, roasted in air gives SO_2 and a basic sulphate. The ppd sulphide dissolves in KHSAq .

IRIDIC SULPHIDE IrS_2 (*Iridium disulphide*) A black powder, obtained by strongly heating Ir black with S and Na_2CO_3 , and washing with water (Fellenberg, P 50, 66). Heated in air gives SO_2 and Ir . Berzelius (*lc*) obtained a dark brownish-yellow pp by passing H_2S into IrCl_3 aq, heated, this gave IrS .

IRIDO-IRIDIC SULPHIDE Ir_2S_3 (*Iridium sesquisulphide*) A brown black pp by passing H_2S into solution of an irido-iridic compound. Heated gives SO_2 and S, and leaves IrS (Berzelius, *lc*).
M M P M

IRIDOLINE $\text{C}_{10}\text{H}_8\text{N}$ ($252^\circ - 257^\circ$ S G 15 1072). A base occurring in coal tar oil (G Williams, Tr E 21, 377, C J 16, 375).

IRIDOSMIUM v *Iridium*, Alloys of, p 47.

IRIS CAMPHOR $\text{C}_{15}\text{H}_{12}\text{O}_2$. Occurs in the root of *Iris florentina* (Dumas, A 15, 158). Pearly plates, volatile with steam. Insol water. Flückiger (Ar Ph [3] 8, 481), by distilling iris root with steam, obtained crystals of myristic acid saturated with a fragrant oil.

IRISH PEARL MOSS v CARAGHEEN MOSS.

IRISIN $\text{C}_6\text{H}_8\text{O}_4$ aq $[\alpha]_D = -51^\circ$. A carbohydrate extracted from the rhizomes of the water lily (*Iris pseudacorus*) with water and then ppg with lead acetate. Probably identical with graminin (Wallach, A 284, 364, B 21, 396).

Properties — More strongly laevorotatory than inulin — 1. Does not reduce Fehling's solu-

tion Is very easily converted into sugar (chiefly levulose) by weak acids Gives no colouration with iodine V sol strong HI solution from which solution NaOH separates iodoform Also sol HCl, and NaOH Irisin is nearly 4 times as soluble as inulin in water at 22°. Under the microscope the globules of irisin resemble those of inulin, but do not exhibit double refraction

IRON Fe At w 55.9 Mol weight unknown [1550°] (Pouillet), [1587°] (Daniell, Tr 1880), [1600°] (Pictet, P M 1879 446) S G determinations vary from 6.95 (Roberts a Wrightson, A Ch [5] 30, 274) to c 8.2 Almost pure Fe has S G c 7.85 at 16° according to Caron (C R 70, 1263), 8.139 according to Chandler-Roberts (C N 31, 137) S H 111641 at 0°, 112359 at 50°, 113795 at 100° (Byström, *Oefversk Vetensk Förhandl* [Stockholm, 1860] 17, 307, v also Weinhold, P 149, 214) C E 0000.233 at 18° to 100° (Kopp, A 81, 1, v also Fizeau, A Ch [4] 2, 143, C R 68, 1125) T C (Ag=100) 11.9 (Wiedemann a Franz, P 89, 497) E C (Hg at 0°=1) 9.68 at 0°, 6.19 at 100° (Lorenz W 13, 422, 582) Crystallises in regular system (Fuchs, A 84, 257) Emission spectrum is very complex (Angström, P 94, 141, Cornu, *Spectre Normal* [Paris, 1881], Liveing a Dewar, Pr 29, 402, 32, 402) Some of the thermal data for Fe are presented in the following table (Th 3, 293) —

X [Fe, X, Aq]

Cl = 99,950

Br = 78,070

I = 47,650

[Fe, Cl, Aq] = 127,720, [Fe, O, 3H²O] = 191,150,

[Fe²O²H², 3H SO⁴Aq] = 33,840,

[Fe²H²SO⁴Aq] = 24,840

For further details regarding physical properties v Rammelsberg's *Hand der Kryst physikal Chemie*, 1, 193 For the physical properties of different kinds of pig iron, wrought iron, and steel, v DICTIONARY OF APPLIED CHEMISTRY

Occurrence—The metal itself is found in small quantities in rocks of volcanic origin and in lavas, it also occurs in meteorites Compounds of iron are very widely distributed, and occur in immense quantities The spectroscopie shows the existence of iron (or iron compounds) in the sun and other stars The chief ores of iron are *hematite*, FeO, *brown iron ore*, Fe₂O₃·H₂O, *yellow ochre*, Fe₂O₃·2H₂O, *magnetic iron ore*, Fe₃O₄, *spathe ore*, FeCO₃, *pyrites*, FeS₂ (the 'formulae express approximately the compositions of the ores)

Preparation—Commercial iron, whether pig iron, malleable iron, or steel, always contains more or less C and Si, and generally small quantities of P and S, sometimes also traces of Mn, Ti, Ni, Co, Cu, Sb, and As 1 Wöhler (A 94, 126, 95, 192) prepares Fe₂O₃ by heating FeSO₄ crystals with 2-3 parts NaCl in a crucible and washing with water, and reduces the Fe₂O₃ by heating in H (cf G de Claubry, C C 1859 214, Luca, C R 1851 332, 1352, 202). Moissan (C R 89, 176) says the reduction must be carried out at c 700° —2 By reducing FeCl₃ in a stream of H (Peligot, C R 19, 670), or in neutral solution at b point by Zn (Capitaine, C R 9, 757), or by Zn vapour at a high temperature (Poumarède, C R 29, 518) —8 Troost melts

pig iron in a lime crucible by the O-H flame (Bl [2] 9, 250) —4 A mixture of dry Na₂SO₄ and FeSO₄ is heated in a Pt crucible so long as SO₂ comes off, the residue is washed with cold water, and the crystalline Fe₂O₃ is reduced in H in a Pt crucible, and the Fe is melted in the O-H flame (Ma'ithessen a Prus Szczepanowski, C N 20, 501) —5 By electrolysis FeSO₄ saturated with NH₄Cl, Fe appears at the negative pole (a large iron plate), it contains H and other gases, which may be removed by heating (Varrentrap, D P J 187, 152, Lenz, J pr 108, 438)

Properties—A lustrous, greyish white metal Crystallises in regular cubes or octahedra Annealed wrought iron wire is extremely tenacious. Such mechanical treatment as hammering, bending, or torsion changes many of the physical properties of iron The physical properties which have been determined are for the most part those of iron containing small quantities of foreign substances Iron is magnetic (cf Faraday, P 70, 24, Gore, P M [4] 40, 170) Pure, or almost pure, Fe is softer and more malleable, but less tenacious, than ordinary malleable iron The iron obtained by reducing Fe₂O₃ in H at temperatures below c 600° is pyrophoric, the powder obtained at c 700° is non pyrophoric (Moissan, C R 89, 176) By passing a weak electric current through FeSO₄·Aq mixed with MgSO₄, Lenz (C C 1870 188) obtained a greyish, non crystalline, very brittle mass, easily pulverised by the finger, this iron contained c 200 times its volume of gases, chiefly H (v *Iron, hydrides of*), mixed with CO, CO₂, N, and H₂O vapour, by heating *in vacuo* the gases were removed, and the iron then resembled Pt in appearance Iron is unchanged in dry O, but in moist O or in ordinary air it is slowly oxidised to FeO, xH₂O, heated in air or O a mixture of FeO and Fe₂O₃ is produced Iron combines directly with the halogens, also with S, C, B, Si, P, As, it forms alloys with many metals Iron dissolves in the common mineral acids with formation of salts Finely divided Fe decomposes water at 100°

The atomic weight of Fe has been determined (1) by analysing and determining V.D. of FeCl₃ and FeCl₂, (2) by determining S.H. of Fe, (3) by reducing Fe₂O₃ in H (Berzelius, P 8, 165, Svanberg a Norlin, A 50, 432, Erdmann a Marchand, J pr 33, 5, Rivet, A Ch [3] 30, 192), (4) by transforming Fe into Fe₂O₃ (B, A 50, 432, S a N, lc, Maumené, A Ch [3] 30, 380), (5) by determining the Cl in FeCl₃ and in FeCl₂ (Dumas, A Ch [3] 55, 157) The atom of Fe is trivalent in the gaseous molecule FeCl₃, and divalent in the gaseous molecule FeCl₂ (v *Iron, chlorides of*)

Iron is distinctly a metallic element, it replaces the H of most acids, forming two series of salts, the simplest formulae for which are FeX₂ and FeX₃, respectively, X=Cl, NO₃, SO₄, PO₄, &c The ferrous salts, FeX₂, are easily oxidised to ferric salts, FeX₃, very many salts, both normal and basic, of both series have been isolated, numerous double salts are also known. Fe₂O₃ forms compounds with several oxides more basic than itself, e.g. with K₂O, BaO, CaO, MgO, these compounds may be

regarded as *ferrites* derived from the hydroxide $\text{Fe}_2\text{O}_3\cdot\text{H}_2\text{O}$ (= $\text{Fe}_2\text{O}_3\cdot\text{H}_2\text{O}$). There are also some salts known as *ferrates*, e.g. K_2FeO_4 and BaFeO_4 , which may be looked on as derived from the hypothetical *ferric acid* H_2FeO_4 , but neither this acid nor its anhydride, FeO_3 , has been isolated (v *FERRATES and FERRITES*, vol. II pp 546-7). Fe_2S_3 , like Fe_2O_3 , forms some double compounds with more basic sulphides, these double compounds may be regarded as *thioferrites* (v *Iron, sulphides of*). Fe is closely related to Co and Ni, these three metals show some marked analogies with the Pt metals, Fe is also related to Cr and Mn, and it shows some resemblance to Al and the other earth metals (v *IRON GROUP OF ELEMENTS*, also *NOBLE METALS*, and *CHROMIUM GROUP OF ELEMENTS*, and *EARTHS, METALS OF THE*).

Reactions and Combinations—1 Heated in air or oxygen Fe is oxidised to Fe_2O_3 and Fe_3O_4 . 2 Unchanged in dry air at ordinary temperature, but rusts in moist air to $\text{Fe}_2\text{O}_3\cdot x\text{H}_2\text{O}$. 3 Finely divided Fe decomposes water at 100° (v Ramann, B 14, 1433), and rapidly decomposes steam. Compact Fe decomposes steam at red-heat, Fe_2O_3 is produced. Iron slowly rusts in contact with water and ordinary air, the formation of $\text{Fe}_2\text{O}_3\cdot x\text{H}_2\text{O}$ proceeds slowly at first, and then more rapidly, probably because the Fe and Fe_2O_3 exert an electrolytic action on the water, presence of ammoniacal salts increases the rate of rusting, alkalis and alkaline carbonates hinder the rusting. According to Calvert (C N 23, 98) Fe does not rust in water if CO_2 is absent. For an account of the retarding or hastening action of various salts on the rusting of Fe v Wagner, D P J 218, 70. Various processes have been used for preventing iron rusting, covering the iron with Zn is frequently done, Barff & Bower heat the iron to c 650° in water vapour, whereby a hard protecting film of Fe_2O_3 is formed on the surface of the iron. 4 Fe decomposes solution of hydrogen peroxide, forming $\text{Fe}_2\text{O}_3\cdot\text{H}_2\text{O}$, the Fe becomes covered with bubbles of O (Weltzien, A 138, 129). 5 Iron dissolves in dilute sulphuric or hydrochloric acid with evolution of H . Cold conc sulphuric acid is almost without action on Fe, when heated, SO_2 is evolved, and $\text{Fe}_2(\text{SO}_4)_3$ formed. Dilute nitric acid dissolves Fe, forming $\text{Fe}(\text{NO}_3)_2$ and NH_4NO_3 , with evolution of N oxides. Conc nitric acid is almost without action on Fe, v *infra*, Passivity of iron. 6 Heated repeatedly with caustic soda solution Fe forms crystals of $\text{Fe}_2\text{O}_3\cdot\text{H}_2\text{O}$ (Brunck & Graebe, B 13, 725). 7 When Fe is heated to redness in a stream of ammonia a nitride of Fe is formed, Fe_3N_2 , according to Stahl Schmidt (P 125, 37). 8 Fe heated in a closed tube with solution of sulphur dioxide to 200° forms solution of FeSO_4 and crystals of FeS_2 (Geitner, A 129, 350). 9 Fe is oxidised to Fe_2O_3 , or K_2FeO_4 (v vol. II p 547) by fusion with potassium nitrate. 10 Fe combines with the halogens, with arsenic, boron, carbon, hydrogen, nitrogen, phosphorus, and sulphur (v *Iron, chlorides of, borides of, carbides of, &c.*), it also forms alloys with several metals (v *Iron, alloys of*).

Passivity of iron Iron is not acted on by conc nitric acid, iron which has been immersed in conc nitric acid does not dissolve in dilute

nitric acid, nor does it ppt Cu from $\text{CuSO}_4\cdot\text{Aq}$; such Fe is said to be *passive*. Co and Ni, and perhaps Bi, also show passivity. According to Varenne (A Ch [5] 19, 251, 20, 240) immersion of iron in acid of 100 p.c. HNO_3 is not accompanied by evolution of any gas, if the acid has SG 1.882 (c 63 p.c. HNO_3) NO is evolved copiously for 3 to 20 seconds and then ceases, in both cases the Fe becomes passive. Acid of less SG than 1.299 (c 47 p.c. HNO_3) does not produce passivity. If part of a rod of Fe is dipped into conc acid, and then the whole is carefully immersed in a dilute acid, the whole rod is passive. These facts are explained by Varenne by supposing that a gaseous film is deposited on the surface of the iron, and protects the iron from the action of the acid, the gas dissolves in the more dilute acid, in the case of the partly immersed rod the gas bubbles are removed from one part and then adhere to the other part of the rod. This view was also upheld by Mousson (P 39, 330), but was controverted by Faraday and Schönbein (P 39, 342), and Beetz (P 67, 286, 365). Ramann (B 14, 1430) considers the passivity to be due to a layer of Fe_2O_3 , which is soluble in dilute, but insoluble in conc, nitric acid. R thinks that immersion in the acid produces $\text{Fe}(\text{NO}_3)_2$, and that this then reacts with the Fe to produce Fe_2O_3 and NH_4NO_3 , iron wire, according to R, becomes passive when partly heated, also by making it the positive electrode in an O containing liquid. Various oxidising agents acting on Fe render it passive, e.g. HClO_4 , CrO_3 , H_2O_2 (Keir). The passivity of Fe is removed by strongly rubbing the iron, or heating it in reducing gases, also by bringing it into contact with Zn. According to Saint Edme (C R 106, 1079) commercial sheet Ni is passive in ordinary $\text{HNO}_3\cdot\text{Aq}$, Fe in contact with Ni becomes passive in the acid, passive Ni remains passive when heated to bright redness in H , whereas Fe loses its passivity.

Detection and Estimation—Fe compounds are detected by giving a reddish green colour to the hot borax bead in the oxidising flame, which becomes bottle green to nearly colourless when cold, also by the ppn. of brown red $\text{Fe}_2\text{O}_3\cdot x\text{H}_2\text{O}$ by alkalis from ferric compounds, $\text{K}_2\text{FeCy}_4\cdot\text{Aq}$ gives a deep blue pp with ferrous salts, and no pp but a brownish colour with ferric salts. Fe is estimated, gravimetrically, by ppn as $\text{Fe}_2\text{O}_3\cdot x\text{H}_2\text{O}$ and weighing as Fe_2O_3 , volumetrically, by titration with $\text{KMnO}_4\cdot\text{Aq}$ or $\text{K}_2\text{Cr}_2\text{O}_7\cdot\text{Aq}$. For details and for other methods v *ANALYSIS OF ANALYSIS*.

Metallurgy of iron Pure iron is too soft and has too little tenacity for use in making machinery, &c. Ordinary iron is divided into three kinds—pig or cast iron containing from 2 to 5.75 p.c. C, besides small quantities of Si, P, S, and traces of metals other than Fe (chiefly As, Ti, V, Cr, Mn, Cu), malleable or wrought iron containing less than 5 p.c. C, and steel containing about 1 p.c. C. Pig iron is obtained by very strongly heating Fe ores with lime and coal in large furnaces, and blowing in air at the bottom of the furnaces, the C of the coal is burnt chiefly to CO , and this reacting with oxides of Fe produces Fe, which then combines with, or it may be only dissolves, carbon, the C seems to be produced by a reaction between the partly reduced Fe_2O_3

and CO (v Bell, *C J* [2] 7, 203) The reduction of Fe_2O_3 is probably aided by cyanides present in the furnace The greater part of the foreign matter of the iron ores is removed in the form of a fusible slag consisting of silicate of Fe, Ca, Mg, Al, Mn, &c Wrought iron is obtained by *puddling* cast iron, in this process the cast iron is strongly heated along with lumps of Fe_2O_3 in a reverberatory furnace, the Fe_2O_3 is partially deoxidised, and the O is used in burning the C, Si, S, and P, the C being thus almost entirely removed as CO or CO_2 Steel is obtained by completely removing the C from wrought iron by blowing in air, and then adding a sufficient quantity of Fe containing a known quantity of C Steel is also sometimes made by causing wrought iron to take up C by strongly heating the iron with charcoal Cast iron is more fusible, harder, and more brittle than wrought iron, which is more ductile and malleable than cast iron Steel combines the malleability and ductility of wrought iron with the fusibility of cast iron, it is also very hard and elastic Cast iron is divided into two kinds *grey cast iron*, granular, with low malleability, SG c 7.1, melting at c 1600° , this variety contains C partly in combination with Fe and partly uncombined as graphite, *white cast iron*, harder but not so strong as grey, SG c 7.5, melts at a lower temperature than grey, this variety contains only combined C By melting grey, and cooling rapidly, white, cast iron is obtained, by melting white, and cooling slowly, grey, cast iron is produced For details of the metallurgy of iron v DICTIONARY OF APPLIED CHEMISTRY

Iron, alloys of Iron alloys with many metals, the softer metals—Ag, Sn, Zn &c—become harder and more tenacious when alloyed with a few parts of iron per thousand, the alloys may generally be prepared by fusing the various metals with iron wire, a little Fe_2O_3 being added to remove C from the iron

Alloys with *aluminum* have been described, approximately AlFe (Wohler, A 115, 102) approximately AlFe, and AlFe, (Calvert a Johnson, *J* 1855, 326) Sonnenschein (*J pr* 66, 168) described an alloy with *lead* having a composition approximating to Pb_2Fe An *amalgam* of iron is formed by mixing finely divided Fe with Na amalgam, adding a little water, and squeezing out excess of Hg, the crystals correspond in composition to Hg_2Fe_2 , they slowly undergo decomposition, rapidly when much compressed (Raman, *B* 14, 1433) Alloys with the following metals have been described—Sb, Cu (Musket, *P M* [3] 6, 81), Mn (M, *lc*), Mo (Heine, *J pr* 9, 176, Stromeyer, *P* 28, 551, Wiggins, *P* 28, 565, Steinberg, *J pr* 18, 379), Ni, Pd (Faraday a Stodart, *Tr* 1822 254), Pt (Schönbein, *P* 42, 17, Boussingault, *A Ch* [2] 53, 441), K (Calvert, *P M* 1855), Rh (F a S, *lc*), Sn (Lassaigne, *J Chim méd* 6, 609), Ti (Riley, *C J* 16, 387), W (Bernoulli, *P* 21, 573), Zn (Percy, *Metallurgy*, 2, 153)

Iron, arsenides of The minerals *arsenical pyrites* and *mispickel* are compounds of Fe with As and with As and S respectively, their compositions approximate to the formulae FeAs_2 and FeAsS Brittle masses are obtained by fusing together As and Fe out of contact with air, but they have not been much examined

Iron, borides of When Fe is heated in a stream of BCl_3 vapour, a hard, white substance is obtained, which is decomposed by boiling water forming H_2BO_3 (?) and Fe_2O_3 , and evolving H (Fremy, Wurtz's *Dict de chim* 1, 1417) by heating ferric borate in H, Lassaigne (*J Chim mét* 3, 535) obtained a similar compound, no analyses are given

Iron, bromides of Two exist, FeBr_2 and FeBr_3 , both are produced by the direct union of their elements Neither has been gasified, the formulae are given because of the analogies between these salts and FeCl_2 and FeCl_3 (v *Iron, chlorides of*)

FERROUS BROMIDE (*Protobromide of iron*) FeBr_2 A yellow solid, obtained by heating excess of Fe in Br vapour, soluble in water, solution deposits crystals $\text{FeBr}_2 \cdot 6\text{H}_2\text{O}$, decomposed by heating in air to FeBr_3 and Fe_2O_3 (Scheufelen, *A* 231, 156) Thomsen gives $[\text{FeBr}_2, \text{Aq}] = 78,070$ (*Th* 3, 294)

FERRIC BROMIDE (*Sesquibromide of iron*) FeBr_3 Dark red crystals, obtained by heating Fe in excess of Br vapour, may be sublimed, with partial decomposition, out of contact with air, deliquescent Aqueous solution very easily partially reduced by heating to FeBr_2 (L de Koninck, *Zeit anorgan Chem*, 1889 149)

Iron, carbides of Whether pig iron is a carbide of iron, or a mixture of carbides and free C, cannot yet be regarded as finally settled The presence of a few per cents of C in iron very much modifies the properties of the whole, by making it more fusible, if from 2 to 1.5 p c C is present, the mass is only fusible with difficulty, but is very hard and tough, it has the properties of wrought iron or steel, according to the quantity of C Iron takes up C directly, and by so doing has its properties changed On the temperatures at which carburization of Fe occurs with amorphous C, diamond, and graphite, v Hempel, *B* 18, 998

The following carbides of Fe have been described, but the investigation of none of these bodies is complete—(1) Fe_3C , a brittle, fusible mass, by melting together an intimate mixture of equal parts of Fe and C (Faraday a Stodart, *G A* 66, 183), (2) FeC_2 , a black pyrophoric powder, by heating H_2FeCy_3 , or $(\text{NH}_4)_2\text{FeCy}_6$, out of contact with air (Berzelius), or by fusing K_2FeCy_6 , and washing away the KCN produced (Rammelsberg), (3) FeC , was obtained by Karsten by the action of dilute acids on grey pig-iron (*S* 68, 182), (4) FeC , by the action of Br or I on pig iron (Berthier, *J* 1862 127)

Iron, chlorides of Two chlorides of iron, FeCl_2 and FeCl_3 , have been isolated, and a third, Fe_2Cl_4 , perhaps exists When Fe is heated in a stream of Cl, both FeCl_2 and FeCl_3 are produced

FERROUS CHLORIDE FeCl_2 (*Iron dichloride* or *protochloride*) Mol w 126.64 (v *infra*) SG 2.528 (Fulhol, *A Ch* [3] 21, 415), 2.988 at 17.9° (Clarke's *Specific Gravity Tables* [new ed.] 24) VD 62.79 at 1300° – 1400° , 61.55 at 1400° – 1500° (Nilson a Pettersson, *C J* 53, 828) VD at yellow heat 94.4° (V Meyer, *B* 17, 1835), calc for FeCl_2 , 63.32, for Fe_2Cl_4 , 26.64 (v *infra*). HF $[\text{FeCl}_2] = 82,050$, $[\text{Fe}_2\text{Cl}_4, \text{Aq}] = 99,950$; $[\text{FeCl}_2, 4\text{H}_2\text{O}] = 15,150$ (*Th* 3, 293)

Formation.—1. By heating excess of Fe filings

or wire in Cl.—2 By partially reducing FeCl_2 in H (Wöhler, *A* 4, 255)—3 By dissolving Fe in HClAq out of contact with air, evaporating, and drying in a stream of H—4 By heating Fe filings with NH_4Cl out of contact with air

Preparation—Fe wire is heated in a stream of dry HCl, and the product sublimed in the same gas (Wöhler & Liebig, *P* 21, 258)

Properties and Reactions—White, lustrous, six-sided, deliquescent, tablets Heated very strongly in N forms FeCl_2 and Fe (V Meyer, *B* 17, 1335) Heated in O, forms Fe_2O_3 with evolution of Cl Oxidises readily in air to a mixture of FeCl_2 and Fe_2O_3 Heated to redness in steam forms Fe_2O_3 , HCl, and H Heated to redness in a stream of NH_3 , Fe_3N_4 is produced (Fremy, *C R* 52, 321) Heated with PH_3 forms HCl and Fe phosphide A mixture of FeCl_2 and O is reduced by Zn vapour with separation of Fe in crystals (Poumarède, *C R* 29, 520) S c 50 at 80° , less sol in HClAq

Molecular weight of gaseous ferrous chloride By volatilising in HCl at a yellow heat, V Meyer got values for V D which were about the mean between those calculated for FeCl_2 and Fe_2Cl_2 (*B* 17, 1335), calculated for $\text{FeCl}_2 = 63.32$, for $\text{Fe}_2\text{Cl}_2 = 126.64$, observed 92.32 and 96.51 Meyer concluded that molecules of Fe_2Cl_2 probably exist at lower temperatures and molecules of FeCl_2 at a very high temperature Nilson & Pettersson (*C J* 53, 827) obtained values for V D at $c 1400^\circ$ agreeing with that calculated for FeCl_2 , calculated = 63.32, observed at $1300^\circ - 1400^\circ = 62.79$, at $1400^\circ - 1500^\circ = 61.55$ There can be no doubt then that molecules of the composition FeCl_2 exist at $c 1300^\circ - 1500^\circ$

Combinations—1 With water to form the hydrates $\text{FeCl}_2 \cdot 2\text{H}_2\text{O}$ and $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ The former is obtained by saturating warm conc HClAq with FeCl_2 or by passing HCl into saturated FeCl_2Aq , the latter is produced by dissolving Fe in HClAq and concentrating out of contact with air $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ forms blue green, monoclinic, deliquescent, transparent crystals, S G 1.93—2 With nitric oxide, solution of FeCl_2 , especially an alkaline solution, absorbs NO forming a green-brown liquid which contains $\text{FeCl}_2 \cdot \text{NO}$, NO is removed by warming—3 With ammonia to form $\text{FeCl}_2 \cdot 6\text{NH}_3$ and $3\text{FeCl}_2 \cdot 2\text{NH}_3$ (Rogstadius, *J* pr 86, 810) The former is a white powder, produced by passing NH_3 over FeCl_2 at the ordinary temperature, the latter is formed by slowly heating $\text{FeCl}_2 \cdot 6\text{NH}_3$ to melting By strongly heating $3\text{FeCl}_2 \cdot 2\text{NH}_3$ in NH_3 the nitride Fe_3N_4 is formed (Fremy, *C R* 52, 321)—4 With ammonium chloride to form $\text{FeCl}_2 \cdot 2\text{NH}_4\text{Cl}$, obtained by crystallising mixed solutions of FeCl_2 and NH_4Cl , or, according to Hisinger & Berzelius (*G A* 27, 273) (with evolution of NH_3 and H), by boiling Fe filings with NH_4ClAq (cf. Winkler, *R. P.* 59, 171, Vogel, *J* pr 2, 192) A compound $\text{FeCl}_2 \cdot 2\text{KCl} \cdot 2\text{H}_2\text{O}$ is also known (Schabus, *W. A. B* 1850 475) Compounds with CdCl_2 and HgCl_2 , viz $\text{FeCl}_2 \cdot 2\text{CdCl}_2 \cdot 12\text{H}_2\text{O}$ and $\text{FeCl}_2 \cdot \text{HgCl}_2 \cdot 4\text{H}_2\text{O}$ are also described (v Hauer, *W. A. B* 17, 331)

FERRIC CHLORIDE (*Iron sesquichloride* or *perchloride*) FeCl_3 , Mol w 162.01, and probably also 824.03 (v *infra*) ($280^\circ - 285^\circ$) (Friedel & Crafts, *C R* 107, 801) S G 2.804 at 10.8° (Clarke's *Tables of Specific Gravity* [new ed.],

24) V D varies from $c 165$ at 320° to $c 80$ at $1000^\circ - 1800^\circ$ (v *infra*) Crystallises in hexagonal forms $a = 1.1295$, Nordenskiöld (v. Rammelsberg's *Hand der Krystal physikal Chemie*, 1, 260) H F [FeCl_3] = 96.040, [$\text{FeCl}_3 \cdot \text{Cl}$] = 13.990, [$\text{FeCl}_3 \cdot \text{Aq}$] = 127.720, [$\text{FeCl}_3 \cdot \text{Aq} \cdot \text{Cl}$] = 27.770 (*Th* 8, 293)

Occurrence—In the craters of volcanoes

Formation—1 By heating Fe in a stream of Cl—2 By heating FeCl_2 in Cl—3 By strongly heating FeCl_2 in a wide mouthed vessel, Fe_2O_3 remains and FeCl_3 sublimes—4 By passing HCl over strongly heated amorphous Fe_2O_3 (Deville & Troost, *C R* 45, 821)—5 By heating a mixture of calcined FeSO_4 with CaCl_2 or NaCl The product obtained by boiling down a solution of Fe_2O_3 in HCl always contains oxychloride

Preparation—Fine iron wire is strongly heated in a hard glass tube in a stream of dry Cl, and the product is sublimed in the same gas

To prepare a solution of FeCl_3 , hydrated Fe_2O_3 is dissolved in hot HClAq , the solution is decanted, Cl is passed in until K_2FeCl_6 ceases to give any trace of blue colour, and excess of Cl is removed by warming, or 2 parts warm HClAq are saturated with Fe (filings or wire), to the clear decanted liquid 1 part HClAq is added, the liquid is warmed and HNO_3Aq is added little by little until all FeCl_2 is oxidised to FeCl_3 , excess of HNO_3 is removed by evaporation with a little HClAq Geissler (*Ar Ph* [2] 58, 159) recommends to evaporate the ferrous solution to S G 1.3 at 17° and then to add HNO_3Aq to the cold solution, when oxidation proceeds rapidly

Properties—By slowly cooling the vapour, FeCl_3 condenses in hexagonal crystals which appear very dark red by transmitted, and greenish by reflected, light (Deville & Troost, *C R* 45, 821) As ordinarily prepared FeCl_3 forms a brownish black crystalline mass Volatilises at somewhat over 100° Melts at $306^\circ - 307^\circ$ in a sealed tube (Carnelley & Williams, *C J* 37, 126) Deliquescent, conc solution in water is dark brown and somewhat viscid, it becomes limpid and yellow on dilution, a very dilute solution is colourless when cold (v *Reactions*, No 4)

Franz (*J* pr [2] 5, 283) gives the following table showing S G and percentage composition of FeCl_3Aq at 17.5° —

S G	p.c. FeCl_3	S G	p.c. FeCl_3	S G	p.c. FeCl_3
1.0146	2	1.1746	23	1.3870	42
1.0292	4	1.1950	24	1.4118	44

1.2318	24.60		

FeCl_3 is soluble in alcohol or ether, the solution

easily decomposes in sunlight with formation of FeCl_2 .

Molecular weight of gaseous ferric chloride. — Deville a Troost (*C R* 45, 821) found the V D of ferric chloride at 440° to be 162.7, this corresponds to the formula Fe_2Cl_3 . Grönwald a V Meyer (*B* 21, 687) made a series of determinations of V D, in an atmosphere of N, with the following results 151.75 at 448° (mean of 4), 138.5 at 518° (mean of 3), 121.3 at 606° (mean of 6), 78.66 at 750° (mean of 2), 71.2 at 1036° , 77.6 at 1077° , 4.8 at 1300° . These numbers seem to indicate a gradual resolution of molecules of Fe_2Cl_3 into FeCl_3 , none of the results, however, agrees exactly with the value calculated for FeCl_3 (81.905), but this was to be expected, as G a M showed that even at 518° ferric chloride is partially resolved into FeCl_2 and Cl in an atmosphere of N. According to Friedel a Cratz (*C R* 107, 301) ferric chloride is not dissociated at 440° in an atmosphere of Cl. F a C made a series of determinations of V D in Cl, using a modification of Dumas' method, the results are appended — 165.1 at 321.6° , 180.4 at 325.2° , 174.2 at 356.9° , 171.5 at 357° , 168.7 and 163.5 at 412.2° . These values are all somewhat greater than 162.1, the value required by the formula FeCl_3 . The most probable conclusion from all the results seems to be that at high temperatures, c 700° and upwards, the vapour of ferric chloride consists of molecules of FeCl_3 , but that as temperature falls these molecules are mixed with more complex molecules, some of which at any rate have the composition Fe_2Cl_3 (cf Young, *N* 39, 195).

Reactions. — 1 When FeCl_3 is heated in oxygen, Fe_2O_3 and Cl are produced (cf Schulze, *J pr* [2] 21, 407). — 2 Heated in hydrogen, FeCl_2 is formed (Wohler, *A Suppl* 4, 255). — 3 Heated in water vapour, Fe_2O_3 and HCl are formed. — 4 FeCl_3 dissolves in water, the conc solution is a syrupy dark brown liquid, becoming yellow on dilution, and colourless when very dilute and cold. By heating FeCl_3 aq, colloidal soluble Fe_2O_3 , $x\text{H}_2\text{O}$ and HCl are produced, fairly conc FeCl_3 aq forms oxychlorides, Fe_2O_3 , $x\text{FeCl}_3$, at c 100° , and at higher temperatures Fe_2O_3 is formed. The amount of decomposition and the composition of the products depend on the concentration of the solution and the temperature, very dilute solutions, c 30,000 water to 1 FeCl_3 , are decomposed with formation of colloidal soluble ferric hydrate even without warming (cf Ivor, *hydrated oxides or hydroxides of p 59*). Krecke (*J pr* [2] 3, 286) gives the following table (cf Tichborne, *C N* 24, 123 199, 209, 230, 25, 133, Muller, *J* 1873 40, Fous sereau, *C R* 103, 42) —

FeCl_3 aq containing $\frac{1}{10}$ p.c. FeCl_3 or less is decomposed by light at 5° – 6° (Krecke, *lc*). When FeCl_3 aq is heated in a sealed tube to 250° – 300° it decomposes to Fe_2O_3 and HCl (Senarmont, *C R* 32, 762). From a very dilute cold colourless solution of FeCl_3 , K_2FeCl_6 aq ppts a pure bl. e pp., and NaCl produces no change. If the solution is heated it becomes yellow, and contains soluble ferric hydrate and HCl. From this solution K_2FeCl_6 aq ppts greenish blue solid, and on addition of NaCl a soluble ferric hydrate separates, which, after long contact with NaCl aq, becomes insol in water (Debray, *C R* 68, 913). Evaporation of FeCl_3 aq is accompanied by evolution of some HCl, the residue contains oxychloride or hydrated oxide FeCl_3 is not volatilised from violently boiling FeCl_3 aq containing HCl (Fresenius, *Fr* 6, 92). G Wiedemann connects the decomposition of FeCl_3 aq, and also of other ferric salts, with the different magnetic behaviour of colloidal soluble Fe_2O_3 , $x\text{H}_2\text{O}$, and that hydrate which remains in combination with the acid (*W* 5, 45). — 5 FeCl_3 dissolves in alcohol or ether. An ethereal solution mixed with alcohol and allowed to stand in sunlight loses its yellow colour, and FeCl_3 and chlorinated derivatives of alcohol and ether are formed. — 6 An aqueous solution of FeCl_3 is readily reduced to FeCl_2 , e.g. by As, Sb, Bi, Fe, Pb, or Zn, also by finely divided Pt, more slowly by Pd and Au (cf Béchamp, *C R* 52, 757, Saint Pierre, *C R* 54, 1077). Also reduced by stannous chloride, sulphurous acid, or sulphuretted hydrogen, hydriodic acid reduces dilute FeCl_3 aq slowly (v Mohr, *A* 105, 53). Many organic compounds also reduce FeCl_3 aq, especially in sunlight, e.g. alcohol and ether, or tartaric acid (v Schorax, *B* 3, 11, Poitevin, *C R* 52, 94). — 7 A very little FeCl_3 is said to be formed by passing hydrogen for 48 hours through FeCl_3 aq (Brunner, *J* 1864 125). — 8 FeCl_3 dissolves freshly ppd ferric hydrate forming oxychlorides (q.v.). — 9 When FeCl_3 aq is dropped into solution of potassium nitrite, in an atmosphere of CO, brisk evolution of NO proceeds, and a pp of soluble ferric metahydroxide, Fe_2O_3 , H_2O , separates (Pesci, *G* 18, 183). — 10 FeCl_3 aq reacts with potassium iodide to form FeCl_2 , I, and KCl, probably FeI_3 is at first produced, and is then resolved into FeI_2 and I, and then the FeI_2 reacting with unchanged FeCl_3 forms FeCl_2 and I (v Carnegie, *C N* 60, 87). — 11 When electrolysed, conc FeCl_3 aq gives FeCl_2 at the negative, and Cl with a little O at the positive, electrode.

Combinations. — 1 With water to form various hydrates (1) FeCl_3 , $6\text{H}_2\text{O}$, yellow solid, formed by dissolving 100 parts FeCl_3 in 63.5 parts H_2O (S.G. of solution 1.67 at 25°), or by slowly eva-

FeCl_3 re formed on cooling

FeCl_3 not re formed on cooling

porating FeCl_2 aq on the water bath, and allowing to crystallise, or by exposing FeCl_2 to the air (Mohr, *A* 29, 178), or by passing HCl over commercial ferric chloride, filtering the liquid which forms through glass wool, and evaporating over KOH *in vacuo* (Engel, *C R* 104, 1708), melts at 35.5° , and solidifies again at 28° (Ordway, *Z* 1866 23) (2) $2\text{FeCl}_2 \cdot 5\text{H}_2\text{O}$, reddish tablets, melting at 81° , formed by melting the hexahydrate, warming to 100° , for some hours, and cooling slowly (Engel, *l c*), or by evaporating FeCl_2 aq to a syrup (SG c 15), with addition of a little HCl aq, and crystallising (Fritzsche, *J pr* 18, 479, Goble, *J Ph* [3] 5, 301, 25, 259) According to Wittstein (*R P* [2] 36, 30) and Ordway (*Z* 1866 23), the hydrate thus obtained is $\text{FeCl}_2 \cdot 3\text{H}_2\text{O}$. The hydrate $2\text{FeCl}_2 \cdot 5\text{H}_2\text{O}$ is said to be formed by placing $\text{FeCl}_2 \cdot 6\text{H}_2\text{O}$ over H_2SO_4 , the hexahydrate at first liquefies and then loses water—2 With *hydrogen chloride and water*, to form $\text{FeCl}_2 \cdot \text{HCl} \cdot 2\text{H}_2\text{O}$, thin, transparent, amber yellow laminae, formed by passing dry HCl gas over $2\text{FeCl}_2 \cdot 5\text{H}_2\text{O}$, saturating the liquid thus produced with HCl at 25° , and cooling to 0° (Engel, *C R* 104, 1708, Sabatier, *Bl* 1881 197)—3 With *ammonia*, to form $\text{FeCl}_2 \cdot \text{NH}_3$. When heated, this compound partly sublimes, and is partly decomposed, giving FeCl_2 —4 With *phosphoric chloride*, to form a brown fusible compound, $\text{FeCl}_2 \cdot \text{PCl}_3$ (Weber, *J pr* 76, 410)—5 With *hydrocyanic acid*, to form a brown liquid, which then crystallises to $\text{FeCl}_2 \cdot 2\text{HCN}$ (Klein, *A* 74, 87)—6 With *cyano gen chloride*, but the compound has not been obtained pure (v Klein, *l c*)—7 With *nitrosyl chloride*, to form $\text{FeCl}_2 \cdot \text{NOCl}$, a dark coloured, very deliquescent mass, obtained by placing dry FeCl_2 in the fumes of *aqua regia* placed over CaCl₂ (Weber, *J pr* 89, 152)—8 With *alkali chlorides*, to form $\text{FeCl}_2 \cdot 2\text{MCl} \cdot \text{H}_2\text{O}$, $\text{M} = \text{K}, \text{Na}, \text{Rb}, \text{NH}_4$. The NH_4 compound forms garnet red crystals, by evaporating mixed solutions of the constituent salts. The crystals are rhombic according to Fritzsche (*J pr* 18, 484), dimorphous according to Gentz (*J pr* 71, 164). The double compounds $\text{FeCl}_2 \cdot 2\text{MCl} \cdot \text{H}_2\text{O}$ are all decomposed by water. The K salt is described by Fritzsche (*J pr* 18, 483), the Na salt by Deville (*C R* 43, 970), the Rb salt, said to be $\text{FeCl}_2 \cdot 3\text{RbCl}$, by Godeffroy (*Ar Ph* [3] 9, 343) According to Kremers (*J pr* 55, 191), a compound of the form $\text{FeCl}_2 \cdot 2\text{MCl} \cdot \text{H}_2\text{O}$, in which M is partly K (12.1 p c), partly Na (16 p c), and partly NH_4 (6.2 p c), is found in certain volcanic craters—9 With *thallium chloride*, to form $\text{FeCl}_2 \cdot 3\text{TlCl}$ (Wöhler, *A* 144, 250)—10 With *magnesium and beryllium chlorides*, to form $\text{FeCl}_2 \cdot \text{MCl}_2 \cdot \text{H}_2\text{O}$, formed by adding MgCl_2 or BeCl_2 to a conc hot solution of FeCl_2 in HCl aq (Neumann, *A* 244, 328)

FEROUS FERRIC CHLORIDE Fe_2Cl_3 ($\text{FeCl}_2 \cdot 2\text{FeCl}_3$) When $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is treated with a little HCl aq, FeCl_2 goes into solution, and Fe_2O_3 remains, but $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ dissolves wholly in considerable excess of conc HCl aq. When the solution is cooled and placed *in vacuo* over H_2SO_4 , yellow crystals of $\text{Fe}_2\text{Cl}_3 \cdot 18\text{H}_2\text{O}$ are said to separate (Lefort, *C R* 69, 179). The crystals are deliquescent, at 50° they lose water, heated to 90° HCl is given off and O absorbed, by warming an aqueous solution of the crystals, FeCl_2 and FeCl_3 are formed.

Iron, cyanides of. No cyanides of iron have been isolated, but *ferric* and *ferro cyanides* are numerous, v vol ii pp 332, 334, 338

Iron, ferricyanide and ferrocyanide of, v vol ii pp 334 a 338

Iron, fluorides of. Two fluorides of Fe are known, FeF_2 and FeF_3 . The former is produced by dissolving Fe in HFAq, the latter by dissolving $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HFAq

FEROUS FLUORIDE FeF_2 . Small green crystals of this composition separate from a solution of Fe in HFAq (Scheurer Kestner, *A Ch* [3] 68, 472). By careful heating, FeF_2 is obtained as a white solid. FeF_2 is unchanged by heat, the hydrate is partly decomposed to HF and Fe_2O_3 . Slightly sol in water, more easily on addition of HF. The double salt $\text{FeF}_2 \cdot 2\text{KF}$ is a green pp, obtained by adding KF aq to FeSO_4 aq, the salts $\text{FeF}_2 \cdot \text{KF} \cdot 2\text{H}_2\text{O}$, $\text{FeF}_2 \cdot 2\text{NH}_4\text{F}$, and $\text{FeF}_2 \cdot \text{NH}_4\text{F} \cdot 2\text{H}_2\text{O}$ are described by Wagner (*B* 19, 896). The *Silicofluoride* $\text{FeF}_2 \cdot \text{SiF}_4$ ($= \text{FeSiF}_6$) is said to be formed as blue green crystals by dissolving Fe in H_2SiF_6 aq and crystallising (Wurtz, *Dictionnaire*, 1 1408)

FERRIC FLUORIDE FeF_3 . Crystals of the hydrate $2\text{FeF}_3 \cdot 9\text{H}_2\text{O}$ are obtained by dissolving $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HFAq and evaporating, or by oxidising FeF_2 in HFAq by HNO_3 . The crystals are yellowish according to Berzelius, colourless according to Scheurer Kestner (*A Ch* [3] 68, 472). At 100° $3\text{H}_2\text{O}$ is removed, at higher temperatures H_2O and HF escape. By heating the salt dried at 100° in a Pt crucible colourless crystals of FeF_3 are formed on the surface of the mass, isomorphous with AlF_3 (Deville, *C R* 43, 970). Slowly dissolved by water, addition of NH_4Aq ppt the *oxyfluoride* $3\text{Fe}_2\text{O}_3 \cdot 2\text{FeF}_3 \cdot 4\text{H}_2\text{O}$. FeF_3 forms double salts with K, Na, and NH_4 , these are obtained by adding FeF_3 aq to solutions of the alkali fluorides, the salts described are $\text{FeF}_3 \cdot 3\text{KF}$ (Berzelius, Wagner, *B* 19, 896), $2\text{FeF}_3 \cdot 4\text{KF} \cdot \text{H}_2\text{O}$ (Nicklès, *Z* 7, 480), $\text{FeF}_3 \cdot 3\text{NaF}$ (B, W, *l c*), $\text{FeF}_3 \cdot 2\text{NaF}$ (Nicklès, *J* 1869 268), $\text{FeF}_3 \cdot 2\text{NH}_4\text{F}$ (N, *l c*), to this salt Mangano gives the formula $\text{FeF}_3 \cdot 3\text{NH}_4\text{F}$ (*A Ch* [3] 60, 306)

Iron, haloid compounds of. Iron readily combines with the halogens. With each halogen, two compounds are formed, ferrous FeX and ferric FeX_3 , ferric iodide, however, has not been isolated with certainty, the compound Fe_2Cl_6 , corresponding to Fe_2O_3 , also perhaps exists. The only compounds that have been gasified are ferrous and ferric chloride. The former has the molecular formula FeCl_2 at 1300° – 1500° , but there are indications of the possible existence of molecules of Fe_2Cl_4 at lower temperatures, the latter appears to exist as a gas both as Fe_2Cl_6 and FeCl_2 . The haloid compounds of Fe are soluble in water, solutions of FeBr_3 and FeCl_3 are decomposed by much water, the compounds all form several double compounds with the chlorides &c of the more positive metals

Iron, hydrides of. No definite hydride of Fe has been certainly isolated, but there are several indications of the existence of a compound or compounds of Fe and H. Fe heated to redness absorbs about 46 vols H (Deville, *A* Troost, *C R* 57, 965, 59, 102). Electrolytically deposited Fe contains H along with N, CO, and CO_2 (Lenz, *P. Ergänzbd* 5, 252, cf Meidinger,

D P J 163, 288, Chandler Roberts, *C N* 31, 137, Iron was takes up H when immersed in dilute $\text{H}_2\text{SO}_4\text{Aq}$ (Johnson, *Pr* 23, 168, Reynolds, *C N* 29, 118) According to Caillaet (*C R* 80, 319) Fe npd electrolytically from neutral FeCl_2Aq containing NH_4Cl gives off 235-238 vols H when heated *in vacuo* Observations on the supposed existence of a gaseous hydride of Fe were made by Thomson, Dupasquier (*C R* 14, 511), and Reinsch (*J* 1858 '90) The non existence of such a gas was proved by Fresenius a Schlossberger (*A* 51, 415) and by Erlemeyer (*N J P* 9, 97) Thoma has investigated the conditions under which H is absorbed by Fe (*Z P C* 3, 91) He finds that when Fe is made the negative electrode in a voltameter, or when it is placed in dilute $\text{H}_2\text{SO}_4\text{Aq}$, it absorbs much H, but that Fe placed in an atmosphere of H does not absorb any of that gas, a certain portion of the H absorbed is given off again on exposure to air or immersion in water, the rest of the H is more firmly retained by the Fe According to Wanklyn a Carus (*A* 120, 69) when Fe_2 reacts with ZnEt , in presence of ether, various gases including C_2H_4 , CH_4 , C_2H_6 , and H are evolved, and a metal like powder remains, which, after washing with ether, is decomposed by H_2O giving H and a mixture of H and FeO They regard this powder as a hydride of Fe, perhaps FeH_2 , but no analyses are given

Iron, hydrated oxides or hydroxides of Compounds with water of each of the three oxides of iron are known The compositions of the various hydrated oxides are differently represented by different chemists they appear to vary with small changes of conditions, so that it is impossible to say whether all the bodies described are true hydrates or not The readiness with which most of the hydrated oxides undergo change of composition points to their being hydrates, i.e. compounds of water, rather than hydroxides, i.e. compounds of OH Thomson (*Th* 3, 293) gives the thermal data $-(\text{Fe}, \text{O}^2, 3\text{H O}) = 191,140$, $-(2\text{FeO H}^2, \text{O}, \text{H O}^2) = 54,590$, $[(\text{Fe}, \text{O}, \text{H O}) = 68,280$, $[(\text{FeO H}, \text{H SO}^2\text{Aq}) = 24,920$, $[(\text{Fe}^2\text{O}^2\text{H}^2, 3\text{H SO}^2\text{Aq}) = 33,840$

Only one hydrate of ferrous oxide, FeO H O , appears to exist, but it is doubtful whether any hydrate of this oxide has been obtained free from hydrates of Fe_2O_3 Descriptions are given of two hydrates of ferrous ferric oxide, viz $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ and $\text{Fe}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$, but here again there is great doubt as to the composition of the substances described as definite hydrates Many hydrates of ferric oxide have been obtained, the following are known as minerals ($\text{M} = \text{Fe}_2\text{O}_3$) $\text{M H}_2\text{O}$, $\text{M 2H}_2\text{O}$, $\text{M 3H}_2\text{O}$, $\text{2M H}_2\text{O}$, $\text{2M 3H}_2\text{O}$, $\text{3M 5H}_2\text{O}$, the following are said to have been obtained artificially $\text{M H}_2\text{O}$, $\text{M 2H}_2\text{O}$, $\text{M 3H}_2\text{O}$, $\text{2M H}_2\text{O}$, $\text{2M 3H}_2\text{O}$, many of these appear to exist in different modifications each distinguished by special properties, broadly they fall into two classes, those which are insoluble in water, and those which dissolve in water

HYDRATE OF FERROUS OXIDE $\text{FeO H}_2\text{O}$ The white pp obtained by adding air-free KOH Aq to an air free solution of a ferrous salt, and washing out of contact with air, is probably $\text{FeO H}_2\text{O}$ To obtain the pp nearly free from ferric oxide Schmidt (*A* 86, 101) pptts in a closed flask,

allows pp to settle, draws off water by a syphon, carefully pours warm water which has been boiled for some time on to the surface of the cold water in the flask, withdraws water by a syphon, &c., he then quickly transfers the moist pp by a syphon to a retort containing ether, and having attached to it a long glass tube dripping under Hg, the ether covers the pp and drives the air out of the retort, on warming, the water vapour and condensed water escape through the Hg When the ether is removed and the retort is cold, dry air free H (not CO, as the hydrate combines with this gas) is passed through the apparatus, and portions of the solid are transferred in an atmosphere of H to small wide mouthed stoppered tubes Dried in this way, the hydrate is a pale greenish, friable solid, which rapidly oxidises and glows in the air

A de Schulten (*C R* 109, 266) states that $\text{FeO H}_2\text{O}$ may be obtained in green six sided flat prisms, which almost instantly become red in air, by mixing 5 grams FeCl_2 dissolved in 100 c.c. air free water, and 200 c.c. NaOH Aq , containing 20 grams NaOH , in a flask filled with coal gas, heating, and allowing to stand for 24 hours

According to Bineau (*C R* 41, 509) ferrous hydrate is soluble in c. 150,000 parts water Ferrous hydrate is very easily oxidised, it is therefore an energetic reducer, e.g. it reduces salts of Au, Ag, and Pt, and also HIO_4Aq It dissolves in acids to form ferrous salts FeX_2 ,

$\text{X} = \text{NO}_3, \text{SO}_4, \text{PO}_4, \text{ \&c (cf Ferrous oxide,}$

under Iron, oxides of)

HYDRATES OF FERROUS FERRIC OXIDE

$\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ and $\text{Fe}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$, a composition of both doubtful Hydrates of Fe_2O_3 are produced by ppg a mixture of equivalent quantities of a ferrous and ferric salt by alkali, and also by digesting ppg $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ with Fe The black powder obtained by Wöhler (*A* 28, 92), by ppg a mixture of equivalent parts of ferrous and ferric sulphates by slight excess of NH_4Aq , boiling, washing by decantation, and drying under 100° is said by Lefort (*C R* 69, 179) to be $\text{Fe}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$ By ppg a mixture of equivalent quantities of a ferrous and ferric salt by hot conc KOH Aq , Lefort (*lc*) obtained a hydrate more stable than that got by using NH_4Aq , to this hydrate he gives the formula $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ The black hydrate obtained by digesting $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ with Fe under water does not seem to have been analysed (v. Preuss, *A* 26, '96) Ferrous ferric hydrates are described as brown black, magnetic, brittle, powders, when heated out of contact with air they give Fe_2O_3 , heated in air, Fe_2O_3 is produced Ferrous ferric hydrates dissolve in acids to produce mixtures of ferrous and ferric salts, in some cases definite salts of the form Fe_2X_3 , $\text{X} = \text{SO}_4$, &c., are formed, according to Lefort (*C R* 69, 179) (cf Ferrous-ferric oxide, under Iron, oxides of)

HYDRATES OF FERRIC OXIDE A great many supposed hydrates of Fe_2O_3 have been described, but there is much doubt as to the composition and properties of definite hydrates of the form $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ The following occur as minerals, the compositions of which more or less accurately agree with the formulae—limonite $\text{Fe}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, $\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, and $2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$;

göthite $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$, *turgite* $2\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ and $3\text{Fe}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$. According to Ramsay (*C J* 32, 895), and Bresscius (*J pr* [2] 3, 272), the pp obtained by adding alkali to a ferric salt, either hot or cold, washing, and drying at 100° , is $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$, by ppg FeCl_3Aq with NH_4Aq , washing first with water and then with alcohol and ether, and drying at 100° the hydrate $\text{Fe}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ is obtained, according to Bresscius (*lc*) Wittstein (*C C* 1853 367) says that the hydrate obtained by ppg a ferric salt by NH_4Aq , washing with cold water, and drying at a gentle heat, or at 100° for a short time, is $\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$. The experiments of Carnelley & Walker (*C J* 53, 89) on the dehydration of ppd $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ through a range of temperature showed that the pp after drying at 15° for 18 days contained more water than is required by $\text{Fe}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$, that when heated to 55° the residue had the composition $\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, but that water was gradually and continuously given off from 15° upwards until Fe_2O_3 was formed at 500° , the composition, however, remained constant from 385° to 415° , and corresponded with the formula $10\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. Van Bemmelen (*R T C* 7, 106) has examined the composition of the colloidal pp by adding NH_4Aq to FeCl_3Aq , his experiments, which were very extended, showed the great readiness with which the ratio of Fe_2O_3 to H_2O varies, *e.g.* exposed to air for a year the composition became constant with the ratio $\text{Fe}_2\text{O}_3 \cdot 4$ or $4\text{H}_2\text{O}$, after 4 months in dry air the ratio was $\text{Fe}_2\text{O}_3 \cdot 1.6\text{H}_2\text{O}$, heated to 100° in dry air the ratio was $\text{Fe}_2\text{O}_3 \cdot 96\text{H}_2\text{O}$, the same sample kept for 6 years in a closed flask and then heated to 15° until constant gave $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$, at 100° $\text{Fe}_2\text{O}_3 \cdot 45\text{H}_2\text{O}$, between 100° and 300° the final state was $\text{Fe}_2\text{O}_3 \cdot 25\text{H}_2\text{O}$, and so on. Besides the papers referred to above on the composition of ppd. $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, the following are of importance.—Lefort (*J pr* 54, 305), P de Saint Gilles (*J pr* 66, 137), Schaffner (*A* 51, 177), Muck (*Z* [2] 4, 41), Davies (*C J* [2] 4, 69), Tommasi (*B* 12, 1929, 2334).

The *monohydrate* $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is said to be obtained (1) by adding NaOH Aq and KClO Aq to boiling FeSO_4Aq , washing, and drying at 100° (Muck, *Z* [2] 4, 41), (2) by keeping ppd $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in contact with boiling water for 6-8 hours (P de Saint-Gilles, *A Ch* [3] 46, 47), (3) by repeatedly melting NaOH in a cast iron vessel and washing (Brunck & Gräbe, *B* 13, 725), (4) by keeping ppd $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ under water for many years at the ordinary temperature (Schiff, *C C* 1860 1768). This hydrate also occurs native as *göthite* $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is described as a dark-red powder, slowly dissolved by dilute warm HCl Aq , $\text{H}_2\text{SO}_4\text{Aq}$, or HNO_3 , insol in cold conc acids. The monohydrate obtained by Brunck & Gräbe was in the form of small tabular, brownish-violet, hexagonal crystals, SG 2.91. Göthite forms rhombic crystals, SG 3.8 to 4.2. The monohydrate obtained by Péan de Saint-Gilles, by keeping $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in contact with boiling water for 6-8 hours, is described as a brick-red powder, scarcely acted on by conc boiling HNO_3Aq , slowly dissolved by conc hot HCl Aq , it dissolves in dilute HNO_3Aq , HCl Aq , or acetic acid, forming a red liquid which appears clear by transmitted, but

turbid by reflected light, and is ppd by a very small quantity of an alkali salt, on addition of conc HNO_3Aq or HCl Aq , this solution gives a red pp which dissolves on adding water. This modification of $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ does not form Prussian blue with K_2FeCy_6 and acetic acid.

The *dihydrate* $\text{Fe}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ is said to be obtained by ppg cold FeSO_4Aq by NaOH Aq and KClO Aq or $\text{H}_2\text{O Aq}$, washing, and drying at 100° (Weltzien, *A* 138, 126, Muck, *lc*). This hydrate also occurs native as *limonite*.

The *hydrates* $2\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ and $2\text{Fe}_2\text{O}_3 \cdot 8\text{H}_2\text{O}$ are said to be formed by the action of water on ppd $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, the first by boiling for 100 to 1,000 hours, Davies (*C J* [2] 4, 66), the second by long continued action of water at the ordinary temperature (Wittstein, *Ar Ph* 74, 158), or, crystalline, by freezing $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ suspended in water (Lamberger, *C C* 1853 783). By heating any of the hydrates in sealed tubes Fe_2O_3 is eventually produced (Sénarmont, *C R* 32, 762).

Muck (*Z* 1868 41) thinks that the ferric hydrates obtained by oxidising ferrous hydrate or carbonate in air differ essentially in properties from the ferric hydrates obtained directly from ferric salts. Tommasi (*Bl* [2] 38, 152, T a Pellizzari, *Bl* [2] 37, 196) arranges the ferric hydrates in two classes the red hydrates obtained by ppg ferric salts by alkali, and the yellow hydrates obtained by oxidising hydrates of FeO or Fe_2O_3 , or by oxidising FeCO_3 .

Ferric hydrates give up O to readily oxidised compounds such as SO Aq , SnCl_2Aq , in contact with decaying organic bodies the hydrates part with O, but again take it up if exposed to air, they absorb gases *e.g.* NH_3 and CO_2 (v Reinhardt, *Fr* 7, 187). They dissolve in acids to form ferric salts FeX , $\text{X} = \text{NO}_3$, $\frac{\text{SO}_4}{2}$, $\frac{\text{PO}_4}{3}$ &c

These hydrates when freshly ppd also dissolve in FeCl_3Aq forming oxychlorides (*q v*) (*v Ferric oxide*, under *Iron*, *oxides of*, p 62).

SOLUBLE FERRIC HYDRATES. A modification of $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ soluble in water was prepared by P de Saint Gilles in 1855 (*A Ch* [3] 46, 47). Ordinary ppd $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ is dissolved in acetic acid, the solution is heated to 100° for a long time in a closed vessel, the blood red colour of the liquid changes to brick red, the liquid appears opalescent in reflected light, and the taste is no longer metallic but merely that of acetic acid, on now adding conc HCl Aq or HNO_3Aq , or the merest trace of $\text{H}_2\text{SO}_4\text{Aq}$ or an alkali salt, the whole of the Fe is thrown down as a brown red curdy pp, which, when dried on a porous tile, appears as a brown, lustrous, varnish like solid, having the composition $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. This modification of ferric hydrate, sometimes called *ferric metahydrate*, is insol in conc acids, but dissolves easily in water, forming a deep-yellow, opalescent, tasteless liquid, unchanged by K_2FeCy_6 , or KCNS . Traces of H_2SO_4 or alkali salts, and also conc HCl Aq or HNO_3Aq , ppt the hydrate from its aqueous solution. The same hydrate has been obtained by Soheuer & Kestner by prolonged heating an aqueous solution of basic ferric nitrate in a sealed tube at 190° (*C R* 48, 1160), also by Debray by heating dilute FeCl_3Aq to 100° (*C R* 68, 913, *cf. Ferric chloride*, *Reactions*,

No 4, p 55) Another soluble modification of ferric hydrate, sometimes called *dialysed* or *colloidal ferric hydrate*, is obtained by dialysing a solution of FeCl_3 containing $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ so long as the dialysate contains HCl (Graham, *Tr* 1861 183) The solution is prepared by digesting FeCl_3Aq with $\text{ppd Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, or by adding $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ to FeCl_3Aq so long as the pp dissolves on stirring, the solution should contain 4-5 p.c. of solid matter, and have 5-6 equivalents of ferric hydrate in it After dialysis a deep red liquid is left on the dialyser, this liquid gelatinises by exposure to the air for some days, or by traces of H_2SO_4 , alkalis, alkaline salts, but not by HCl , HNO_3 , or acetic acid, the jelly like mass thus obtained slowly becomes insol in water, and is then sol in dilute acids, it appears to be changed to the ordinary $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ (Graham *Le*, cf Shuttlesworth, *Ph* [3] 8, 545, Becquerel, *A* 126, 208)

Krecke (*J pr* [2] 3, 286) has examined the formation of soluble ferric hydrates from FeCl_3Aq Formation of the colloidal hydrate occurs in FeCl_3Aq containing $\frac{1}{10}$ to $\frac{1}{2}$ p.c. FeCl_3 at ordinary temperatures, solutions containing 8 to 32 p.c. must be heated to above 100° in closed tubes, on cooling the more conc solutions (if not heated too long and too highly) re formation of FeCl_3 occurs, but in solutions of less than 1 p.c. the base and acid remain uncombined on cooling If a solution containing less than 1 p.c. is boiled for some time formation of ferric metahydrate begins, and after a time the hydrate is ppd as an orange yellow powder A table showing the various products obtained by heating solutions of FeCl_3Aq of different concentrations to different temperatures is given under *Ferric chloride, Reactions*, No 4 (p 55)

Iron, iodides of Only one iodide of iron, FeI_3 , has been isolated with certainty

FERRIC IODIDE (Proto iodide of iron) FeI_3 , H F [FeI_3Aq] = 47.650 (*Th* 3, 294) Fe and I combine by rubbing together with or without water, Fe and I heated together form a crystal line grey mass which melts at 177° (Carius a Wanklyn, *A* 120, 69) According to De Luca FeI_3 is white, but goes green on addition of water (*C R* 55, 615) Green deliquescent crystals of $\text{FeI}_3 \cdot 5\text{H}_2\text{O}$, SG 2873, are obtained by digesting 1 part Fe filings with 3 4 parts I in presence of water, adding Fe filings, evaporating out of contact with air, and filtering FeI_3 , especially FeI_3Aq , rapidly absorbs O with formation of oxyiodide (*q v*) Addition of sugar syrup to FeI_3 renders the solution more stable $\text{H}_2\text{O}_2\text{Aq}$ decomposes FeI_3 with formation of $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ and separation of all the I FeI_3Aq dissolves I, addition of K_2CO_3 to a solution containing 3 FeI_3 , 21 forms KI and $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, the solution may contain FeI_3

FERRIC IODIDE (FeI_3) This iodide has not been isolated, it is probably contained in a solution of FeI_3 to which I is added in the ratio FeI_3 , I. FeI_3Aq containing I is separated by heating to FeI_3 and free I Fleury (*J Ph* [5] 16, 529) says that the action of I on Fe in presence of water soon ceases if the temperature is kept down to 15° , on filtering, only Fe is obtained, if, however, the mixture is boiled the red colour of the liquid disappears and a considerable quantity of Fe_2O_3 is found in the re-

sidue A large excess of I is required to dissolve all the Fe, and a large excess of Fe is required to convert all the I into FeI_3 F supposes that FeI_3 is at first formed and is then decomposed by the heat to Fe_2O_3 and HI, and the HI then acts on the free Fe forming FeI_3 , Mohr observed that a very dilute solution of FeCl_3 (1 in 12,300) gives a blue colour on addition of starch and KI only after a considerable time (*A* 105, 53) Nicklés found that a solution of $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HIAq in presence of ether did not at once give a blue pp with K_3FeCy , (*A Ch* [4] 5, 161, cf Ordway, *Am. S* [2] 26, 197) A solution made by digesting 126 parts I with sufficient iron, filtering, and adding 63 parts I, gives an apple green pp on addition of 201 parts citric acid previously neutralised by alkali carbonate (Creuse, *Ph* [3] 3, 953) According to Carius a Wanklyn (*A* 120, 70) if Fe is heated with excess of I until a little I is vapourised, and the mass is allowed to cool in a covered crucible, I is suddenly evolved, and the residue consists of FeI_3

Iron, nitrides of A nitride of Fe, Fe_3N_2 , is found as a silver like lustrous deposit in the lavas of Lina (Silvestri, *P* 157, 165), heated in H it yields Fe and NH_3 Finely divided Fe, prepared by heating ferrous oxalate or reducing Fe_2O_3 by H, takes up about 2 p.c. N when heated in N (Geuther a Briegleb, *A* 133, 228, Rogstadus, *J pr* 86, 307, Remsen, *Am* 3, 134) By heating Fe in NH_3 the Fe increases in weight 12-13 p.c. and becomes brittle (Berthollet, *G* 4 30, 378) By electrolysis a mixture of NH_4Cl and a ferrous salt a lustrous deposit is obtained, supposed by Kramer to be a nitride of Fe with 15 p.c. N (*Ar Ph* [2] 106, 284), but said by Meidinger (*D P J* 163, 283) to be an FeNH_3 amalgam A nitride (or nitrides) of iron seems to be produced by heating FeCl_3 or FeCl_2 in NH_3 The product is a brittle, grey white, solid, heated alone it gives N and Fe, heated in H it gives NH_3 and Fe, it is slowly and partially decomposed by boiling water, sol. in acids with formation of H, ferrous and NH_3 salts, not acted on by Cl, Br, or I in presence of H O at ordinary temperatures, but when heated ferric and NH_3 salts are formed, and H, and probably also N, are evolved The formula Fe_3N_2 agrees with most of the analyses, the formula Fe_2N_3 was given by Stahlschmidt (*P* 125, 37, cf Rogstadus, *J pr* 86, 307, Fremy, *C R* 52, 321)

Iron, nitroprusside of, v vol. II p 340

Iron, nitrosulphides or nitrososulphides of. In 1858 Roussin obtained a salt by the reaction of NH_4HS and KNO_3 on FeCl_3Aq , which contained Fe, but in which Fe could not be detected by the ordinary tests (*A Ch* [3] 52, 285) Procznsky (*A* 125, 302) obtained the same compound by adding NH_4HS to a solution of a ferrous salt saturated with NO A similar salt was obtained by Pavel by using K_2S in place of NH_4HS (*B* 12, 1407) By treating these salts with alkali others were obtained more or less closely related to the original salts The compounds thus obtained were analysed and examined by Roussin (*l c*), Procznsky (*l c*), Rosenberg (*B* 3, 812, 12, 1715), Demel (*B* 12, 461), and Pavel (*B* 12, 1407, 1949, 15, 2600) Roussin's analyses of the compound formed by using

NH_4HS led to the formula $\text{Fe}_3\text{S}_2(\text{NO})_4$, to the same compound Proczinsky gave the formula $\text{Fe}_3\text{S}_2(\text{NO})_2 \cdot 2\text{H}_2\text{O}$, and Rosenberg assigned the composition $\text{Fe}_3\text{S}_2(\text{NO})_{10} \cdot 4\text{H}_2\text{O}$. In his second paper R. showed that the compound prepared by using K_2S contained K, this was confirmed by Pavel. All the observers admitted the presence of the NO group in these compounds.

Pavel (B 15, 2600) has given an account of the compounds of which Roussin's salt is the type, and has indicated what appear to be their relations to other compounds of iron. As the compounds contain the group NO in addition to S they are better called nitroso than nitrosulphides. Pavel regards the nitroso sulphides of Fe as salts of acids, the acidic radicals of which are composed of Fe, NO, and S, the salts may be formulated generally as derived from the acids $\text{H}_n\text{Fe}_x(\text{NO})_y\text{S}_z$. P. compares the *ferronitrososulphides* with the *ferronitrosocyanides* or *nitroprussides*, which are salts of $\text{HFe}(\text{NO})\text{Cy}$, (*v Nitroprussides*, vol. II p. 340). According to P. there are two series of ferronitrososulphides derived from the two acids $\text{HFe}(\text{NO})_2\text{S}_2$ (or $\text{H}_2\text{Fe}_2(\text{NO})_4\text{S}_4$) and $\text{HFe}(\text{NO})_2\text{S}$ (or $\text{H}_2\text{Fe}_2(\text{NO})_4\text{S}_2$). The former acid has been isolated, the latter is not as yet known in the free state. The two series may perhaps be called *ferrinitroso* and *ferronitrososulphides*. In the following account of the salts Pavel's formulæ are adopted —

Series I *Ferrinitrososulphides* $\text{MFe}(\text{NO})\text{S}_2$

Potassium ferrinitrososulphide $\text{KFe}(\text{NO})\text{S}_2$. A solution of KHS, made from 44 grams KOH in 400 c.c. water, is added to a boiling solution of 35 grams pure NaNO_2 in 400 c.c. water, the mixture is heated just to boiling, and a solution of 159 grams ferrous sulphate in 1200 c.c. water, to which a drop of dilute H_2SO_4 has been added, is allowed to flow into it with constant stirring, the liquid is kept warm on a water bath, and is shaken from time to time until a greenish red pp. (of Fe_2O_3 , FeO , and S) forms on the sides of the flask, when the liquid is rapidly filtered, a little dilute KOH aq. is added to it when cold, and it is allowed to stand for 48 hours. The salt which separates is dissolved in water at 70° , a little KOH aq. is added as the liquid cools, and the crystals thus obtained are recrystallised in the same way, after standing 48 hours; the crystals are then dried over H_2SO_4 *in vacuo* protected from the light. About 30 grams of the pure salt are thus obtained (Pavel, B 15, 2601). If more KHS is used than directed above double sulphides of Fe and K are obtained and no nitrososulphide.

$\text{KFe}(\text{NO})\text{S}_2$ crystallises in large, nearly black, lustrous, rhombic prisms, it is fairly stable in the air, decomposition begins at $c 115^\circ$ with evolution of NO, at $c 130^\circ\text{S}$, $(\text{NH}_4)_2\text{SO}_4$, NH_4NO_3 , &c. sublimes, heated in air H_2O , NO, N, SO_2 are evolved, and the residue consists of FeS , Fe_2O_3 , Fe_3O_4 , and K_2SO_4 , strong mineral acids evolve H_2S . Various metallic salts form metallic sulphides and NO, while Fe salts remain in solution, heated with alkali, crystalline Fe_2O_3 is ppd, NO evolved, and ferronitrososulphide $\text{KFe}(\text{NO})\text{S}$ is formed (Pavel, l.c.). $\text{KFe}(\text{NO})\text{S}_2$ is soluble in about 2 parts hot water, slightly sol. in cold water, very sol. with decomposition (Pavel, B.

12, 1410) in alcohol or ether, the salt is ppd by NH_4Aq or KOH aq . The salts of this series do not react with K_2FeCy_6 .

The following salts of this series have been isolated NH_4X , BaX , CsX (the most stable salt of the series), CaX_2 , FeX_2 , LiX , MgX_2 , RbX , TiX ($\text{X} = \text{Fe}(\text{NO})\text{S}_2$). The Na salt is formed similarly to the K salt, also by the reaction of Na_2CS_2 with NaNO_2 , the compound $\text{Fe}_3\text{S}_2(\text{NO})_4\text{CS}_2$ said by Low (C. C. 1865 548) to be formed in this reaction does not exist according to Pavel (B 15, 2603). For other reactions of the salts of the series *v* Pavel, B 15, 2604.

Ferrinitrososulphydic acid $\text{HFe}(\text{NO})_2\text{S}_2$ seems to be obtained by adding a slight excess of dilute H_2SO_4 aq. to a dilute solution of the Na salt, it is insol. in water, alcohol, and ether, sol. in CHCl_3 or CS. The acid has not been obtained pure (P, l.c.).

Series II *Ferronitrososulphides*
 $\text{MFe}(\text{NO})\text{S}$. These salts are formed by the action of dilute alkali solutions on the salts of Series I, in these reactions NO is evolved and FeO ppd, but NH_3 is not evolved except from the salt $\text{NH}_4\text{Fe}(\text{NO})\text{S}_2$. The salts of Series II are very unstable, they easily pass into Series I, the Cs salt is the most unstable of all, these salts are insol. in ether (except the Fe salt), CS_2 , and CHCl_3 , they decompose in the air with separation of S and Fe_2O_3 , and evolution of a little H_2S , the solutions then have an alkaline reaction, and contain salts of Series I along with alkaline nitrite and thiosulphate. If CO is passed into a solution of K_2FeCy_6 , and the K salt of Series II is then added, NO is evolved, S and Prussian blue are ppd., and the filtrate contains K_2FeCy_6 , and some KNO.

Potassium ferronitrososulphide
 $\text{KFe}(\text{NO})_2\text{S} \cdot 2\text{H}_2\text{O}$ is obtained by warming $\text{KFe}(\text{NO})_2\text{S}_2$ on the water bath with dilute KOH aq., washing, and drying *in vacuo* over H_2SO_4 and CaO in the dark, it is very unstable, and can be obtained approximately pure only with difficulty (P, B 15, 2606). By warming an alcoholic solution of $\text{KFe}(\text{NO})_2\text{S}$ with a considerable excess of EtI, quickly distilling, washing the residue first with water and then with aqueous alcohol, and crystallising from benzene, *ethyl ferronitrososulphide* $(\text{C}_2\text{H}_5)_2\text{Fe}(\text{NO})_2\text{S}$ is obtained in black, lustrous, monoclinic crystals (P, l.c.). For a discussion of the probable constitution of these nitrososulphides and a comparison of them with the nitroprussides *v* Pavel, B 15, 2613.

Iron, oxides. Three oxides of iron have been isolated, FeO , Fe_2O_3 , and Fe_3O_4 . The molecular weight of none is known with certainty, as none has been gasified. FeO and Fe_2O_3 are basic oxides, they produce salts by reactions with acids, of the forms FeX_2 and FeX_3 , $\text{X} = \text{Cl}$, NO_2 , $\frac{\text{SO}_4}{2}$, $\frac{\text{PO}_4}{3}$, &c., Fe_2O_3 also combines with some

more positive metallic oxides to form compounds $\text{Fe}_2\text{O}_3 \cdot x\text{M}^{II}\text{O}$, which are usually called *ferrites* (*v* vol. II p. 547). Fe_2O_3 reacts with acids to form both ferrous and ferric salts, FeX_2 and FeX_3 , according to Lefort a few salts corresponding with Fe_2O_3 are known, e.g. Fe_2Cl_3 , $\text{Fe}_2(\text{SO}_4)_3 \cdot 2\text{SO}_4 \cdot 15\text{H}_2\text{O}$ (*v Ferric ferric oxide*, p. 61). Besides the ferrites a series of *ferrates* is known (*v* vol. II p. 546), these salts are of

the form M^xFeO_x , they may be regarded as salts of the hypothetical ferrie acid H_xFeO_x , the anhydride of this acid would be Fe_2O_3 , this oxide of iron has not been isolated, but the corresponding oxide of Mn, MnO_2 , is known. All the oxides of Fe form hydrates (*v Iron, hydrated oxides of*, p 57) FeO very readily and rapidly absorbs O and changes to Fe_2O_3 , at a very high temperature Fe_2O_3 parts with O, and is reduced to Fe_3O_4 .

FEROUS OXIDE (*Protoxide of iron*) FeO This oxide cannot be obtained free from Fe_2O_3 , by pptn from ferrous salts and dehydrating the ppt.

Preparation—1 Pure Fe_2O_3 is heated to c 300° in a stream of pure H (Wackenroder a Stromeyer, *Ar Ph* 36, 27)—2 By heating ferrous oxalate out of contact with air (Liebig, *A* 95, 116, Moissan, *A Ch* [5] 21, 199)—3 By heating FeO for 20 minutes to c 500° in H or CO, or in CO at 440° for 6 hours (Moissan, *lc*) 4 By heating Fe in CO_2 to c 1000° (Moissan, *lc*)—5 By adding ferrous oxalate to boiling KOHAq (Böttger, *J pr* 76, 239)

Properties and Reactions—An ivory black powder. According to Moissan (*lc*) FeO obtained by heating ferrous oxalate, or reducing Fe_2O_3 in CO at 500° , is pyrophoric, burns to Fe_2O_3 , and decomposes water at ordinary temperatures, while the FeO obtained by heating Fe in CO_2 at c 1000° is non pyrophoric, burns to Fe_2O_3 , and does not decompose water at 100° . Siewert (*J* 1864 266) says that pyrophoric FeO , produced by reduction of Fe_2O_3 in H, becomes non pyrophoric by remaining in an atmosphere of H for 12 hours after cooling. FeO is readily oxidised to Fe_2O_3 (*cf* Moissan, *supra*). It dissolves in acids to form ferrous salts FeX_2 , $X = Cl, NO_3, \frac{SO_4}{2}$, &c

Combinations—The compound $FeO \cdot Al_2O_3$ occurs native as *hercynite*, and $FeO \cdot Cr_2O_3$ as *chrome ironstone*, magnetic oxide of iron may be regarded as $FeO \cdot Fe_2O_3$. The hydrate $FeO \cdot H_2O$ has been isolated (*v Hydrate of ferrous oxide*, p 57)

FEROUS FERRIC OXIDE (*Black or magnetic oxide of iron*) Fe_3O_4 . This oxide occurs native in large quantities as *magnetite*. According to Spring (*Bl* [2] 50, 215) it is produced on the surface of iron which has been subjected to great pressure, the formation of a film of this oxide on iron rails is the reason why the surfaces of the rails of railroads do not rust (Spring, *lc*) When iron is strongly heated in air a film (*hammer scale*) is produced consisting of Fe_2O_3 , mixed with, or combined with, Fe_3O_4 , the outer layer of this film contains a large quantity of Fe_2O_3 , the inner layer, which is blackish grey and magnetic, is approximately $6FeO \cdot Fe_2O_3$ (Mosander, *P* 6, 35, *cf* Berthier, *A Ch* [2] 27, 19, Beaujeu a Mène, *C R* 61, 1135, Maumené, *Bl* 16, 25, Völcker, *W A B* 66, 193, Glasson, *A* 62, 89) *SG* 5 453 (Playfair a Joule, *C S Mem* 3, 81), 5 3 at 165° (Herapath, *P M* 64, 321) *SG* of *magnetite* 5 1 to 5 18 (Kopp, Rammelsberg) According to Moissan (*A Ch* [5] 21, 223) two varieties of Fe_3O_4 exist, one having *SG* 4 86 obtained by reducing Fe_2O_3 at 500° , the other having *SG* 5 18 obtained by reducing Fe_2O_3 at a higher

temperature Berthelot (*A Ch* [5] 23, 118) describes two varieties, one with *SG* 4 86 obtained by heating $FeCO_3$ to 350° , the other with *SG* 5 5 9 obtained by highly heating the first in N. *Magnetite* crystallises in regular octahedra, isomorphous with Mn_2O_3 (Rammelsberg) *C E*. 000029 (Kopp) *S H* $24^\circ-99^\circ$ 16779 (Regnault, *A Ch* [3] 1, 129) *H F* [Fe^+O^+]=26,900, [FeO, Fe^+O^+]=8,800 (Berthelot, *A Ch* [5] 23, 118)

Preparation—1 By heating $FeCO_3$ to c 350° in a current of CO , (Berthelot, *A Ch* [5] 23 118)—2 By heating $FeCl_2 \cdot 2NH_4Cl$ in air (Hauer, *W A B* 13, 456)—3 By heating FeO in a gentle stream of HCl (Deville, *C R* 53, 199)—4 By melting ferric phosphate with 3.4 pts. Na_2SO_4 (Debray, *C R* 52, 985)—5 By melting $CaCl_2$ with ferrous sulphate in a closed crucible (Kuhlmann, *C R* 52, 1283)—6 By the action of FeF_3 on boric acid at a high temperature in absence of air (Deville a Caron, *A* 108, 56)—7 By heating $FeCl_2$ with excess of Na_2CO_3 to low redness and washing with water (Liebig a Wohler, *P* 21, 582)—8 By heating Fe in steam 9 By long continued heating Fe_2O_3 to white heat (Sidot, *C R* 69, 201)—10 By reducing Fe_2O_3 in CO at 350° for about an hour (Moissan, *A Ch* [5] 21, 223, *cf* Birnie, *R T C* 2, 273, Ackermann a Sarnstrom, *B* 16, 783)—11 By dehydrating $Fe_2O_3 \cdot xH_2O$ at as low a temperature as possible (*v Hydrates of ferrous ferric oxide*, p 57)

Properties and Reactions—A black, magnetic powder, the crystals obtained by methods 4-7 (*supra*) are black octahedra. According to Moissan (*A Ch* [5] 21, 223) and Berthelot (*A Ch* [5] 23, 118), Fe_3O_4 obtained by heating $FeCO_3$ in CO , at 350° , or by reducing Fe_2O_3 by CO at 350° , or by heating reduced Fe in H saturated with H_2O , or in CO_2 at 440° , has a lower *SG* than Fe_2O_3 , produced by reductions at higher temperatures, or by strongly heating the first variety in N, the first variety is said to be easily soluble in conc HNO_3 Aq, and to give Fe_2O_3 when heated on Pt foil, the second variety is described as almost unacted on by boiling conc HNO_3 Aq and as unchanged to Fe_2O_3 by heat. Fe_3O_4 is reduced to Fe by heating with C, or by strongly heating in H. With a little HCl Aq it gives $FeCl_2$ Aq and Fe_2O_3 , with more HCl Aq it gives a solution showing the reactions of both ferrous and ferric chloride. According to Lefort (*C R* 69, 179) Fe_2Cl_6 is obtained by cooling a solution of $Fe_2O_3 \cdot xH_2O$ in excess of conc HCl Aq and evaporating *in vacuo* over H_2SO_4 . (*v Ferrous ferric chloride*, p 56) Lefort (*lc*) also describes a ferrous ferric sulphate— $Fe_2O_3 \cdot 6SO_3 \cdot 15H_2O$ —obtained by evaporating over H_2SO_4 solutions of Fe_2O_3 in H_2SO_4 , he says that arsenates and phosphates of Fe_2O_3 also exist, the solutions of these salts are decomposed to a mixture of ferrous and ferric salts by warming to $60^\circ-70^\circ$ (for hydrates of Fe_2O_3 , *v Hydrates of ferrous-ferric oxide*, p 57)

FERRIC OXIDE (*Peroxiide, sesquioxide, or brown oxide, of iron*) Fe_2O_3 . Occurs native in large quantities widely distributed as *red hematite*, *specular iron ore*, and *martite* *SG* native 5 2 to 5 28 (Rammelsberg, Kopp), *calciné*, 5 135 (Playfair a Joule, *C S Mem* 3, 80), *ppd*, 5 959 at 165° (Herapath, *P M* 64, 321) *S.H.*

15°-98° 16695 (Regnault, *A Ch* [8] 1, 129) CE 00004 (Kopp) Crystallises in hexagonal forms, $a = 1.186537$ (Rammelsberg)

Preparation—1. By ppg a ferro salt by NH_4Aq , thoroughly washing, and strongly heating the pp—2 By strongly heating ferrous oxalate in air, Vogel (*J pr* 68, 187) says this method gives a very pure product—3 By heating ferrous carbonate in air—4 By strongly heating ferrous sulphate in air, the product seems always to contain a little basic sulphate unless the temperature is kept very high for a long time

The oxide is obtained in crystals by the following methods—5 By heating a mixture of equal parts ferrous sulphate and NaCl , and washing with water, the temperature must not be too high, else some Fe_2O_3 is produced—6 By heating Fe_2O_3 in a slow stream of HCl gas (Deville, *C R* 52, 1364), in a rapid current of HCl , FeCl_3 is produced—7 By melting Fe_2O_3 with CaCl_2 (Kuhlmann, *C R* 52, 1283)—8 By the action of FeCl_3 vapour on strongly-heated lime (Daubré, *C R* 49, 143)—9 By melting Fe_2O_3 with borax and treating the fused mass with warm dilute HClAq (Hauer, *W. A B* 13, 456)

Properties—A reddish-brown, very hard, non magnetic powder, extremely hygroscopic, slightly volatile at c 3000° (Elsner, *J pr* 99, 257) According to Malaguti a magnetic variety of Fe_2O_3 exists (*A Ch* [3] 69, 214, cf Lallemand, *A Ch* [3] 69, 233, Lawrence Smith, *B* 8, 183)

Reactions—1 Heated to a very high temperature Fe_2O_3 is partially deoxidised to Fe_3O_4 (Sidot, *C R* 69, 201)—2 Reduced by heating in hydrogen, according to Moissan (*C R* 74, 1296) Fe_2O_3 (prepared from ferrous oxalate) is reduced to Fe_3O_4 by heating to 350° for an hour in H_2 , reduced to FeO by heating to 500° for 20 minutes in H_2 , and to Fe when heated in H_2 at 700° (cf Siewert, *J* 1864 265) Wright a Luff (*C J* 83, 1) found that the temperature at which reduction of Fe_2O_3 by H begins varies from 195° to 260° according to the physical state of the Fe_2O_3 used—3 Reduced by heating in carbon monoxide, to Fe_3O_4 at 350°, to FeO at 500°, and to Fe at 700°-800° (*M, lc*, cf Gruner, *C R* 73, 28) Temperature at which reduction begins varies from 90° to 220° according to physical state of Fe_2O_3 used (*W a L, lc*)—4 Reduced by heating with carbon to Fe_3O_4 , and then to Fe which combines with part of the C (*v Iron, carbides of*, p 53) Reduction begins at 430°-450° (*W a L, lc*) According to Parry (*C N* 27, 313) reduction of Fe_2O_3 by C in a vacuum begins at above 400°, at 1200° c $\frac{2}{3}$ of the oxide is reduced.—5 Reduced to FeO by heating in a mixture of equal volumes of carbon monoxide and dioxide (Debray, *C R* 45, 1018)—6 A mixture of carbon dioxide and cyanogen (6 vols 1 vol) partially reduces Fe_2O_3 to Fe at c 600°-700° (Bell, *J* 1874 266)—7 Heated in ammonia Fe_2N_3 is produced (*v Iron, nitrides of*, p 59) 8 Chlorine forms FeCl_3 slowly at full red heat (Weber, *P* 112, 619)—9 Heated with sulphur SO_2 and FeS are produced (Brescius, *D P J* 192, 125)—10 Heated strongly in a rapid stream of hydrogen chloride FeCl_3 and H_2O are formed (Deville, *C R* 52, 1264)—11 Sulphurated hydrogen does not act on dry Fe_2O_3 ; with

moist Fe_2O_3 ($\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$) FeS , S , and H_2O are formed (Wright, *C J* 43, 156, Brescius, *D P J* 192, 125)—12 Phosphor *c chloride* produces FeCl_3 , which then combines with part of the PCl_3 , forming FeCl_2 , PCl_3 (Weber, *J pr* 76, 410)—13 Fe_2O_3 is slowly dissolved by acids, the more slowly the denser the specimen of Fe_2O_3 , most easily dissolved by 16 times its weight of a boiling mixture of 5 pts H_2SO_4 and 3 pts H_2O (Mitscherlich, *J pr* 8^o 103) After strongly heating with alkalis, alkaline carbonates, or acid sulphates, Fe_2O_3 is readily dissolved by acids—14 Fe_2O_3 readily parts with O when heated with oxidisable organic compounds, on exposure to air O is again taken up (Robin, *C R* 49, 500, Grager, *A* 111, 124) Moist Fe_2O_3 ($\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$) in presence of ordinary air serves as an oxidiser of various vegetable matters, e.g wood (Kuhlmann, *D P J* 155, 81, cf P Thénard, *C R* 49, 289)

Combinations—1 Fe_2O_3 is extremely hygroscopic, it forms several hydrates by combining with water For conditions of formation, composition, and properties *v Hydrates of ferric oxide*, p 57—2 With some more ositive metallic oxides to form ferrites (*q v* in vol II p 547)

HYPOTHETICAL FERRIC ANHYDRIDE (Fe_2O_3) This oxide has not been isolated, but a number of salts are known, which are best regarded as derived from the hypothetical acid H_2FeO_4 , of which Fe_2O_3 would be the anhydride These salts are described under the heading FERRATES (vol II p 546) In addition to the descriptions there given it is to be noted that when air is blown into hot conc NaOHAq containing c 84 p.c NaOH , a perceptible quantity of Fe is dissolved to form a colourless liquid, from which $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ slowly separates (Zirmité, *Chem Zeitung*, 12, 355), possibly the solution contains a ferrate of Na , or, according to the suggestion of Z, a perferate NaFeO_4 (?)

Iron, oxybromides of Oxybromides of Fe are said to be formed by evaporating FeBr_3Aq , and by the action of $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ on FeBr_3Aq or HBrAq (Ordway, *J pr* 76, 19, Bechamp, *A Ch* [3] 57, 296, Scheufelen, *A* 231, 177)

Iron, oxychlorides of The oxychlorides of Fe are numerous and of complex composition, they belong to the form $x\text{FeCl}_3 \cdot y\text{Fe}_2\text{O}_3 \cdot z\text{H}_2\text{O}$ They are divided into two classes, those which are soluble in water, and those which are insoluble

Soluble oxychlorides Prepared by digesting freshly pptd $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in FeCl_3Aq , also by digesting excess of $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HClAq By the former method Ordway obtained $2\text{FeCl}_3 \cdot 28\text{Fe}_2\text{O}_3$ (*J pr* 76, 19) By the second method Béchamp (*A Ch* [3] 51, 296) obtained liquids containing FeCl_3 and Fe_2O_3 in ratio 2 5, 1 3, 1 4, and 1 5 All these solutions evaporated at c 40° give residues soluble in water, solutions containing more Fe_2O_3 than the foregoing (up to $10\text{Fe}_2\text{O}_3$) give residues on evaporation which are insol in water Solutions of soluble oxychlorides are not decomposed by dilution or heating, but addition of various acids and salts causes pptn. of $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, mixed with oxychlorides, which are soluble in water From solutions of soluble oxychlorides NH_4Aq ppts $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ free from chloride, whereas the pp obtained from the insol oxychlorides contains chloride

Insoluble oxychlorides Prepared by oxidation of FeCl_2Aq , by exposure to air or by HNO_3 in presence of a little HCl (Béchamp, *l.c.*) 10 saturated FeCl_2Aq , HCl is added in less proportion than 3HCl to FeCl_2 , the solution is heated to 100° , and HNO_3Aq is gradually added, a violent reaction occurs, the nearly black liquid becomes yellow, and oxychlorides separate which are insol in water. The composition of these oxychlorides varies according to the temperature and the proportion of HCl used. Insol oxychlorides are also formed by adding alkali to FeCl_2Aq in quantity insufficient for complete pptn. These oxychlorides vary in colour from yellow to brown, they are slowly soluble in HClAq , when heated they lose H_2O and HCl .

Iron, oxyfluoride of By adding NH_4Aq to a solution of FeF_3 , a yellow salt of the composition $2\text{FeF}_3 \cdot 3\text{Fe}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$ is obtained (Deville, *Ch* [3] 49, 85).

Iron, oxysulphide of According to Rammeisberg (*P* 121, 339) the product obtained by heating Fe_2O_3 in H_2S gas to near redness is $8\text{Fe}_2\text{S}_3 \cdot \text{Fe}_2\text{O}_3$.

Iron, reduced *Ferrum reductum*. Very finely divided Fe is obtained by reducing Fe_2O_3 in a stream of pure H . Reduced iron is very readily oxidised, commercial specimens generally contain 40 p.c. or more of oxide.

Iron, phosphides of Meyer in 1780, and Bergmann somewhat later, obtained a phosphide of Fe , supposing it to be a new metal they called it *Hydrosiderium* (*Berl Ges d naturforsch Freunde* [1781] 2, 334, Bergmann's *Opusc* 3, 109). Several Fe phosphides have been described. According to Lucas (*P* 132, 225) only three exist, Fe_3P , FeP , and Fe_2P . They are non magnetic and almost infusible, unchanged by cold HClAq , slowly acted on by boiling HClAq giving $\frac{1}{2}$ of their P as phosphoric acid and $\frac{1}{4}$ as PH_3 , oxidised at ordinary temperature by HNO_3 , and *aqua regia*.

Fe_2P . By heating FeS in PH_3 gas (H Rose, *P* 6, 212, 24, 333), also by heating reduced Fe or FeCl_2 in PH_3 (Freese, *l.c.*) A blue grey powder, $\text{SG } 5.04$, loses P by heating in H or CO , probably forming FeP .

FeP . By heating FeS in PH_3 for a long time (Freese, *l.c.*), also by passing a mixture of H and P vapour over strongly heated Fe_2O_3 , and by the action of PH_3 on FeCl_2 (H Rose, *l.c.*) A black crystalline mass, not acted on by HNO_3 , or HClAq , nor by I .

Fe_3P . 7 parts dry FePO_4 with 1 part lamp black are covered with a layer of NaCl and heated to whiteness, and the fused mass is treated with HClAq , FeP remains as a grey crystalline solid, $\text{SG } 5.74$, unchanged by heating in H , CO , or CO_2 (Freese, *l.c.*)

The following phosphides have been described in addition to those mentioned, according to Freese they are not definite compounds— Fe_2P (Hvoslef, *A* 100, 99), Fe_2P_2 (Schenk, *O J* [2] 11, 826), Fe_2P_2 (Struve, *J pr* 79, 321), Fe_2P (Sidot, *O R* 74, 1425).

Iron, salts of Two series of Fe salts, obtained by replacing H of acids by Fe , are known, *ferrous* salts FeX , and *ferric* salts FeX_3 ($\text{X} = \text{Cl}$, &c., NO_2 , &c., $\frac{\text{SO}_3}{2}$, &c., $\frac{\text{PO}_4}{3}$, &c.). The ferrous

salts are the more stable, as a class ferrous salts are readily oxidised to FeX_3 . Both series contain many well marked and very definite compounds. Lefort (*C R* 69, 179) asserts the existence of a few salts, e.g. chloride, sulphate, phosphate, corresponding to Fe_2O_3 (*vs Ferrosio-ferric oxide*, p 61). Ferrous salts are usually obtained by dissolving Fe in various acids, or in the cases of the insol salts by double decomposition from FeSO_4 , they are for the most part sol in water, a few basic ferrous salts are known, but the greater number are normal salts. Many double ferrous salts, especially with the alkali sulphates, have been isolated, many ferrous salts are isomorphous with the corresponding salts of Co , Ni , Mn , Zn , and Mg . A double ferrous aluminium sulphate, $\text{FeSO}_4 \cdot \text{Al}_2\text{SO}_4 \cdot 24\text{H}_2\text{O}$, is said to exist and to be isomorphous with the alums. Ferric salts are generally prepared by dissolving $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in the different acids, many basic, and numerous double, ferric salts are known, the double salt $(\text{NH}_4)_2\text{SO}_4 \cdot \text{Fe}(\text{SO}_4)_2 \cdot 24\text{H}_2\text{O}$ belongs to the class of alums. The ferric salts are generally analogous to the persalts of Al , Cr , Co , Ni , and Mn (*cf IRON GROUP OF ELEMENTS*). The following list comprises the more important salts of Fe derived from oxyacids, for details *cf* CARBONATES, NITRATES, SULPHATES, &c. *antimonates*, *arsenates* and *ites*, *borates*, *bromates*, *carbonates*, *chlorates*, *chromates*, *hypophosphites*, *iodates*, *molybdates*, *mobates*, *nitrates*, *perchlorates*, *periodates*, *phosphates* and *ites*, *selenates* and *ites*, *silicates*, *sulphates* and *ites*, *tantalates*, *tellurates* and *ites*, *thiosulphates*, *titانات*, *tungstates*, *vanadates*.

Iron, selenides of Selenides of Fe seem to be obtained (1) by passing vapour over strongly heated Fe , (2) by heating the product obtained in (1) with Se (Berzelius), (3) by method (2) covering the mass with borax, Little (*A* 112, 211) obtained Fe_2Se_3 , thus, $\text{SG } 6.38$, (4) by ppg Fe salts by H_2Se (Reeb, *J Ph* [4] 9, 173). By heating Fe filings with Se to redness Diversa a Shimidzu (*C J* 47, 441) obtained FeSe , resembling FeS in appearance, with acids yields H_2Se .

Iron, selenocyanides of None has been isolated, Crookes (*C J* 4, 12) mentions various reactions which do not yield a definite salt.

Iron, silicide of It is doubtful whether any definite compound has been isolated. Silicides are apparently formed (1) by heating Fe with Si (Deville a Caron, *C R* 45, 163), (2) by the action of molten Fe on silicates. Hahn (*A* 129, 57) obtained a body approximately Fe_2Si by fusing 60 parts Na_2SiF_6 , 20 parts Na , 60 parts Zn , and 22 parts steel, under NaCl . Other bodies, approximately FeSi and Fe_2Si_3 , are described by Deville a Caron (*l.c.*) and Hahn (*l.c.*, *cf* Bous singault, *A Ch* [3] 16, 15).

Iron, silicofluoride of, FeSiF_6 , *vs Ferrous fluoride*, p 56.

Iron, sulphocyanides of, *vs* vol II p 350.

Iron, sulphides of Four are known, FeS , Fe_2S_3 , Fe_3S_4 , and FeS_2 , a subsulphide, Fe_2S , also probably exists. According to Gautier a Hallopeau (*C R* 108, 806) a yellow grey lustrous body, Fe_2S , is formed by heating Fe in CS_2 for several hours at 1300° – 1400° .

Iron subsulphide Fe_2S . Said by Arfwedson (*P* 1, 72) to be produced, as a greyish-black powder, by heating dry FeSO_4 in H .

Ferrous sulphide FeS (*Iron monosulphide* or *protosulphide*) Occurs sometimes in meteorites, also in combination with NiS

Formation—1 By heating FeS_2 with Fe until the mass is thoroughly molten—2 By reducing FeS_2 in H—3 By the reduction of Fe_2O_3 or ferric salts by decomposing organic matter in presence of sulphates (Chevreul, *C R* 43, 218) 4 By gently heating a mixture 1 part S with 1½ parts Fe filings moistened with water, if a considerable quantity of such a mixture is made into a paste with water and covered with earth, the mass after a time becomes red hot and evolves much steam which throws up the earth with some violence—5 By strongly heating Fe_2O_3 or a ferric salt in H_2S (Sidot, *C R* 66, 1257, cf Carnot, *Bl* [2] 32, 162)—6 By heating a mixture of Fe_2O_3 and S in H (Rose, *P* 110, 120)—7 By heating to redness a mixture of Fe_2O_3 and excess of $\text{Na}_2\text{S}_2\text{O}_3$ (Gibbs, *Am S* [2] 37, 346)

Preparation—1 A mixture of 8 parts Fe filings and 2 parts S is strongly heated in a covered crucible until the whole mass is thoroughly melted, if the temperature is not high enough some Fe remains and some Fe_2S_3 is formed—2 A white hot rod of iron is plunged into molten S, the FeS formed flows off, the operation is repeated as long as any S remains (Gahn, Rammelsberg, *B B* 1862 681)—3 By ppg a ferrous salt by an alkali sulphide, preferably NH_4 sulphide

Properties— FeS prepared in the dry way is yellow-brown, lustrous, metal-like solid, crystallising in hexagonal prisms, *SG* 4.69 Non magnetic, not changed by heating out of contact with air or in H FeS prepared in the wet way is an amorphous, greenish black powder, which on gently heating in air is partly changed to FeSO_4 , it is slightly soluble in water By ppg FeS in a very dilute solution, and then dialysing away the other products of the reaction, Wimsinger (*Bl* [2] 49, 452) obtained a very dilute solution of colloidal FeS , the solution was greenish brown, oxidised and coagulated very readily

Reactions— FeS prepared in dry way 1 Heated in hydrogen, or out of contact with air, is unchanged—2 Heated in steam evolves H and H_2S , and leaves a black magnetic mass containing Fe_2O_3 (Regnault, *A Ch* [3] 62, 379)—3 Heated strongly in air forms Fe_2O_3 and SO_2 —4 With dilute hydrochloric or sulphuric acid evolves H_2S , and forms FeCl_2 or FeSO_4 —5 Oxidised by nitric acid—6 Heated with chlorine from S_2Cl_2 and FeCl_3

FeS prepared in the wet way 7 Oxidises in air at ordinary temperature, forming $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, S, and a little basic Fe sulphate (Wagner, *D P J* 192, 131)—8 Slightly soluble in water, re-ppd by NH_4HS —9 Soluble in sulphurous acid solution, also in potassium cyanide solution (Goueron, *C R* 75, 1276)—10 Slightly soluble in solutions of alkaline sulphides—11 Very easily decomposed by acids, with evolution of H_2S

Ferroso ferric sulphide Fe_2S_3 (*Magnetic sulphide of iron*) Occurs native as *magnetic pyrites* in hexagonal crystals, *SG* 4.51 to 4.64, the composition may be expressed as $x\text{FeS} \cdot \text{Fe}_2\text{S}_3$, x is very seldom = 1, generally = 5 and 6 The first product of the action of H_2S on strongly

heated Fe_2O_3 is Fe_2S_3 , but this decomposes to FeS (Sidot, *C R* 66, 1257)

Ferric sulphide Fe_2S_3 (*Sesquisulphide of iron*) By heating a mixture of powdered FeS and S to redness, or by passing H_2S over Fe_2O_3 at 100° (Berzelius, *P* 7, 393) A greenish-yellow mass, magnetic according to Proust (*Scher J* 10, 54), non magnetic according to Berzelius (*lc*) When heated, gives Fe_2S_3 , when moist soon changes to a mixture of S and Fe_2O_3 , decomposed by dilute acids forming ferrous salts, H_2S , and $\text{H}_2\text{S} \cdot x\text{S}$

Combines with Fe_2O_3 , when heated with it. The product of the reaction of H S on Fe_2O_3 at somewhat above 100° is $\text{FeO} \cdot x\text{Fe}_2\text{S}_3$, according to Rammelsberg (*P* 121, 337) Combines with CuS to form $\text{CuS} \cdot \text{Fe}_2\text{S}_3$, also with K_2S , Na_2S , Ag_2S These compounds may be regarded as *sulphoferrites*, they belong to the form $\text{M}_2\text{Fe}_2\text{S}_3$, and are produced by fusing 1 part Fe filings with 5-6 parts S and 5-6 parts alkaline carbonate, the Ag salt is obtained by adding AgNO_3 to the K salt suspended in water (v Schneider, *P* 136, 460, Preis, *J pr* 107, 10) Fe_2S_3 is said to form a hydrate, $\text{Fe}_2\text{S}_3 \cdot 3\text{H}_2\text{O}$, a greenish black pp obtained by adding $\text{NH}_4\text{HS} \cdot \text{Aq}$ to a ferric solution containing an oxidiser such as Cl or a hypochlorite (Phipson, *C N* 30, 139)

Iron disulphide FeS_2 (*Iron pyrites*)

Occurrence—In large quantities, in regular crystals as *yellow pyrites*, and in rhombic crystals as *white pyrites*

Formation—1 By slowly heating a mixture of Fe_2O_3 , S, and NH_4Cl (Wöhler, *P* 37, 238)—2 By the action of CS_2 on Fe_2O_3 (Schlagdenhaufen, *J Ph* [3] 34, 175)—3 By heating Fe, or Fe_2O_3 , with $\text{SO}_2 \cdot \text{Aq}$ in a sealed tube to 200° (Geitner, *A* 129, 350)—4 By passing H_2S over an oxide or chloride of Fe at a temperature above 100° but below redness—5 By the action of organic matter on water containing Fe and sulphates in solution—6 Glatzel (*B* 33, 37) obtained crystals of FeS , by strongly heating FeCl_3 with P_2S_5

Preparation—1 An intimate mixture of 2 parts FeS and 1 part S, or of 1 part Fe with 1½ parts S, is heated in a retort to a temperature somewhat under red heat, and the product is treated with dilute $\text{HCl} \cdot \text{Aq}$ (Berzelius), below 100° the chief product is FeS_2 , and at red heat Fe_2S_3 is formed—2 By mixing an alkaline per sulphide solution with $\text{FeCl}_2 \cdot \text{Aq}$ at 180° or with $\text{FeSO}_4 \cdot \text{Aq}$ at 165° (Benarmont, *A Ch* [3] 30, 129)

Properties—A bulky dark yellow powder, or crystallised in small brass yellow cubes and octahedra Not magnetic The rhombic form of FeS_2 oxidises in moist air forming $\text{FeSO}_4 \cdot \text{S}$, and H_2SO_4

Reactions—1 White iron pyrites, finely-divided yellow pyrites, or FeS_2 prepared in the wet way, oxidise in air, forming chiefly FeSO_4 , and at higher temperatures SO_2 and Fe_2O_3 —2 Calcined with carbon, gives CS_2 —8 Not acted on by dilute acids, but decomposed by conc hydrochloric acid, giving H_2S and S—4 Oxidised by heating with conc nitric acid

Iron, telluride of Produced by reducing ferrous telluride in H (Berzelius)

IRON ALUMS

K_2 (or $(\text{NH}_4)_2$) $[\text{SO}_4 \cdot \text{Fe}_2(\text{SO}_4)_2 \cdot 24\text{H}_2\text{O}]$, v ALUMS, vol I. p 148, and SULPHATES. M M P. M.

IRON GROUP OF ELEMENTS The four elements, IRON, NICKEL, COBALT, and MANGANESE, are more or less closely connected. Fe, Ni, and Co occur in meteorites, some of which also contain minute quantities of Mn. The chief ores of Fe and Mn are oxides, carbonates, and sulphides, of Ni and Co sulphides and arsenides. Fe has been known and used for ages, Ni, Co, and Mn have been known from about the middle of the eighteenth century. The name *iron* is probably a form of the Sanscrit word *ayas* (= metal), the names *nickel* and *cobalt* are derived from terms used by miners in the Middle Ages to express false or spurious metals, or minerals from which no useful metals could be obtained, *manganese* is said to be a corruption from *mag-*

nesia nigra, a name long given to the mineral pyrolusite. Compounds of Fe occur in large quantities, widely distributed, compounds of Mn are not so common, nor so widely distributed, and compounds of Ni and Co occur only sparingly. Fe, Ni, Co, and Mn are obtained by reducing the oxides with charcoal at high temperatures. The metals are all hard, lustrous, fairly malleable and ductile, they crystallise in the regular system, they are more or less magnetic, they are unacted on by dry air, but oxidise slowly in moist air, they decompose steam, and react with acids to form salts. The following table presents some of the characteristic properties of the four metals —

	MANGANESE	IRON	NICKEL	COBALT
Atomic weights	55	55.9	58.6	58.8
One compound of Mn ($MnCl_2$), and two of Fe ($FeCl_2$ and $FeCl_3$) have been gasified, no Ni or Co compounds have been gasified, specific heats of the four metals have been directly determined. Molecular weights unknown				
Melting points (approx)	1800°–1900°	1600°	1500°	1500°
Spec. gravs (approx)	8	7.8	8.9	8.6

Spec. grav (approx)				
Occurrence and Preparation.	Occurs chiefly as MnO_2 . Obtained by reducing the oxides by C at a high temperature, Also by reducing the chloride or fluoride by Na.	Chiefly as Fe_2O_3 , Fe_3O_4 , and $FeCO_3$. Obtained by reducing Fe_2O_3 by C, or CO, at a high temperature, also by reducing Fe_2O_3 or Fe_3O_4 in H, and by electrolysis of $FeSO_4$ in Aq.	Chiefly as $NiAs$ and $NiAsS$. Obtained by reducing Ni_2O_3 by C at a high temperature, or by heating in H.	Chiefly as $CoAs_2$ and $CoAsS$. Obtained by reducing Co_2O_3 by heating with C or in H.
Physical properties	Greyish-white, brittle, very hard, lustrous, magnetic. Melts above M.P. of Fe.	Lustrous, greyish-white, very tenacious, crystallises in regular cubes and octahedra, magnetic. Ordinary iron, containing from 2 to 5 p.c. C, is very hard, malleable, and fairly ductile. Fe obtained by reduction of Fe_2O_3 in H below 600° is pyrophoric. By electrolysis of $FeSO_4$ in Aq a soft, amorphous, brittle mass is obtained.	Silver white, very tenacious, hard, ductile, malleable, magnetic up to c. 250°, crystallises in regular cubes and octahedra.	Steel grey, lustrous, hard, very ductile at red heat and upwards, somewhat malleable, magnetic, crystallises in regular cubes and octahedra.
Chemical properties	Oxidises easily in air, Mn obtained by reducing chloride by Na is said not to tarnish in ordinary air. Oxidised by heating in air. Decomposes steam, said to decompose	Unchanged in dry air, in moist air forms $Fe_2O_3 \cdot xH_2O$, heated in air or O, burns to Fe_2O_3 , and Fe_3O_4 . Decomposes steam, forming Fe_2O_3 and H. Dissolves in dilute acids, almost in-	Unchanged in ordinary air, heated in air or O burns to NiO or Ni_2O_3 , according to the temperature. Decomposes steam at red heat. Dissolves in dilute acids, but is unacted on by	Unchanged in ordinary air; heated in air or O burns to Co_2O_3 . Decomposes steam at red heat, decomposes NH_3 to N and H. Dissolves in dilute acids, but is unacted on by

TABLE—continued

	MANGANESE	IRON	NICKEL	COBALT
	<p>cold water slowly. Dissolves in dilute acids, hardly acted on by cold conc H_2SO_4. Combines directly with Cl and Br. No simple cyanide of Mn is known, but the acid H_2MnCy_2 and salts derived from it, and also salts of the hypothetical acid H_2MnCy_2, have been isolated. With acids forms two series of salts, MnX_2 and MnX_3, of which the manganese salts ($X = Cl, SO_4, \&c$) are the more stable. Besides the oxides corresponding to the salts (MnO and Mn_2O_3) other acidic oxides, MnO_2 and Mn_2O_7, have been isolated, the acid $HMnO_4$, and numerous salts of this acid, are known, salts of the hypothetical acid H_2MnO_4 are also numerous. Atom of Mn is divalent in the gaseous molecule $MnCl_2$.</p>	<p>sol in cold conc H_2SO_4, unacted on by cold conc HNO_3. Combines directly with Cl, Br, and I, also with C, and probably with H and N. No simple cyanide is known, but a large number of ferro and ferric cyanides, and also the acids H_2FeCy_2 and H_2FeCy_3, have been isolated. Some ammonio compounds are known. Reacts with acids to form two series of salts, FeX_2 and FeX_3, of which the ferric salts ($X = Cl, SO_4, \&c$) are the more stable. Ferrates, M_2FeO_4, are also known, but neither the corresponding acid nor anhydride has been isolated. Atom of Fe appears to be divalent and trivalent in gaseous molecules ($FeCl_2$ and $FeCl_3$), perhaps also tetravalent (Fe_2Cl_4 and Fe_2Cl_6).</p>	<p>cold conc HNO_3. Combines directly with Cl, Br, and I. Probably forms a nitride by heating NiO in NH_3, N Cy_2 and many double cyanides are known, but no acids or salts corresponding with ferro, ferri, manganese, and manganese cyanides have been isolated. Some ammonio compounds are known. With acids forms two series of salts, NiX_2 and NiX_3, of which the nickelous salts ($X = Cl, SO_4, \&c$) are much the more stable. No salts in which Ni forms part of the acidic radicle have yet been certainly isolated.</p>	<p>cold conc HNO_3. Combines directly with Cl, Br, and I, also probably with C. $CoCy_2$ is known, also the acids H_2CoCy_2 and H_2CoCy_3, and many salts derived therefrom. Very many ammonio compounds are known. With acids form two series of salts, CoX_2 and CoX_3, of which the cobaltous salts ($X = Cl, SO_4, \&c$) are much the more stable. By the action of molten KOH on CoO a salt is obtained in which Co seems to form part of the negative radicle.</p>

General formula and character of compounds—Oxides— MO, M_2O_3, M_2O_5 , also MnO_2 , MnO_3 , Mn_2O_3 , Sulphides— MS, M_2S, M_2S_3, MS_2 . Haloid compounds— MX_2 or M_2X_3 , also FeX_2 or Fe_2X_3 , $?MnCl_2$, $?MnCl_3$. Salts— MX_2 and MX_3 , $X = NO_2, \frac{SO_4}{2}, \frac{PO_4}{3}, \&c$ Salts

containing M in the acidic radicle— Ni_2MO_4 , where $M = Mn$ or Fe , also Ni_2MnO_4 ($?NaFeO_4$), also $\alpha MO yFe_2O_3$, where $M =$ decidedly positive metal. Acids— $HMnO_4$.

The oxides MO are basic. They react with acids to form salts MX_2 . MnO and FeO are readily oxidised by standing in air, FeO very rapidly. NiO and CoO , on the other hand, are obtained by heating the higher oxides in air. The oxides M_2O_3 are basic, forming salts MX_3 . In the case of Mn only a few salts corresponding to M_2O_3 are known, e.g. $Mn_2(SO_4)_3$. In the cases of Ni and Co the salts of M_2O_3 are hardly known, the oxides dissolve in cold conc acids, probably forming salts, but on warming salts of MO are obtained. Both Fe_2O_3 and Mn_2O_3 show feebly acidic properties, as they combine with some more basic oxides, e.g. CaO, BaO, ZnO .

The oxides M_2O_3 react with acids, for the most part, as compounds of MO with MO_2 . Fe_2O_3 , however, is said to produce a few corresponding salts, e.g. Fe_2Cl_4 and $Fe_2(SO_4)_3$. It is doubtful whether MnO_2 form any corresponding salts, with acids it usually evolves O , and forms managanous salts MnX_2 . It combines with several more positive oxides, e.g. CaO or Br_2O , to form compounds $\alpha M^{II}O yMnO_2$. MnO_2 and Mn_2O_3 are extremely unstable acidic oxides. The acid of Mn_2O_3 , viz. $HMnO_3$ or $H_2Mn_2O_3$, is known, and from it a large series of salts has been obtained. The acid of MnO_2 (H_2MnO_4) has not been isolated, but the manganates $M^{II}MnO_4$ are well known salts. Ferrates, M_2FeO_4 , corresponding to the manganates, are known although neither the acid H_2FeO_4 nor the anhydride FeO_3 has been isolated.

The sulphides MS are basic, but MnS shows slightly acidic properties. MnS forms a compound with the very positive K_2S ($K_2S \cdot 3MnS$), CoS , on the other hand, combines with the slightly negative As_2S_3 ($2CoS \cdot As_2S_3$). Fe_2S_3 forms compounds with Ag_2S , CuS , &c, which may be regarded as sulphoferrites.

The *haloid compounds* MX_2 or IX_3 , are generally formed by direct union of the elements, also by dissolving the oxides MO in the haloid acids HX and evaporating. Fe is the only member of the group which certainly forms haloid compounds containing more halogen than MX_2 . There are, however, indications of the existence of $MnCl_3$ and $MnCl_4$. The haloid compounds which have been gasified are $MnCl_2$, $FeCl_2$ and $FeCl_3$. There are no indications of the existence of gaseous molecules Mn_2Cl_4 , but the V D s of ferrous and ferric chlorides point to the existence of the gaseous molecules $FeCl_2$ and $FeCl_3$ at high temperatures, and Fe_2Cl_4 and Fe_3Cl_8 at lower temperatures.

The *salts* of the metals of the iron group belong to the series MX_n and $MX_n \cdot xH_2O$, where $X = NO_3, ClO_4, SO_4, CO_3, PO_4$, &c. Fe forms many salts of both series, Mn forms chiefly many ganous salts MnX_n , but a few manganic salts are known, e.g. $Mn_2(SO_4)_3$, Ni forms only nickelous salts NiX_2 . The cobaltic salts are represented by a few double salts, e.g. $Co(NO_2)_2 \cdot 3KNO_2$, but the cobaltous salts are numerous. Ferrous salts are perfectly definite, but are fairly easily oxidised to ferric. Ferric and manganic sulphates form alums, $K_2SO_4 \cdot Fe_2(SO_4)_3$ or $Mn_2(SO_4)_3 \cdot 24H_2O$. Many of the salts MX_2 are isomorphous with the corresponding salts of Cu, Zn, Mg, and Cd.

The only member of the series which forms *acidic oxides* that have been isolated is Mn (*v supra*). Permanganic acid, $HMnO_4$, has also been isolated, but no oxyacid of Fe, Ni, or Co.

The iron elements exhibit analogies with several other families of elements. Their relations with the elements of Group III, especially with Al, Ga, and In, are shown in the composition of the salts MX_3 , in the existence of alums, e.g. $K_2SO_4 \cdot M(SO_4)_3 \cdot 24H_2O$, where $M = Al, Ga, In, Fe, or Mn$, also in the existence and dissociation of the gaseous molecules Fe_2Cl_4 , Al_2Cl_6 , and Ga_2Cl_6 . The analogies shown by Ni and Co to the Al family are very slight.

The iron family is distantly connected with the halogens. This is shown in the existence of the salts $NiMO_4$, where $M = Mn$ (?), $Cr, Cl, or I$.

The relations between the iron family and the chromium family of Group VI are fairly well marked, the MX_3 salts are similar to the CrX_3 salts, MnO_2 resembles CrO_3 , in being acidic and forming salts M_2MnO_4 , analogous to and isomorphous with the chromates. Ferrates, M_2FeO_4 , are also known, although neither FeO , nor H_2FeO_4 , has been isolated. MnO_2 is not unlike CrO_3 , in some of its reactions. The sulpho ferrites, e.g. $CuFe_2S_4$, resemble the sulpho chromites, e.g. $ZnCr_2S_4$. The relations of Ni and Co to the Cr family are chiefly shown in the formulae of the nickelous, cobaltous, and chromous salts, MX_2 , in the existence of many ammonio-cobalt and ammonio-chromium compounds. The formation of the cyanogen acid $H_2M_2Cy_4$, and of salts of $H_2M_2Cy_4$, where $M = Mn, Fe, Co, or Cr$, is a point of similarity between Cr and the iron family.

The composition of the salts MX_2 is similar to that of the salts of Group II, so far as properties go these salts most resemble those of the odd series members of Group II, Mg, Zn, and Cd, the ammonio-compounds of Co also recall

the ammonio-compounds of Hg which is an odd series member of Group II.

There are some resemblances between Cu which belongs to Group I and the iron elements, thus the salts MX_2 resemble in many respects the cupric salts CuX_2 , there are many ammonio-copper compounds, numerous double cyanides of Cu exist and some of those are probably derived from a cyanogen acid $H_2Cu_2Cy_4$.

Finally some of the physical properties of the iron family resemble the properties of the two other families of Group VIII, viz Rh, Ru, Pd, and Os, Ir, Pt, this resemblance is carried out in the formulae of some of the salts, and in the existence, and in some cases the composition and properties, of numerous complex cyanides; these complex cyanides are indicated in the following table —

$H_2M_2Cy_4$, and salts.	$H_2M_2Cy_4$, and salts.
$M = Mn, Fe, Co, Os, Ru$	$M = Fe, Co, Ir$
Salts of $H_2M_2Cy_4$, (acid not isolated)	
$M = Mn, Rh$	

The acid H_2PtCy_4 and salts of this acid exist, salts of H_2PdCy_4 are known. It should be noted that Ni does not form nickelous or nickelic cyanides analogous to any of the complex cyanides formulated above, but only ordinary double cyanides.

The position of the iron family of elements in the classification based on the periodic law is somewhat peculiar (*v Table on p 204 of vol II*). Mn is placed in the even series of Group VII, the only other members of this group as yet known are the halogens Fe, Ni, and Co form a division, or family, of Group VIII, the other families of this group are (1) Rh, Ru, Pd, and (2) Os, Ir, Pt. The iron family should therefore, strictly, include only Fe, Ni, and Co, Mn has been included in this family because of its close relations to Fe, but because of its position in Group VII, Mn has also been included in the halogen family (*v HALOGEN ELEMENTS*, vol II p 664). Each of the three families which together constitute Group VIII is separated from the others by many elements, the analogies between these families cannot be very close. The iron family is preceded in order of atomic weights by a series of elements, which begins with the very positive element K and ends with the element Cr which is both metallic and non metallic, the iron family is succeeded by series 5 which begins with the undoubtedly metallic Cu and ends with the no less undoubtedly non metal Br. The iron family forms one of the turning points in the swing of properties from very positive to very negative, the next similar turning point is marked by the second family of Group VIII, Rh, Ru, Pd, and the third turning point is marked by the last family of Group VIII, Os, Ir, Pt. Recent researches show that Co and Ni are perhaps separable each into two other elements, *v NICKEL* in this volume. In connection with this article *v CHROMIUM GROUP OF ELEMENTS*, vol II p 168, *COPPER GROUP OF ELEMENTS*, vol II p 250, *EARTHS, METALS OF THE*, vol II p 424, *HALOGEN ELEMENTS*, vol II p 664 *NOBLE METALS*, in this vol. M M P M

ISAMIC ACID *v* ISATIN.ISATANE *v* ISATYDEISAMIC ACID $C_8H_5NO_3$, *is*

$C_8H_5(NH_2)COCO_2H$ *o* Amido phenyl glyoxylic acid. Formed, as potassium salt, by boiling isatin with conc KOHAq (Laurent, *A Ch* [3] 3, 371, Erdmann, *J pr* 24, 13). Obtained synthetically by reduction of an alkaline solution of *o*-nitro-phenyl-glyoxylic acid with ferrous sulphate (Claisen & Shadwell, *B* 12, 353). By decomposing the lead salt with H_2S and evaporating at atmospheric temperature *in vacuo* isamic acid may be obtained as an amorphous white powder, soluble in cold water. The acidified solution deposits, after a while, crystals of isatin, which is its anhydride, and the separation may be hastened by warming. With acetone in alkaline solution isamic acid forms (*Py* 3)-methyl quino line (*Py* 1) carboxylic acid [241°]. Its silver salt forms microscopic needles (W Pitzinger, *J pr* [2] 33, 100, Beyer, *J pr* [2] 33, 416). Acetophenone gives, in like manner, phenyl-quino line carboxylic acid.

Salts—KA' faint yellow crystals, which dissolve in conc KOHAq, forming a deep violet red solution, turned yellow on dilution with water. Its solution gives a yellow flocculent pp with lead acetate, and, when concentrated, it is also ppd by $BaCl_2$ —BaA', (at 150°) scales.—AgA' beautiful yellow prisms, sol water.

Acetyl derivative $C_8H_5(NHAc)COCO_2H$ [160°]. Obtained from acetyl-isatin by dissolving in cold dilute NaOHAq and ppg with dilute H_2SO_4 (Suida, *B* 11, 586). Needles (from alcohol). Sl sol cold water, m sol alcohol, ether, and benzene. Boiling HClAq converts it into isatin. Sodium amalgam reduces it to the acetyl derivative of *o* oxy *o* amido phenyl acetic acid $C_8H_5(NHAc)CH(OH)CO_2H$, which forms colourless needles [142°] converted by HI into oxindole.

Chloro isamic acid $C_8H_5Cl(NH_2)COCO_2H$. From chloro isatin by warming with KOHAq (Erdmann, *J pr* 19, 339, 24, 5, *A* 33, 129, Laurent, *A Ch* [3] 3, 378). Not known in the free state, since, when its salts are acidified, chloro-isatin is formed—KA' light yellow flattened needles (from alcohol), v sol water—BaA', aq pale yellow needles—BaA', 3aq brilliant deep yellow laminae—PbA', 2aq brilliant yellow gelatinous pp, which in a few minutes changes to scarlet PbA', aq—AgA' light yellow pp, sol boiling water—The cupric salt is ppd as a brownish red powder, which changes to blood red.

Di-chloro-isamic acid $C_8H_3Cl_2(NH_2)COCO_2H$. Formed by dissolving di chloro isatin in hot KOHAq. Separates on addition of HCl as a yellow pp, which, even when exposed over sulphuric acid *in vacuo* in the cold, splits up into water and di chloro isatin. It dissolves in water forming a light yellow solution, which becomes turbid at 60° and deposits di chloro isatin—KA' aq yellow laminae—BaA', 2aq golden needles—CuA', reddish brown pp changing to greenish yellow and crimson—AgA'. small yellowish needles (from hot water).

Bromo-isamic acid $C_8H_5Br(NH_2)COCO_2H$. Formed by warming bromo isatin with aqueous caustic potash (Gericke, *J pr* 95, 176, 257). The free acid splits up at once into isatin and bromo-

isatin—LA' easily soluble cauliflower like crystals—NaA' warty crystals—BaA', 3aq yellow prisms—CuA', 2aq red granular pp—PbA', 2aq yellow pp, changing to a scarlet crystalline powder—ZnA', 2aq brownish pp, changing to red granular powder—AgA' light yellow needles (from hot water).

Di-bromo-isamic acid $C_8H_3Br_2(NH_2)CO_2H$. From di bromo isatin and hot KOHAq (Erdmann, *J pr* 19, 360). The free acid is ppd by adding HCl to a conc solution of the K salt as a light yellow powder, soluble in a large quantity of water. By desiccation, even at 15° *in vacuo*, it is decomposed into di bromo isatin and water—KA' aq pale yellow needles, v sl sol water.

Ethylether EtA' [105°]. From the silver salt and EtI (Baeyer & Oekonomides, *B* 15, 2099). V sol ordinary solvents. At 110° it gives di bromo isatin.

Sulpho-isamic acid

$C_8H_5(SO_3H)(NH_2)COCO_2H$. From isatin sulphonic acid and excess of alkali (G & A Schlieper, *A* 120, 12). Only known in its salts, which are converted by mineral acids into isatin sulphonic acid—KA' aq waxy yellow prisms, v sol water—BaA', 3aq long silky lemon yellow needles, v sol boiling water, insol alcohol—PbA', 14aq yellow needles, v sol water—AgA', 14aq pale yellow needles, sl sol water.

Isomeride of isamic acid *v* m AMIDO-PHENYL GLYOXYLIC ACID

p Methyl isamic acid *Acetyl derivative* $C_8H_5(CH_3)(NHAc)COCO_2H$ [172°]. Small white needles, soluble in alcohol and hot water, very sparingly in ether, benzene, ligroin, and CS₂. Formed by the action of cold aqueous alkalis upon acetyl *p* methyl pseudo isatin.

Ethyl ether of the acetyl derivative $C_8H_5(CH_3)(NHAc)COCO_2Et$ [79°]. White glistening plates, insol water. Formed by boiling acetyl *p* methyl pseudo isatin with dilute alcohol (Duisberg, *B* 18, 198).

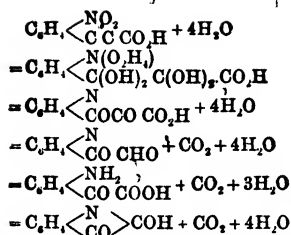

Amide of the acetyl derivative

$C_8H_5(CH_3)(NHAc)COCONH_2$ [141°]. Formed by the action of alcoholic NH_3 on the acetyl derivative of methyl ψ isatin (Panaotović, *J pr* [2] 33, 72). Trimetric prisms (from alcohol), insol water.

ISATILIM *v* ISATINISATIMIDE *v* ISATINISATIN $C_8H_5NO_2$, *is* $C_8H_5\langle\begin{smallmatrix} CO \\ N \end{smallmatrix}\rangle COH$

(stable form) or $C_8H_5\langle\begin{smallmatrix} CO \\ NH \end{smallmatrix}\rangle CO$ (transition form) or pseudo isatin. *Anhydride of isamic acid* *o*-Amido phenyl glyoxylic lactum [201°].

Formation—1 Discovered simultaneously by Laurent (*A Ch* [3] 3, 371) and by Erdmann (*J pr* 24, 11) as a product of the oxidation of indigo by nitric acid (L) or chromic acid (E)—2 By oxidising amido oxindole with $FeCl_3$, nitrous acid, or $CuCl_2$ (Baeyer, *B* 11, 1228). The oxindole may be obtained from phenyl acetic acid by nitration and reduction (Baeyer, *B* 11, 583), and converted successively into nitroso oxindole and amido oxindole—3 Prepared by boiling *o* nitro phenyl propionic acid with alkalis (Baeyer, *B* 13, 2259). The reaction possibly takes place as follows—

(Michael, *J pr* [2] 25, 255) —4 Together with $\text{N}_2(\text{C}_6\text{H}_7\text{N}, \text{CO}_2\text{H})_2$ by dissolving isatogenic ether in aqueous Na_2CO_3 (Baeyer, *B* 15, 55) —5 From isatogenic acid by dissolving in H_2SO_4 and adding water (Baeyer *B* 14, 1742) —6 By oxidising carbostyryl with alkaline KMnO_4 (Friedlander & Ostermaier, *B* 14, 1921) —7 By boiling nitroso (γ) oxy carbostyryl with conc HClAq (Baeyer & Homolka, *B* 16, 2217) —8 By heating anthroxanic acid with FeSO_4 and dilute ammonia (Schillinger & Wleügel, *B* 16, 2224)

Preparation —1 Finely powdered indigo (50g of 65 p c) is made into a thin paste with boiling water, and a dilute solution of CrO_3 (30 g) is added. The liquid is boiled till it begins to froth strongly, and is then filtered hot, when isatin separates on cooling. The yield is moderate (9 g) (Sommaruga, *A* 190, 369) —2 A mixture of indigo (100 pts), boiling water (300 pts), and nitric acid (70 pts of *S G* 135) is boiled for two minutes, diluted with boiling water (2000 pts), boiled for five minutes more and filtered. The isatin separates on cooling. It may be purified by dissolving in aqueous KOH , adding HCl as long as it forms a black or brown pp, filtering adding more HCl to the clear yellow filtrate, and washing the red pp of isatin (Forrer, *B* 17, 976, Hofmann, *A* 53, 11)

Properties —Yellowish-red monoclinic prisms, $a, b, c = 42.5 : 1.503, \beta = 85^\circ 18'$ (Bodewig, *Z K* 4, 65). Has no odour, but a bitter taste. Sl sol cold, m sol boiling, water, forming a reddish yellow solution. V c sol alcohol, sl sol ether. The alcoholic solution imparts an unpleasant odour to the skin.

Reactions —1 It is not attacked by dilute nitric acid, but a stronger acid forms nitro-oxy benzoic acid, while conc HNO_3 forms oxalic acid —2 Nitrous acid, acting upon isatin suspended in water, forms nitro-oxy-benzoic acid (Hofmann, *A* 115, 280), while, in presence of alcohol, nitrous acid forms benzoic acid (Baeyer & Knop, *A* 140, 4) —3 Chromic acid in presence of acetic acid forms isatoic acid

the other hand, acetyl isatin $\text{C}_6\text{H}_7\text{N} \begin{array}{l} \text{CO} \\ \text{N} \end{array} \text{---} \text{NAC} \text{---} \text{CO}$, being a derivative of pseudo isatin, yields acetyl-o-amido benzoic acid $\text{C}_6\text{H}_7(\text{NHAc})\text{CO}_2\text{H}$ on similar treatment (E v. Meyer & J Bellmann, *J pr* [2] 33, 30) —4 Chlorine and bromine form products of substitution —5 Cold aqueous caustic potash forms a red solution, which on boiling immediately becomes yellow, and then contains potassium isatate. If the solution be concentrated by distillation, decomposition suddenly takes place, aniline and hydrogen being

given off —6 Aqueous ammonia forms isamic acid. Alcoholic NH_3 gives a variety of products, called by Laurent imesatin, imasatin, amisatin, isatimide, and isatilum. By heating isatin with alcoholic NH_3 in sealed tubes Sommaruga (*A* 190, 371) obtained di-imido isatin, oxy-di-imido isatin, and deoxy imido isatin —7 Isatin combines with alkaline bisulphites —8 SO_2 has no action —9 H_2S gives di-thio isatide —10 Soda amalgam reduces it to isatide $\text{C}_6\text{H}_7\text{N}_2\text{O}$, and dioxindole $\text{C}_6\text{H}_7\text{NO}_2$ —11 Ammonium sulphide reduces it to isatide —12 Zinc and dilute H_2SO_4 form isatide —13 Zinc-dust and a little dilute HCl form isatide and dioxindole (Baeyer, *B* 12, 1309) —14 Zinc-dust added to a cold solution of isatin in HOAc forms a colourless solution (? of isatin hydride) which becomes coloured again on exposure to the air, isatin being reproduced —15 Aqueous HI (*S G* 14) at 100° forms isatide. At 140° it forms a dark-green insoluble mass, whence boiling alcohol leaves a dark grey residue, isatochlorin ($\text{C}_{12}\text{H}_{11}\text{N}_2\text{O}_2$), whilst the alcoholic solution, mixed with water, gives a pp, whence ether extracts red isatopurpurin ($\text{C}_{12}\text{H}_{11}\text{N}_2\text{O}_2$), while white isatone ($\text{C}_{12}\text{H}_{11}\text{N}_2\text{O}_2$) remains undissolved (Schutzenberger, *Bl* [2] 4, 170) —16 PCl_5 forms 'isatin chloride' (Baeyer, *B* 12, 456) —17 Hydroxylamine forms nitroso oxindole or isatoxim —18 Alcoholic KCl has no action —19 A solution of isatin, warmed with phenyl hydrazine, forms a pp of the phenyl hydrazide —20 In presence of H_2SO_4 or ZnCl_2 isatin forms condensation products, with (2 mols of) toluene, phenol, di-methyl aniline, thiophene, &c, by elimination of water (1 mol). Thus, phenol and H_2SO_4 give di-oxy-di-phenyl oxindole

$\text{C}_6\text{H}_7\text{N} \begin{array}{l} \text{C(C}_6\text{H}_5\text{OH)}_2 \\ \text{NHCO} \end{array}$, toluene gives di-tolyl-oxindole, while di-methyl aniline gives tetramethyl di-amido di-phenyl oxindole [234°] (Baeyer, *B* 18, 2642) —21 When heated with phenyl cyanate, for three hours at 130° , it forms the anilide of isatin-o-carboxylic acid, which crystallises from alcohol in needles [180° - 185°] (Gumpert, *J pr* [2] 31, 120, 32, 283) —22 Phenyl mercaptan, added to a hot alcoholic solution of isatin, forms silky needles of a compound ($\text{C}_6\text{H}_7\text{NO}_2$)($\text{C}_6\text{H}_5\text{SH}$), insol water, but decomposed by hot benzene into its components (Baumann, *B* 18, 890) —23 By boiling with *m*-amido-benzoic acid and alcohol there is formed an acid which is termed isat-amido-benzoic acid $\text{C}_6\text{H}_7\text{N} \begin{array}{l} \text{CNC}_6\text{H}_4\text{CO}_2\text{H} \\ \text{NH} \end{array} \text{---} \text{CO}$ [253°] *m*-Amido-benzamide gives, in like manner, the corresponding amide [c 280°] (Schiff, *A* 218, 192) —24 Heating with tolylene diamine forms $\text{C}_{12}\text{H}_{11}\text{N}_2$ [290°], which is probably a quinoxaline (Hinsberg, *A* 237, 344)

Metallic derivatives — $\text{C}_6\text{H}_7\text{AgNO}_2$ obtained by mixing isatin with water at 0° , adding KOH (1 mol) followed immediately by AgNO_3 (1 mol) (Baeyer & Oeconomidis, *B* 15, 2095) Red pp — $\text{C}_6\text{H}_7\text{AgNO}_2\text{NH}_3$ Formed in presence of ammonia (L) — $\text{Cu}(\text{C}_6\text{H}_7\text{NO}_2\text{NH}_3)_2$ From cupric acetate and an ammoniacal solution of isatin (Laurent) Brown pp —Potassium isatin is present in the violet red solution obtained by dissolving isatin in conc KOHaq

Indophenine reaction —A solution of isatin

in conc H_2SO_4 , shaken with benzene containing thiophene, is coloured blue, through formation of indophenine (*q v*). A similar reaction is given by most derivatives of thiophene

Combinations with bisulphites $\text{C}_6\text{H}_4\text{NO}_2\text{KHSO}_3 \cdot 2\text{aq}$ Formed by boiling isatin with aqueous KHSO_3 , or by saturating a solution of potassium isatate with SO_2 (Laurent) Large, pale yellow tables, v e sol water and boiling alcohol, sl sol cold alcohol Gives with lead acetate a pp of isatin and lead sulphite — $\text{C}_6\text{H}_4\text{NO}_2(\text{NH}_4)\text{HSO}_3$, pale yellow tables, sl sol cold water — $\text{C}_6\text{H}_4\text{NO}_2(\text{NH}_4\text{C}_2\text{H}_5)\text{HSO}_3$ (Schiff, *A*, 144, 49) — $\text{C}_6\text{H}_4\text{NO}_2(\text{NH}_4\text{Ph})\text{HSO}_3$ Crystals, v. sol water (S)

Acetyl- ψ -isatin $\text{C}_6\text{H}_3\text{N}(\text{CO})_2\text{CO}$ [141°]

Prepared by heating isatin (1 pt) with Ac O (2 pts) for 4 hours (Suida, *B* 11, 584) Yellow needles (from benzene) V sol benzene and alcohol, sl sol cold water Resolved into isatin and acetic acid by boiling with water, or, more readily with HClAq Cold NaOHAq dissolves it, forming $\text{C}_6\text{H}_3\text{N}(\text{NHAc})\text{CO CO}_2\text{Na}$ and, on warming, isatic acid Chromic acid in HOAc oxidises it to $\text{NHAc C}_6\text{H}_3\text{CO}_2\text{H}$

Benzoyl- ψ -isatin $\text{C}_6\text{H}_3\text{N}(\text{CO})_2\text{CO}$

From isatin and BzCl (Schwartz, *C R* 56, 1050)

Oxim $\text{C}_6\text{H}_3\text{N}_2\text{O}_2$ *re* $\text{C}_6\text{H}_3\text{N}(\text{C}(\text{NOH}))_2$ Isat

oxim Nitroso oxindole [c 202°] Formed by passing nitrous acid into a l p c aqueous solution of oxindole (Baeyer & Knop, *A* 140, 34) Formed also by boiling diazo nitroso oxindole chloride with alcohol and HCl (Gabriel & R Meyer, *B* 14, 2332) Obtained by treating isatin with hydroxylamine (Gabriel, *B* 16, 518, Baeyer & Comstock, *B* 16, 1706) Very slender golden needles Decomposed by fusion V sl sol water, sl sol alcohol Dissolves in KOHaq , forming a dark reddish brown solution Not decomposed by boiling aqueous KOH — $\text{C}_6\text{H}_3\text{AgN}_2\text{O}_2$ orange pp, got by adding dilute NH_3 to an alcoholic solution of isatin and AgNO_3 Dries up to a brick red powder

Mono-ethyl-ether of the oxim

$\text{C}_6\text{H}_3\text{N}(\text{C}(\text{NOEt}))_2\text{C}(\text{OH})$ *Isato-ethyl oxim* [188°] Fine yellow needles, soluble in caustic alkalis, formed by the action of ethyl iodide on the silver salt of isatoxim By successive treatment with zinc-dust and HOAc and with FeCl_3 it is converted into isatin

Di-ethyl-ether of the oxim

$\text{C}_6\text{H}_3\text{N}(\text{C}(\text{NOEt}))_2\text{C}(\text{OEt})$ *Ethyl-isato-ethyl-oxim* Crystalline solid, formed by the action of ethyl iodide on the silver salt of the mono-ethyl-ether (Baeyer & Comstock, *B* 16, 1706)

Oxim of ψ -isatin $\text{C}_6\text{H}_3\text{N}(\text{CO})_2\text{C}(\text{NOH})$

Isomytroso- ψ indoxyl Formed by the action of nitrous acid on ethyl indoxyllic acid

$\text{C}_6\text{H}_3\text{N}(\text{C}(\text{OEt}))_2\text{C}(\text{CO}_2\text{H})$ Flat yellow needles Decomposes at about 200° Sol alkalis and reppd by CO_2 With phenol and H_2SO_4 it does not give Liebermann's reaction Reduction with zinc-dust followed by oxidation with Fe_2Cl_3 yields isatin.

Ethyl ether of the oxim of ψ isatin

$\text{C}_6\text{H}_3\text{N}(\text{CO})_2\text{C}(\text{NOEt})$ From ψ isatoxim, KOH , and EtI yellow plates, dissolves in sodium ethylate with a blue colour, reduction with zinc dust followed by oxidation with Fe_2Cl_3 yields isatin Forms a violet solution when warmed with aqueous NaOH

Di-ethyl-derivative of the oxim of

ψ -isatin $\text{C}_6\text{H}_3\text{N}(\text{CO})_2\text{C}(\text{NOEt})_2$ [99°], yellow needles, sublimable, easily soluble in alcohol and ether, sparingly in hot water, insol alkalis On reduction with zinc dust and oxidation with Fe_2Cl_3 it yields ethyl-pseudo isatin. (Baeyer, *B* 15, 782, 16, 2191)

Phenyl hydrazide $\text{C}_{11}\text{H}_7\text{N}_3\text{O}$ [211°]

Fine yellowish red needles Formed as a yellow crystalline pp by boiling a solution of isatin in 1,000 pts of water with phenyl hydrazine hydrochloride (*q v*), the pp is quite distinct with a solution of 1 in 20,000 (E Fischer, *B* 17, 577)

Chloride $\text{C}_6\text{H}_3\text{ClNO}$ *re* $\text{C}_6\text{H}_3\text{N}(\text{CO})_2\text{CCl}$

[c 180°] Formed by warming isatin (5 g) with PCl_5 (7 g) and benzene (9 g) (Baeyer, *B* 11, 1296, 12, 456) Brown needles Decomposed on fusion V sol ether, forming a blue solution Decomposed by moist air Potash converts it into isatin HI gives indigo, zinc dust and HOAc do the same

Chloro-isatin $\text{C}_6\text{H}_3\text{ClNO}_2$ [243°] S 1 at 0°, c 5 at 100° Obtained by passing chlorine in sunlight into boiling water containing isatin in suspension The mono and di chloroisatin are separated by recrystallisation from alcohol, in which the former is much less soluble (Hofmann, *A* 53, 12, Laurent, *A Ch* [3] 3, 462, Erdmann, *A* 33, 129, Dorsch, *J pr* [2] 33, 49) Orange prisms (from alcohol) V sl sol water and alcohol Its solution imparts an unpleasant odour to the skin Decomposed on fusion Hot KOHaq forms potassium chloro isatate Distillation with NH_3 gives *p* chloro aniline An ammoniacal solution of AgNO_3 added to an alcoholic solution of chloro isatin ppts $\text{C}_6\text{H}_3\text{ClAgNO}_2\text{NH}_3$

Di chloro isatin $\text{C}_6\text{H}_2\text{Cl}_2\text{NO}_2$ [186°] Obtained from the alcoholic mother liquors that have yielded chloro isatin Small, reddish yellow needles or short laminae (from alcohol) M sol alcohol When thrown upon solid potash, moistened with alcohol, a red solution is formed which solidifies to a violet black magma of $\text{C}_6\text{H}_2\text{KCl}_2\text{NO}_2$, the solution of which gives a pp with AgNO_3 Hot aqueous KOH forms potassium di chloro isatate Distillation with KOH forms di chloro aniline Chlorine does not act on its aqueous solution, but with its alcoholic solution it forms tetra chloro quinone and other bodies KHSO_3 forms light yellow needles of $\text{C}_6\text{H}_2\text{Cl}_2\text{NO}_2\text{KHSO}_3$, sl sol boiling water Di chloro isatin (10 g) oxidised by CrO_3 (15 g) in glacial acetic acid (60 g) as described under *Bromo isatin* forms di chloro isatoxo acid (*q v*)

Bromo isatin $\text{C}_6\text{H}_3\text{BrNO}_2$ *re*

$\text{CBr CH}_2\text{C}(\text{CO})_2\text{C}(\text{OH})$ [255°] Formed, to gether with di bromo isatin, by the action of bromine and water on isatin (Erdmann, *J. pr.*

19, 558, Hofmann, *A* 53, 40) The product is exhausted with boiling water and the crystals that separate on cooling are recrystallised from alcohol whence bromo-isatin crystallises first. Orange prisms. Aqueous KOH converts it, even in the cold, into potassium bromo-isatate. Distillation with KOH yields *p* bromo aniline. When mixed with alcoholic ammonium sulphide and exposed to the air it yields bromo-indigo. Bromo isatin (10 g) is oxidised by a mixture of glacial acetic acid (90 g) and CrO_3 (15 g) to bromo-isatoic acid. The mixture must first be kept ice-cold but after 12 hours it may be slowly raised to 10° . The product, when cold, is poured into cold dilute H_2SO_4 and the yellow sandy powder crystallised from a mixture of alcohol and acetone (Dorsch, *J pr* [2] 33, 45).

cetyl derivative $\text{C}_{18}\text{H}_{15}\text{BrAcNO}_2$. [172°] Formed by boiling bromo isatin (5 pts) with Ac_2O (8 pts) (Baeyer & Oeconomidis, *B* 15, 2096). Long straw-yellow prisms (from benzene).

Chloride $\text{C}_8\text{H}_5\text{BrClNO}$. Formed by treating bromo isatin with PCl_5 (Baeyer, *B* 12, 1315). Reddish brown needles, sol hot benzene and ether. HI gives bromo-indigo.

Oxim $\text{C}_8\text{H}_5\text{BrNO}(\text{NOH})$. From isatoxim and bromine water in the cold (Baeyer & Knop, *A* 140, 35). Crystals, sl sol wat r.

[250°] Formed as above or by digesting bromo isatin or isatin with bromine in sunshine. Formed also by heating bromo isatin (1 mol) with bromine (2 mols) in HOAc for 20 hours (Baeyer & Oeconomidis, *B* 15, 2098). Orange prisms (from alcohol). Gives di bromo aniline when distilled with KOH— $\text{C}_8\text{H}_5\text{Br KNO}_2$, bluish violet scales, sl sol water. Very stable but converted into di bromo isatate by warming with KOH aq — AgA' brownish violet powder— $\text{C}_8\text{H}_5\text{Br}_2\text{NO}_2\text{KHSO}_4$, yellow solid, v sl sol water.

Oxim $\text{C}_8\text{H}_5\text{Br}_2\text{O}_2\text{N}$, or

Formed by the action of hydroxylamine on di bromo isatin (Baeyer & Comstock, *B* 16, 1708). Yellow pointed needles. Carbonises without melting at about 255° . Sol caustic alkalis but precipitated by CO_2 .

Mono-ethyl-ether of the oxim

$\text{C}_8\text{H}_5\text{Br}_2 \begin{array}{c} \diagup \text{C}(\text{NOEt}) \diagdown \\ \text{N} \end{array} \begin{array}{c} \diagup \\ \diagdown \end{array} \text{C}(\text{OH})$ *Di-bromo isato-ethyl oxim*. [252°] Yellow needles, formed by the action of ethyl iodide on the silver salt of di bromo isatoxim.

Di-ethyl ether of the oxim

$\text{C}_8\text{H}_5\text{Br}_2 \begin{array}{c} \diagup \text{C}(\text{NEt}) \diagdown \\ \text{N} \end{array} \begin{array}{c} \diagup \\ \diagdown \end{array} \text{C}(\text{OEt})$ *Di-bromo isato-ethyl oxim* [116°] Long yellow, silky needles, formed by the action of ethyl iodide on the silver salt of the mono ethyl ether.

Tri bromo isatin Oxim

$\text{C}_8\text{H}_5\text{Br}_3 \begin{array}{c} \diagup \text{C}(\text{NOH}) \diagdown \\ \text{N} \end{array} \begin{array}{c} \diagup \\ \diagdown \end{array} \text{C}(\text{OH})$ [162°] From the oxim of isatin and bromine in excess (*B* & *K*). Dirty violet needles (from alcohol). Insol

water, v sol boiling alcohol. At 190° it sublimes as red needles.

Nitro isatin $\text{C}_8\text{H}_5\text{NO}_4(\text{NO}_2)$ [226°–230°] Prepared by nitration of isatin dissolved in H_2SO_4 , by addition of powdered KNO_3 (Baeyer, *B* 12, 1312). Sparingly soluble in water, more easily in alcohol.

Bromo nitro isatin

$\text{C}_8\text{H}_5(\text{NO}_2)\text{Br} \begin{array}{c} \diagup \text{CO} \diagdown \\ \text{N} \end{array} \begin{array}{c} \diagup \\ \diagdown \end{array} \text{COH}$ [237°] From bromo-isatin, KNO_3 and H_2SO_4 (Dorsch). Clumps of orange crystals (from alcohol). Sol acetone, glacial acetic acid and alcohol, sl sol benzene and chloroform, v sl sol water and ether. Forms a dark red solution in NaOH aq , whence an orange powder presently separates.

ALKYL DERIVATIVES

Alkyl derivatives of isatin are either derived from the stable form $\text{C}_8\text{H}_5 \begin{array}{c} \diagup \text{CO} \diagdown \\ \text{N} \end{array} \begin{array}{c} \diagup \\ \diagdown \end{array} \text{COH}$

or from the transition form $\text{C}_8\text{H}_5 \begin{array}{c} \diagup \text{CO} \diagdown \\ \text{NH} \end{array} \text{CO}$ (pseudo isatin). Alkyl iodides acting on silver-isatin form alkyl derivatives of stable isatin $\text{C}_8\text{H}_5 \begin{array}{c} \diagup \text{CO} \diagdown \\ \text{N} \end{array} \begin{array}{c} \diagup \\ \diagdown \end{array} \text{COR}$

Alkyl derivatives of pseudo-isatin

$\text{C}_8\text{H}_5 \begin{array}{c} \diagup \text{CO} \diagdown \\ \text{NR} \end{array} \text{CO}$ are formed by the action of an alkaline solution of bromine or chlorine followed by alcoholic NaOH on the methyl-, ethyl-, phenyl-, &c indole carboxylic acids which are obtained by the action of HCl on phenyl methylhydrazine pyruvic acid, phenyl-ethyl hydrazine pyruvic acid, &c (Fischer & Hess, *B* 17, 559).

Methyl derivative of isatin $\text{C}_8\text{H}_5\text{O}_2\text{N}(\text{CH}_3)$

$\text{C}_8\text{H}_5 \begin{array}{c} \diagup \text{CO} \diagdown \\ \text{N} \end{array} \begin{array}{c} \diagup \\ \diagdown \end{array} \text{COMe}$ [102°] Formed by the action of methyl iodide on the silver compound of isatin (Baeyer & Oeconomidis, *B* 15, 2093). Red trimetric prisms. Sol ether, acetone, benzene, and CS_2 , less easily in alcohol, v sl sol. ligroin. It changes on keeping into methyl isatoid. Slowly dissolves in dilute KOH aq , forming a solution from which acids ppt isatin. Its solution in alcoholic ammonium sulphide forms indigo when exposed to the air.

Methyl-isatoid $\text{C}_8\text{H}_5\text{N}_2\text{O}_2$ (?) [219°] Formed by spontaneous change by keeping methyl isatin (Baeyer & Oeconomidis, *B* 15, 2094). Small yellow needles, sparingly soluble in all solvents. Dissolves in dilute NaOH on boiling, and on adding acid isatin is precipitated.

Methyl derivative of bromo-isatin

$\text{C}_8\text{H}_5\text{BrO NMe}$ [147°] Formed by the action of MeI on the silver compound of bromo-isatin (Baeyer & Oeconomidis, *B* 15, 2095). Red needles.

Bromo-methyl-isatoid [231°] Formed by spontaneous change of methyl bromo-isatin by keeping (*B* & *O*).

Methyl-pseudo-isatin $\text{C}_8\text{H}_5\text{NO}_2$, i.e.

$\text{C}_8\text{H}_5 \begin{array}{c} \diagup \text{CO} \diagdown \\ \text{NMe} \end{array} \begin{array}{c} \diagup \\ \diagdown \end{array} \text{CO}$ [134°] Red needles.

Formation—1 By the action of a cold alkaline solution of bromine or chlorine followed by hot alcoholic NaOH on methyl indole-carboxylic acid [212°], which is obtained by heating phenyl methyl hydrazine pyruvic acid with HCl (Fischer & Hess, *B* 17, 563)—2 By boiling di-

bromo-methyl oxindole with water (Colman, *C J* 55, 5, *A* 248, 118)

Reactions — Dissolves in alkalis with a yellow colour. With H_2SO_4 and benzene containing thiophene it gives the indophenine reaction. Gives a crystalline compound with phenyl-hydrazine. Yields the same product on oxidation in alkaline solutions as in acid solution, viz methyl-di-oxindole.

From methyl-pseudo isatin and hydroxylamine sulphate in hot aqueous solution (Colman, *C J* 55, 6). Tufts of small pale yellow needles, m sol. hot water, sl sol. cold water, v sol. alcohol, acetone, ether, and benzene.

[146°] Formed by the action of phenyl-hydrazine hydrochloride and NaOAc on an aqueous solution of methyl-ψ isatin. A less pure product is produced by the action of phenyl-hydrazine hydrochloride on dibromomethyl-oxindole (Colman). Fascicular group of small yellow needles, insol water and petroleum ether, sl sol. ether, v sol. hot alcohol or benzene.

p-Methyl-isatin $C_6H_4Me \cdot NO_2$ *see*

Tolysatin Anhydride of amido tolyl-glyoxylic acid [184°] (P), [187°] (M)

Formation — From *p* toluidine and di chloroacetic acid by digestion in alcoholic solution, the resulting *p* toluidine (*p*-tolyl methyl imesatin)

HCl, and the crude product purified by boiling with aqueous KOH, ppg with HCl, and crystallising from alcohol and afterwards from water (P J Meyer, *B* 16, 2261, Fr Baeyer & Co, *B* Ref. 17, 867, Panacotovic, *J pr* [2] 33, 57)

Properties — Red crystals or glistening red plates. Sol. hot water and alcohol, sl sol. cold water, v sol. hot HCl aq. Dissolves in cold alkalis with a deep-violet colour, and on heating or standing it then takes up water, becoming yellow and forming methyl isatinic acid. Dissolves in conc. H_2SO_4 with a red colour. Gives the indophenine reaction. CrO_3 in acetic acid forms methyl isatinic acid. Boiling with Ac_2O for three hours forms the acetyl derivative of methyl-ψ isatin.

Acetyl derivative of methyl-ψ

isatin $C_6H_4Me \cdot \langle \begin{smallmatrix} CO \\ NAc \end{smallmatrix} \rangle CO$ [172°] Formed by boiling *p*-methyl-ψ isatin with Ac_2O for 8 hours (Panacotovic, *J pr* [2] 33, 71). Formed also by the action of HCl upon the acetyl derivative of *p*-methyl-ψ isatin *p* toluidine (Duisberg, *B* 18, 197). Lemon-yellow needles (from benzene), sol. chloroform and benzene, sl sol. water, alcohol, ether, ligroin, and CS_2 . Converted by cold dilute alkalis into acetyl-*p*-methyl-isatinic acid. Alcoholic NH_3 converts it into the amide of acetyl-*p*-methyl-isatinic acid $C_6H_4Me(NHAc)COCONH_2$, which crystallises from alcohol in trimetric columns [141°]. CrO_3 ,

in $HOAc$ oxidises it to methyl isatinic acid, which crystallises from boiling alcohol in trimetric plates and, when heated, decomposes at 245° with great increase in bulk, finally melting at 300°.

methyl oxindole [226°] Formed by the action of hydroxylamine (base) on *p* methyl isatin (P J Meyer, *B* 16, 2268). Long yellow prisms, sol. alcohol and NaOH, sl sol. water.

Phenyl hydrazide of methyl isatin

$C_6H_4Me \cdot \langle \begin{smallmatrix} C(N \cdot HPh) \\ N \end{smallmatrix} \rangle COH$ From *p* methyl isatin and phenyl hydrazine (P). Golden needles (from chloroform). Nearly insol water, sol. alcohol. May be sublimed at 240°, but melts above 300° with evolution of gas.

Di phenyl-hydrazide of methyl ψ

Formed by warming the acetyl derivative of methyl-ψ isatin with phenyl-hydrazine (P). Yellow trimetric columns (from alcohol) decomposed by fusion. Nearly insol water, sol. chloroform.

Imide $C_6H_4N_2O$ or $C_6H_4N_2O_2$ *p* Methyl imesatin. Formed by heating *p* methyl isatin *p* toluidine with alcoholic NH_3 at 100° (P J Meyer, *B* 16, 2264). Nearly colourless fine silky needles. V sl sol. hot alcohol and hot water. Insol. cold alcohol and water. Is not reconverted into *p* methyl isatin by acids or alkalis.

Phenyl imide $C_6H_4N_2O_2$ *see*

anilide Phenyl-methyl imesatin [240°] Formed by heating *p* methyl isatin with an absolute alcoholic solution of aniline (Meyer, *B* 16, 2267). Thick yellowish red tables or prisms. Sol. hot alcohol, sl sol. cold alcohol and water. Heated with acids or caustic alkalis it is resolved into its constituents.

o Tolyl imide $C_6H_4N_2O_2$ *see*

methyl-isatin *o*-Tolyl *p*-methyl imesatin [191°] Red prismatic crystals. Formed by heating *p*-methyl isatin with an absolute alcoholic solution of *o* toluidine. By HCl or hot NaOH it is resolved into its constituents (Meyer, *B* 16, 2268).

p-Tolyl imide $C_6H_4N_2O_2$ *see*

methyl isatin *p* Tolyl *p*-methyl imesatin [259°] Formed by heating di chloroacetic acid (1 mol) with *p* toluidine (4 mols) at 100°C, either alone or in aqueous or alcoholic solution, the yield is 70 p.c. *p* Tolyl amido *p*

is first formed and then undergoes oxidation by absorption of oxygen from the air. Formed also by heating di chloroacetamide (1 mol) with *p* toluidine (8 mols), and by heating *p* methyl isatin with an absolute alcoholic solution of *p*-toluidine (Meyer, *B* 16, 2261). Glistening yellow needles or plates. Sol. ether and hot alcohol, sparingly sol. cold alcohol, insol water. By cold

HCl it is resolved into *p* toluidine and *p* methylisatin. Hot HCl or hot NaOH gives *p* methylisatinic acid—Sodium salt crystallises in red prisms, decomposed by water.

Acetyl derivative

$C_6H_5Me \begin{smallmatrix} \text{NaO} \\ > \text{CO} \\ \text{C}=\text{N}(\text{C}_6\text{H}_5) \end{smallmatrix}$ [122°] Glistening red needles, insol water. By HCl it is split up into *p* toluidine and the acetyl derivative of *p*-methyl pseudo isatin (Duisberg, *B* 18, 190).

Bromo *p* toluidide $C_6H_4BrN_2O$ [210°] Red needles or prism. By heating with acids or alkalis it is split up into its constituents (P J Meyer, *B* 16, 2267).

o Di methyl ψ -isatin $C_6H_4Me \begin{smallmatrix} \text{CO} \\ < \text{NMe} > \end{smallmatrix} \text{CO}$

Methyl ψ -o tolsatin [157°] Formed by adding pyruvic acid to a solution of methyl-*o* tolylhydrazine in dilute HCl, and warming the resulting oil with a large quantity of phosphoric acid (S G 117). The resulting di methyl indole carboxylic acid is then warmed with NaOCl in slightly alkaline solution, when a product [152°] is obtained, which when warmed with water yields the di methyl isatin (Hegel, *A* 232, 221). Brick red needles (from water).

***p* Di methyl ψ isatin** $C_6H_4Me \begin{smallmatrix} \text{CO} \\ < \text{NMe} > \end{smallmatrix} \text{CO}$ [148°] Formed in like manner from methyl *p* tolylhydrazine and pyruvic acid, the di methyl indole carboxylic acid giving with alkaline hypochlorite a chlorinated compound crystallising in yellow needles [135°] which yield the di methyl isatin on dissolving in water (H). Red needles.

Ethyl pseudo isatin $C_6H_4 \begin{smallmatrix} \text{CO} \\ < \text{NEt} > \end{smallmatrix} \text{CO}$ *Lactam of ethyl isatinic acid* [95°]

Formation—1 By the action of a cold alkaline solution of chlorine followed by hot alcoholic NaOH on ethyl indole carboxylic acid [183°] which is obtained by the action of HCl on phenyl ethyl hydrazine pyruvic acid (E Fischer & Hess, *B* 17, 566).—2 By reduction of the di ethyl derivative of pseudo isatin- ω -oxim.

$C_6H_4 \begin{smallmatrix} \text{CO} \\ < \text{NEt} > \end{smallmatrix} \text{C}(\text{NOEt})$ with zinc dust and oxidation of the product with Fe_2Cl_6 (Baeyer, *B* 16, 2193). Large red plates, sol hot water, alcohol and ether. With thiophene and H_2SO_4 it gives a blue colouring matter soluble in ether. It dissolves in alkalis with a yellow colour, at once forming a salt of ethyl isatinic acid $C_6H_4 \begin{smallmatrix} \text{CO CO}_2H \\ < \text{NHEt} > \end{smallmatrix}$.

Ethyl pseudo isatin ω -oxim

$C_6H_4 \begin{smallmatrix} \text{C}(\text{NOH}) \\ < \text{NEt} > \end{smallmatrix} \text{CO}$ [162°] Yellow four-sided prisms. Formed by the action of hydroxylamine on ethyl pseudo-isatin. On reduction with zinc dust followed by oxidation with Fe_2Cl_6 it yields ethyl pseudo isatin. It does not yield indigo on treatment with ammonium sulphide (Baeyer, *B* 16, 2196).

Ethyl pseudo-isatin ω -oxim *Ethyl ether*

$C_6H_4 \begin{smallmatrix} \text{CO} \\ < \text{NEt} > \end{smallmatrix} \text{C}(\text{NOEt})$ [99°] From the ethyl ether of the ω -oxim of ψ -isatin by further ethylation (Baeyer, *B* 16, 2191). Yellow needles, v.

sol alcohol and ether, sl sol hot water. May be sublimed. Insol alkalis. After reduction with zinc dust, on oxidation with $FeCl_3$, it yields ethyl ψ isatin.

Bromo-ethyl-isatin $C_6H_4BrO_2NEt$ s.a.

$C_6H_4Br \begin{smallmatrix} \text{CO} \\ > \text{COEt} \end{smallmatrix} \text{N}$ [109°] From the silver compound of bromo isatin and EtI (Baeyer & Oeconomidis, *B* 15, 2095). Long red prismatic needles (from benzene). On keeping it slowly changes into bromo ethyl isatoid.

Bromo-ethyl isatoid $C_6H_4Br_2N_2O$ [245°] Fine needles. Sparingly soluble in all solvents, most easily in hot alcohol and acetone. Formed by spontaneous change of ethyl bromo isatin by keeping, also by the action of acetic anhydride on ethyl bromo isatin (Baeyer & Oeconomidis, *B* 15, 2095).

p Ethyl-isatin $C_6H_4NO_2$ s.a.

$C_6H_4Et \begin{smallmatrix} \text{CO} \\ > \text{COH} \end{smallmatrix} \text{N}$ [137°] Long red needles (Paucksch, *B* 17, 2805). Formed by heating with $HClAq$ the product of the action of di chloro acetic acid on *p*-amido phenyl-ethane $C_6H_4Et(NH_2)$ [14].

Di-bromo-ethyl-isatin $C_6H_4O_2NBr_2Et$ s.a.

$C_6H_4Br \begin{smallmatrix} \text{CO} \\ > \text{COEt} \end{smallmatrix} \text{N}$ [89°] From silver di-bromo isatin and EtI (B & O). Red crystals. *p* Methyl ψ ethyl- ψ isatin.

$C_6H_4Me \begin{smallmatrix} \text{CO} \\ < \text{NEt} > \end{smallmatrix} \text{CO}$ [110°] **Ethyl ψ -*p*-toluatin**. Formed from the *p*-toluidide by treatment with conc $HClAq$ (Duisberg, *B* 18, 197). Formed also from methyl ethyl indole carboxylic acid by treatment with a weak alkaline solution of NaOCl, and warming the resulting pp with water (Hegel, *A* 232, 219). Red needles or prisms, v sol alcohol, ether, benzene, and CS₂, sl sol water and ligroin. Sol aqueous alkalis. Gives the indophenine reaction.

p-Tolylimide $C_6H_4Me \begin{smallmatrix} \text{CO} \\ < \text{NEt} > \end{smallmatrix} \text{CO}$

***p* Toluidide** [152°] Formed by boiling the *p* tolylimide of *p* methyl isatin with NaOEt and EtBr (Duisberg, *B* 18, 198). Large orange-red prisms, v sol alcohol, acetic acid, benzene, and CS₂, sl sol ether, insol water. Split up by HCl into *p* toluidine and methyl ethyl- ψ isatin.

Isobutyl-bromo-isatin

$C_6H_4Br \begin{smallmatrix} \text{CO} \\ > \text{COC}_4H_9 \end{smallmatrix} \text{N}$. Crystallises with difficulty. Is converted by Ac_2O into iso butyl-bromo isatoid $C_6H_4Br_2O_2$ [210°] which crystallises in slender needles, sl sol all solvents (Baeyer & Oeconomidis, *B* 15, 2097).

Benzyl ψ -isatin $C_6H_4 \begin{smallmatrix} \text{CO CO} \\ < \text{N}(\text{CH}_2\text{Ph}) > \end{smallmatrix} \text{CO}$ [181°].

Formed by adding a solution of sodium benzyl indole carboxylate to one of NaOCl. The pp is dissolved in alcoholic NaOH, warmed gently, diluted with water, freed from alcohol by distillation, and ppd with water (Antriok, *A* 227, 364). Long silky red needles (from water). Almost insol cold water, v sol alcohol and ether.

Phenol-isatin v Di OXY-DI PHENYL-OXINDOLE. Tolu-isatin v Di TOLYL-OXINDOLE

(ϵ)-Naphth-isatin $C_{10}H_7 \begin{smallmatrix} \text{NH} \\ < \text{CO} > \end{smallmatrix} \text{CO}$ or

$C_6H_5 \cdot \begin{smallmatrix} N \\ \diagup \diagdown \\ CO \end{smallmatrix} > COH$ [255°] Formed by dissolving (s) naphthoxindole in alcohol and adding HOAc and $NaNO_2$. The isonitroso derivative so obtained is reduced with Sn and HCl, and subsequently oxidised with $FeCl_3$ (Hinsberg B 21, 117) Red needles Forms a compound with phenyl hydrazine [270°]

(*B*) - Naphth-isatin $C_{10}H_6 \cdot \begin{smallmatrix} N \\ \diagup \diagdown \\ CO \end{smallmatrix} > COH$ [248°]

Formed by dissolving (*B*) naphthoxindole in HOAc and adding sodium nitrite The isonitroso-body formed yields on reduction with Sn and HCl, and subsequent oxidation with $FeCl_3$, the isatin (Hinsberg, B 21, 115) Red needles, v sol ordinary solvents

AMMONIACAL DERIVATIVES OF ISATIN

Imesatin $C_8H_6N_2O \cdot \begin{smallmatrix} CO \\ \diagup \diagdown \\ N \end{smallmatrix} > CNH_2$ or

$C_8H_5 \cdot \begin{smallmatrix} CO \\ \diagup \diagdown \\ NH \end{smallmatrix} > CNH(?)$ or $C_8H_5 \cdot \begin{smallmatrix} C(NH) \\ \diagup \diagdown \\ N \end{smallmatrix} > COH$

Isatin imide (?) Obtained by Laurent (*J pr* 25 457) by passing dry NH_3 into a boiling alcoholic solution of isatin containing a little isatin in suspension Could not be obtained by Sommaruga (*B* 10, 432) Rectangular prisms insol water, v sl sol ether, m sol boiling alcohol Readily decomposed by heating with alcohol and HClAq into isatin and NH_3 KOH acts in like manner

Chloro-imesatin C_8H_5ClNO From chloro-isatin and alcoholic NH_3 (Laurent) Yellow six-sided prismatic tables, v sl sol boiling alcohol, insol ether Dissolves in KOH, giving a red liquid

Bromo-imesatin C_8H_5BrNO From bromo-isatin and boiling alcoholic NH_3 (Gercke, *Z* 1865, 593) Yellowish brown crystalline mass

Iso-amyl-imesatin $C_8H_5(C_4H_9)NO$ $\cdot \begin{smallmatrix} CO \\ \diagup \diagdown \\ N \end{smallmatrix} > CNHC_4H_9$ or

$C_8H_5 \cdot \begin{smallmatrix} CO \\ \diagup \diagdown \\ N \end{smallmatrix} > CNHC_4H_9$ or

$C_8H_5 \cdot \begin{smallmatrix} C(NC_4H_9) \\ \diagup \diagdown \\ N \end{smallmatrix} > COH(?)$ Formed by heating isatin with isoamylamine (Schiff, *A* 144, 53, *Z* [2] 4, 18) Yellow laminae, sl sol ether, v sol alcohol Decomposed by dilute acids or by prolonged treatment with water into isatin and isoamylamine

Phenyl-imesatin $C_8H_5(C_6H_5)NO$ *Amide of isatin* From isatin and aniline in boiling alcoholic solution (Engelhardt, *J* 1855, 541) Formed also by heating the compound of isatin with bisulphite of aniline, and crystallising from ether alcohol

Chloro-phenyl-imesatin $C_8H_5(C_6H_4Cl)NO$ From isatin and chloro aniline (*E*) Yellowish crystals

Bromo-phenyl-imesatin $C_8H_5(C_6H_4Br)NO$ Resembles the preceding (*E*)

Phenyl-chloro-imesatin $C_8H_5Cl(C_6H_5)NO$ Formed by adding aniline to a boiling solution of chloro isatin in alcohol (Engelhardt, *J pr* 65, 260) Yellow needles, insol water, v sol hot alcohol Resolved by boiling dilute acids into chloro-isatin and aniline Potash gives aniline and potassium chloro-isatate.

Phenyl-bromo imesatin $C_8H_5Br(C_6H_5)NO$ Resembles the above (*E*)

Di-phenyl-di-ethyl-di-amide of isatin $C_{24}H_{18}N_4O \cdot \begin{smallmatrix} CO \\ \diagup \diagdown \\ NH \end{smallmatrix} > C(NPhEt)$, or

$C_6H_5 \cdot \begin{smallmatrix} C(NPhEt) \\ \diagup \diagdown \\ N \end{smallmatrix} > COH(?)$ So-called phenyl

ethyl imesatin From isatin by heating with ethyl aniline (Schiff) Yellow laminae, sl sol ether, v sol alkalis Split up by acids, alkalis, or hot water into isatin and ethyl aniline

p-Methyl-imesatin v *Imide of p* Methyl isatin (*supra*)

Phenyl-*p*-methyl-imesatin v. *Amide of p*-methyl isatin (*supra*)

Imasatin $C_{11}H_{11}N_2O$ Formed by passing NH_3 into a boiling saturated solution of isatin in dilute alcohol (Laurent, *A Ch* [3] 8, 493) Greyish yellow granules, insol water and ether, v sl sol boiling alcohol Not attacked by boiling aqueous HCl Caustic potash dissolves it, and the solution is pptd by dilute HClAq

Di-chloro-imesatin $C_{10}H_8Cl_2N_2O$ From chloro isatin and alcoholic NH_3 (*L*) Slightly reddish powder

Di-bromo-imesatin $C_{10}H_8Br_2N_2O$ Formed by heating an alcoholic solution of bromo isatin with ammonia (Gercke, *Z* 1865, 593) Brownish yellow crystalline granules

Tetra-bromo-imesatin $C_{10}H_8Br_4N_2O$ From tetra bromo isatin and alcoholic NH_3 Reddish yellow scale. (*L*)

Amasatin $C_{10}H_8N_2O$ *Isamide Amide of Isamic acid?* One of the products of the action of ammonia on isatin Prepared by heating ammonium isamate till water is given off, and washing the residue with water (Laurent, *A Ch* [3] 3, 488, *J pr* 35, 117) Yellow powder, insol water, nearly insol ether, v sl sol alcohol, m sol boiling alcoholic NH_3 Cold KOHAq dissolves it, giving off NH_3 , and forming a yellow liquid containing potassium isamate HClAq forms a violet solution containing isamic acid

Di-chloro-amasatin $C_{10}H_6Cl_2N_2O$ Yellow powder, formed by evaporating a solution of ammonium chloro isatate (*L*)

Tetra-chloro-amasatin $C_{10}H_4Cl_4N_2O$ Formed by heating ammonium di chloro isatate

Di bromo amasatin $C_{10}H_6Br_2N_2O(?)$ Formed by evaporating an aqueous solution of ammonium bromo isatate and treating the pasty residue with water (Gercke) Orange yellow substance, sl sol water, insol alcohol and ether Dissolves with violet colour in acids

Amisatin $C_{10}H_8N_3O$ A product of the action of dilute alcoholic ammonia on isatin and pptd by adding water to the solution after isatimide and isatium have crystallised out (*L*) Minute needles, insol alcohol, sol alcoholic potash

Isamic acid $C_{10}H_8N_2O$ Produced by the action of warm ammonia on isatin, but is best prepared by dissolving isatin to saturation in aqueous KOH, evaporating the solution to dryness, dissolving in alcohol, adding a very concentrated solution of ammonium sulphate, filtering, and evaporating to dryness The residue contains amasatin and ammonium isamate, and the latter may be dissolved in alcohol, whence, after addition of HCl, isamic acid crystallises (Laurent, *A Ch* [3] 8, 490) Ruby coloured hexagonal tables or scarlet trimetric laminae. Sl. sol. boiling water, forming a yellow

low solution, v sol hot alcohol, m sol ether. Aqueous HCl dissolves it with violet colour, and it separates again from the solution in violet crystals turned red by water. Boiling dilute acids split it up into isatin and ammonia. Bromine forms 'indelbrome', a yellow substance $C_{12}H_7BrN_2O_2$, insol water.

Salts— NH_4A small needles, or very acute minute rhombs. When strongly heated it gives off water and forms amasatin. Its solution does not ppt salts of Ba, Ca, or Mg, but gives a yellow pp with lead acetate and with $AgNO_3$, and a red pp with $HgCl_2$.—The potassium salt may be boiled without decomposing— AgA .

Di chloro isamic acid $C_8H_4Cl_2N_2O_4$. Formed by adding HCl to a solution of di chloro amasatin in dilute KOH and crystallising the brick red pp from alcohol (L). Bright red elongated hexagonal laminae. More sol alcohol and ether than isamic acid. Forms yellow solutions. Decomposed by distillation. HClAq forms a violet solution, but on boiling it is split up into NH_3 and chloro isatin.

Tetra chloro isamic acid $C_8H_2Cl_4N_2O_4$. By boiling tetra chloro amasatin with alcohol and adding silver nitrate a flocculent precipitate of $C_{12}H_4AgCl_4N_2O_4$ is formed (L).

Di bromo isamic acid $C_8H_4Br_2N_2O_4$. Formed by dissolving di bromo amasatin in KOHAq and neutralising with dilute HCl (Gericke). Red powder, nearly insol water, v sol alcohol and ether. HClAq gives a violet solution. Boiling KOHAq gives bromo isamic acid— KA yellow needles, sl sol water— BaA .

Isatimide $C_8H_5N_2O_3$. Formed by passing dry NH_3 over isatin moistened with alcohol (86 to 100 p c). When absolute alcohol is used, imasatin first crystallises out, and the filtrate deposits isatimide as a yellow crystalline powder. Insol water, scarcely sol boiling alcohol or ether, v sol boiling alcoholic NH_3 . Potash dissolves it with yellow colour and evolution of NH_3 , the liquid then containing isatin.

Isatilm $C_8H_5N_2O_3$ (?) Sometimes formed when dry NH_3 is passed over isatin moistened with alcohol, separating from the alcoholic filtrate from which isatimide has separated (Laurent, *J pr* 35, 121). Yellow amorphous flocks, easily decomposed by KOH.

Di isatin diamide $C_{12}H_7N_2O_6$. Formed by saturating an alcoholic solution of isatin with dry NH_3 , and heating to 100° for 24 hours. The product is filtered boiling, the filtrate containing deoxy imido isatin, while the di isatin diamide and oxydiamidosatin diamide which remain on the filter are separated by treatment with water in which the di isatin diamide is the less soluble (L von Sommaruga, *A* 190, 867, *B* 11, 1082, 12, 980). Pale yellow crystals, sl sol alcohol and water. Nitrous acid forms some di isatin amide.

Salts— $BHCl$ yellow crystalline powder, almost insol cold water— $BHNO_2$, yellow needles— $BHSO_4$, yellow needles. Not decomposed by heating with water at 100° — $BHCrO_4$, orange powder.

Di isatin amide $C_{12}H_{11}N_2O_5$, [252°] Formed by warming di isatin diamide with dilute KOH and ppg with HCl (Sommaruga, *M* 1, 579). Small yellowish needles (from alcohol). Scarcely sol. water, v. sol alcohol— $C_{12}H_{11}(NH_2)_2N_2O_5$.

silvery scales— $C_{12}H_9KN_2O_5$, 14aq silvery plates or needles.

Dihydrate $C_{12}H_{11}N_2O_5$, [213°] Formed by treating di isatin amide or di isatin diamide with sodium amalgam (Sommaruga, *A* 194, 88). Slender needles (from alcohol), scarcely sol water and ether. Oxidised by boiling with HgO or aqueous $FeCl_3$ to di isatin amide. Not affected by aqueous KOH (S G 127) at 100° — $NaC_{12}H_{11}N_2O_5$, long colourless needles, v sol hot water— $KC_{12}H_{11}N_2O_5$, broad needles with silky lustre.

Oxy diamido di isatin diamide $C_{12}H_9N_4O_7$, *Oxydimidodiamidosatin* [295°–300°] Formed as above (S). Large colourless needles. Sol water, v e sol alcohol. Dissolves readily in acids, and is not reppd from these solutions by NH_3 . Boiling with water and sodium amalgam converts it into di amido di hydrindic acid. The solutions of its salts show intense red fluorescence— $BHNO_2$, granules, v sol hot water— $BHSO_4$, prisms.

Di amido di hydrindic acid $C_{12}H_9N_4O_7$, [217°] Formed as above. Crystalline granules. Decomposed on fusion. V sol hot water. Oxidised by chromic acid mixture to 'di imido di hydrindin dicarboxylic' acid $C_{12}H_7N_4O_9$, which crystallises from hot water in needles.

Deoxyimido disatin $C_{12}H_9N_2O_5$, [210°] Formed as mentioned under disatin diamide (S), and purified by solution in aqueous KOH and ppg by an acid. Yellowish powder. Decomposed by fusion. V sol alcohol, hot water, and alkalis.

Oxy amido hydro-isatin, so called, $C_{12}H_9N_2O_6$. Formed by treating the preceding body with sodium amalgam or by heating it with KOHAq in sealed tubes at 100° (S). Yellowish amorphous powder, insol water, v sol alcohol. Decomposes at 188° without fusion.

ISATIN CARBOXYLIC ACID *Anilide* $C_{12}H_9NO_4$, i.e. $C_{12}H_9NO$ CONPhH, probably CO

$C_6H_5 < \begin{smallmatrix} \diagup CO \\ \diagdown NCONPhH \end{smallmatrix}$ *Carbanilido isatin* [180°–

183°] Formed by heating isatin for 8 hours at 130° with phenyl cyanate (Gumpert, *J pr* [2] 32, 283). Crystallises from benzene in canary yellow needles. Sol alcohol, ether, and glacial acetic acid.

Reactions—1 When fused it forms isatin and phenyl cyanate (compare the formation of isatin from acetyl isatin).—2 With H_2SO_4 and crude benzene it gives the indophenol reaction. 3 Dissolves in warm dilute KOH forming potassium carbanilido isatate. HCl throws down sparingly soluble carbanilido isatic acid, $NPhH \cdot CO \cdot NH \cdot C_6H_5 \cdot CO \cdot CO \cdot H$, [170°–180°, with decomposition]. The acid is very stable, but by heating at 110° for a long time it loses H_2O , changing back to carbanilido isatin. Carbanilido isatic acid, when heated with ethyl or methyl alcohol, splits off CO_2 and H_2O forming $C_{12}H_{11}N_2O_5$, [175°], and $C_{12}H_{11}N_2O_5$, [197°], respectively.—4 Converted by amines into amides of carbanilido-isatic acid, thus alcoholic NH_3 at 100° forms $NPhH \cdot CO \cdot NH \cdot C_6H_5 \cdot CO \cdot CO \cdot NH_2$, [229°], crystallising from alcohol in needles. It dissolves in dilute NaOH, but is reppd unaltered by HCl. When dissolved in glacial acetic acid it is converted by N_2O_5 into an indifferent body, $C_{12}H_{11}N_2O_9$, [270°].—5. NEt_3 ,

forms $\text{NPhH CO NH C}_6\text{H}_5$, CO CO NEtH [210°] It forms needles (from alcohol) and is a weak acid — 6 *Phenyl hydrazine* forms $\text{NPhH CO NH C}_6\text{H}_5$, $\text{CO CON}(\text{NH}_2)\text{Ph}$ [193°] — 7 *Hydroxylamine* forms

$\text{NPhH CO NH C}_6\text{H}_5$, CO CO NH OH [225°]

ISATIN DIHYDRIDE ν DIOXINDOLE

ISATIN INDOGENINE ν INDIGO

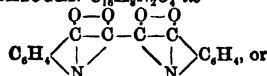

ISATIN SULPHONIC ACID $\text{C}_6\text{H}_4\text{NSO}_3$, $\pm e$

$\text{SO}_3\text{H C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \text{N} \diagdown \end{smallmatrix} \text{CO OH}$ *Isatosulphuric acid*

Preparation—Commercial indigo carmine (18 pts) is stirred up into a thin paste with water (18 pts), H_2SO_4 (1½ pts) is added, and the mixture heated to boiling while $\text{K}_2\text{Cr}_2\text{O}_7$ (1 pt) is gradually thrown in, as long as decolourisation ensues. The hot solution is filtered and KNO_3 added, which facilitates the deposition of potassium isatin sulphonate. The K salt is mixed with resinous matter, which can be got rid of by dissolving in hot baryta water, ppg excess of baryta by CO_2 , and then ppg by K_2SO_4 (G & A Schlieper, A 120, 1). Yellow radio crystalline mass (containing 2aq) Insol ether and benzene, m sol alcohol, v sol water. Powerful acid, separating HCl from its salts. Not decomposed by H_2SO_4 or HNO_3 , even on boiling. Aqua regia slowly forms tetra-chloro quinone. Alcoholic NH_3 forms dark brown bodies. Hydric iodide does not reduce it. Ammonium sulphide forms $\text{SO}_3\text{H C}_6\text{H}_4 \begin{smallmatrix} \text{CH(OH)} \\ \diagup \text{N} \diagdown \end{smallmatrix} \text{COH}$ Hot potash forms sulpho isatic acid.

Salts— NaA 2aq deep-red tables, ppg from its aqueous solution by NaCl — KA aq small golden needles S 5 in the cold. Insol alcohol. Ppd by KNO_3 from its aqueous solution— NH_4A aq deep yellow needles, v sol water, sl sol NH_4Cl — BaA 4aq scarlet powder, insol alcohol, sl sol water— CaA 2aq small golden needles, m sol water— AgA aq. yellow needles, sl sol water.

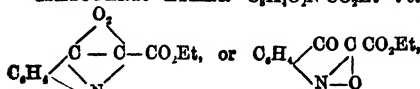

DIISATOGEN $\text{C}_6\text{H}_4\text{N}_2\text{O}_4$, $\pm e$

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO CO CO CO} \\ \diagup \text{N} \diagdown \end{smallmatrix} \text{C}_6\text{H}_4$ (Michael, J pr [2]

85, 256) Prepared by the action of fuming H_2SO_4 on di-*o*-nitro di-phenyl-diacetylene (Bayer, B 15, 52). Red needles. Sol nitro benzene, sl sol chloroform, insol alcohol and ether. With H_2SO_4 and FeSO_4 it gives indom. It is very readily reduced to indigo by cold NH_4HS , by zinc-dust, and NH_4NaOH or AcOH , by glucose, and alkalis, &c. It combines with ammonium bisulphite.

ISATOGENIC ETHER $\text{C}_6\text{H}_4\text{O}_2\text{N CO}_2\text{Et}$, $\pm e$.

or $(\text{CO}_2\text{Et CO CO C}_6\text{H}_4)_2\text{N}_2$ (Michael, J pr [2] 85, 255) [115°] Formed by an isomeric change from *o*-nitro phenyl-propionic ether by the action of cold H_2SO_4 (Bayer, B 14, 1741, 15, 780). Yellow needles. By most reducing agents it is reduced to indoxyl ether, but ferrous salts give indoxanthic ether (Bayer, B 15, 780). Isato-

genic acid is perhaps formed by shaking *o*-nitrophenyl propionic acid with H_2SO_4 , but if so, it is decomposed on diluting with water into CO_2 and isatin.

ISATOIC ACID $\text{C}_6\text{H}_4\text{NO}_3$, $\pm e$ $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \text{N} \diagdown \end{smallmatrix} \text{CO}_2\text{H}$

Anthranil carboxylic acid [230°] S (acetone) 4 & 4 at 55°

Formation—1 By the oxidation of isatin by CrO_3 in HOAc (Kolbe, J pr [2] 80, 469).—2 By heating anthranil with chloro formic ether at 30° (Friedlander & Wleügel, B 16, 2227).—3 By boiling *o*-amido benzoic acid with excess of chloro formic ether (Niementowski & Rozanski, B 22, 1672).

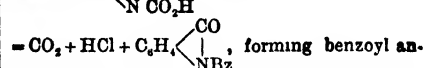

Preparation—(H Kolbe, J pr [2] 30, 469) Isatin (100 g) is powdered and mixed with glacial acetic acid (600 g). A solution of CrO_3 (200 g) in glacial acetic acid (600 g) is slowly added, the temperature being kept below 50°. The flask is left for 12 hours in cold water, and then in water at 50°, and finally at 60°. Isatoic acid then begins to separate as a yellow powder, the separation is completed by pouring into 500 c.c. cold dilute H_2SO_4 . Yield 72 per cent.

Properties—Nearly rectangular prisms, which are yellow (through some impurity) when prepared from isatin. Decomposed at 230°. Sparingly soluble in alcohol, ether, and glacial acetic acid, rather more soluble in chloroform and benzene.

Reactions—1 Boiled with water it forms *o*-amido benzoic (anthranilic) acid $\text{C}_6\text{H}_4\text{NO CO}_2\text{H} + \text{H}_2\text{O} = \text{C}_6\text{H}_4(\text{NH})\text{CO}_2\text{H} + \text{CO}_2$.—2 Conc HCl , H_2SO_4 , and dilute HNO_3 behave in the same way.—3 Gaseous HCl passed into an alcoholic solution forms the hydrochloride of *o*-amido benzoic ether.—4 Aqueous baryta forms, on warming, *o*-amido benzoic acid.—5 *Ammonia* (aqueous or dry) forms *o*-amido benzamide.—6 *Aniline* at 60° forms the anilide of *o*-amido benzoic acid.—7 HNO_3 (SG 148) forms nitro isatoic acid.—8 *Nitrous acid gas* passed into water, containing isatoic acid suspended, forms (a) nitro salicylic acid. Anthranilic acid is doubtless first formed, and this is then nitrated and exchanges NH_2 for OH .—9 Heated with methyl or ethyl alcohol it unites, forming crystalline compounds, carboxylic acids of the methyl or ethyl ethers of *o*-amido benzoic acid.

The acid $\text{CO}_2\text{H NH C}_6\text{H}_4\text{CO}_2\text{Me}$ crystallises in needles [176°], while the corresponding $\text{CO}_2\text{H NH C}_6\text{H}_4\text{CO}_2\text{Et}$ forms needles [126°].—10 With benzoyl chloride at 210° it partly reacts

thranyl [123°].—11 *Bromine* forms bromo isatoic acid, which gives with HCl (β) bromo anthranilic acid [208°].—12 It dissolves in cold dilute NaOH with a blue fluorescence, but on standing the fluorescence vanishes and the solution then contains anthranilic acid (Friedlander & Wleügel, B 16, 2227).—13 *Phenol* at 180° gives phenyl

o-amido benzoate crystallising in needles [70°] (G Schmidt & E v Meyer, *J pr* [2] 36, 370) — 14 Long boiling with glacial *acetic acid* forms an amorphous compound $C_{10}H_7N_3O_6$, v sl sol ordinary solvents, which yields *o* amido benzoic acid when heated with HCl or dilute H_2SO_4 (G Schmidt, *J pr* [2] 36, 380) — 15 Heating with Ac_2O gives acetyl *o* amido benzoic acid [180°] (S) — 16 With *hydroxylamine* it forms *o* amido-benzoyl hydroxylamine (E v Meyer & T Bell-

mann, *J pr* [2] 33, 19) $C_6H_4 \begin{smallmatrix} \diagup CO \\ | \\ N \\ \diagdown CO_2H \end{smallmatrix} + H_2NOH$
 $= C_6H_4(NH_2)CO NH(OH) + CO_2$ — 17 With *phenyl hydrazine* it forms *o* amido benzoyl phenyl-

hydrazine $C_6H_4 \begin{smallmatrix} \diagup CO \\ | \\ N \\ \diagdown CO_2H \end{smallmatrix} + PhNH NH_2$
 $= C_6H_4(NH_2)CO NPh NH_2 + CO_2$ — 18 It does not react with boiling *di-methyl aniline* — 19 *Pyrocatechin* at 180° reacts thus (M & B).

$C_6H_4(OH)_2 + C_6H_4 \begin{smallmatrix} \diagup CO \\ | \\ N \\ \diagdown CO_2H \end{smallmatrix}$
 $= CO_2 + C_6H_4(NH_2)CO O C_6H_4OH$, forming *o* oxyphenyl *o* amido benzoate — 20 Boiled with *formic acid* it forms formyl *o* amido benzoic acid and a weak base, $C_8H_7N_3O_6$. This crystallises in rhombohedra (from alcohol) It melts at [280°], with decomposition Sparingly soluble in water, alcohol, benzene, and chloroform S (ether) 03 at 15°, S (alcohol) 11 at 19° Readily soluble in NaOH, Aq, forming a crystal line salt Its hydrochloride forms prisms, but is decomposed by water Heated with conc HCl at 140° it forms CO_2 , formic acid, and the hydrochloride of anthranilic acid (M & B) — 21 By treatment with PCl_5 in presence of $POCl_3$ a product is got whence methyl alcohol and ethyl alcohol respectively form crystalline products The former gives $C_{10}H_7N_3O_6$ [210°], small needles The latter gives $C_8H_7N_3O_6$ [170°], needles With conc HCl at 140° the latter gives EtCl and anthranilic acid (M & B) — 22 *Blackening powder* suspended in chloroform changes some of the isatoic acid into an isomer [240°], soluble in alcohol, acetone, and benzene It dissolves in NH_3 , Aq without forming anthranilamide (unlike isatoic acid), but when HCl is added to the solution an acid [260°] is ppd (M & B) — 23 Heated with glacial *acetic acid* and *bromine* (1 mol) it forms bromo isatoic acid, but with more bromine CO_2 is evolved, and di-, tri-, and tetra-bromo amido benzoic acids are got.

Chloro-isatoic acid $C_6H_4Cl \begin{smallmatrix} \diagup CO \\ | \\ N \\ \diagdown CO_2H \end{smallmatrix}$

[α 268°] From chloro isatin (10 g), CrO_3 (20 g) and glacial *acetic acid* (120 g) as described under bromo isatin (Dorsch, *J pr* [2] 33, 49)

Properties — Pearly plates (from alcohol-ether) Sl sol alcohol, acetone, and glacial *acetic acid*, insol benzene, chloroform, ether, and water

Reactions — 1 Conc HCl forms chloro-*o*-amido-benzoic acid [204°] — 2 Hot NH_3 , Aq forms the amide of chloro amido benzoic acid

Di-chloro-isatoic acid $C_6H_2Cl_2 \begin{smallmatrix} \diagup CO \\ | \\ N \\ \diagdown CO_2H \end{smallmatrix}$

[256°]

Formation. — By oxidation of di chloro-isatin.

Properties — Yellow prisms (from alcohol-acetone) Melts at 254°-256° with decomposition V sol acetone and glacial *acetic acid*, sol alcohol and chloroform, v sl sol ether and benzene Boiled with water it partly changes to di chloro *o* amido benzoic acid, as shown by its violet fluorescence (Dorsch, *J pr* [2] 33, 51).

Reactions — 1 Conc HCl slowly converts it, on boiling, into di chloro amido benzoic acid [224°] — 2 With NH_3 , Aq it gives di-chloro amido benzamide

Bromo isatoic acid $C_6H_4Br \begin{smallmatrix} \diagup CO \\ | \\ N \\ \diagdown CO_2H \end{smallmatrix}$

[α 275°]

Formation — 1 By oxidising bromo isatin. 2 From Br and isatoic acid suspended in glacial *acetic acid* at 90° (R Dorsch, *J pr* [2] 33, 32)

Properties — Pearly plates (from a mixture of alcohol and acetone) Sol acetone Sl sol alcohol and glacial *acetic acid* Insol water, chloroform, ether, and benzene

Reactions — 1 With boiling conc hydrochloric acid it forms (β) bromo amido benzoic acid $C_6H_4Br(NH_2)CO_2H$ — 2 With hot NH_3 , Aq it gives bromo amido benzamide

Di bromo isatoic acid $C_6H_2Br_2 \begin{smallmatrix} \diagup CO \\ | \\ N \\ \diagdown CO_2H \end{smallmatrix}$

[255°] Obtained by oxidising di bromo isatin (10 g) by CrO_3 (10 g) in presence of glacial *acetic acid* (60 g) as described under bromo isatin

Properties — Flesh coloured prisms (from alcohol-acetone) Sol glacial *acetic acid* and acetone, sl sol alcohol, chloroform, and benzene, hardly sol ether, insol water Much more stable than bromo isatoic acid

Reactions — 1 Boiled for a long time with conc HCl it gives off CO_2 , leaving di bromo *o*-amido benzoic acid — 2 It does not dissolve in NH_3 , Aq But if heated with it at 100° for a long time it forms di bromo amido benzamide $C_6H_2Br_2(NH_2)CO NH_2$ [197°]

Nitro-isatoic acid $C_6H_4(NO_2)NO CO_2H$ [220°-230°] Formed by the action of HNO_3 (S G 148) on isatoic acid Insol water and ether, sl sol alcohol Crystallises from equal parts of alcohol and acetone in pearly plates It resembles isatoic acid, splitting up readily into CO_2 and nitro-*o* amido benzoic acid, when boiled with HCl or even with water Nitro-isatoic acid is converted by aqueous NH_3 into nitro amido benzamide By Sn and HCl it is reduced to di-amido benzoic acid, CO_2 escaping Bromine (in glacial *acetic acid*) converts it into mono-, di-, and tri-nitro-amido benzoic acids (q v)

Methyl-isatoic acid $C_6H_4Me \begin{smallmatrix} \diagup CO \\ | \\ N \\ \diagdown CO_2H \end{smallmatrix}$

Preparation — Methyl-isatin (10 g) is mixed with glacial *acetic acid* (60 g) and cooled well while a mixture of CrO_3 (21 g) in glacial *acetic acid* (60 g) is slowly added After 12 hours at 0° the mixture is heated for 2 hours at 40° and then to 70° It is poured into water containing H_2SO_4 , and the yellow powder crystallised from absolute alcohol (Panaotović, *J pr* [2] 31, 123, 33, 58)

Properties — Pale-yellow crystalline plates

(from boiling alcohol) or trimetric columns (from acetone) At 245° it suddenly increases in bulk, but it melts above 800°, giving off CO_2 . V sl sol. water, readily sol boiling alcohol, ether, benzene, and chloroform

Reactions — 1 Is more stable than isatoic acid, not being decomposed by dilute mineral acids. — 2 HNO_3 (S G 1 48) dissolves it in the cold After 12 hours water is slowly added, and the pp crystallised from benzene It forms pale yellow trimetric plates of nitro methyl-isatoic acid [175°] This acid is reduced by Sn and HCl to a di-amido-toluic acid — 3 Warmed with HCl (S G 1 2), CO_2 is given off, and the hydrochloride of amido p toluic acid [207°] formed — 4 Warmed with NH_4Aq it gives the amide of amido toluic acid [178°] — 5 With *aniline* in alcohol it forms the corresponding anilide [243°] — 6 With *phenyl hydrazine* it forms the corresponding hydrazone — 7 With MeOH at 180° it forms methylic amido-toluate

Methyl-isatoic acid $\text{C}_8\text{H}_7\text{NO}_4$, \pm

an amido-toluic acid $\text{C}_8\text{H}_7\text{Me}(\text{NH}_2)\text{CO}_2\text{H}$ [5° or 8? 1 2] with chloro formic ether (Niemen towsky a Rozansky, B 22, 1675) Needles or scales, v sl sol benzene and ether, sl sol alcohol Decomposed on fusion Acids and alkalis decompose it into CO_2 and amido toluic acid [177°]

Isomeride of isatoic acid ψ ANTHROXANIC ACID

ISATYDE $\text{C}_{10}\text{H}_7\text{N}_2\text{O}_4$ Produced by the reduction of isatin by zinc and dilute H_2SO_4 by alcoholic ammonium sulphide, or by zinc dust and HOAc (Laurent, A Ch [3] 3, 382, A 72, 285, Erdmann, J pr 24, 15, 25, 438, Baeyer, B 12, 1309) Formed also by atmospheric oxidation of an aqueous solution of dioxindole (Baeyer a Knop, A 140, 10) White powder, with slightly greyish tint, almost insol water, v sl sol boiling alcohol and ether Separates from boiling alcohol in minute scales Decomposed by heat, becoming at first violet-brown Alcoholic potash forms isatoic acid, indin, and other products

Di-chloro-isatide $\text{C}_8\text{H}_5\text{Cl}_2\text{N}_2\text{O}_4$ Formed by the action of ammonium sulphide on chloro-isatin White powder, crystallisable, insol cold, v sl sol hot, water, m sol boiling alcohol, sol. hot aqueous potassium sulphide At 180° it is resolved into chloro-isatin and chloro-indin Boiling aqueous or alcoholic potash forms potassium chloro isatate and the salt $\text{C}_8\text{H}_5\text{Cl}(\text{NH}_2)\text{CH}(\text{OH})\text{CO}_2\text{K}$

Tetra-chloro-isatide $\text{C}_8\text{H}_3\text{Cl}_4\text{N}_2\text{O}_4$ Produced by the action of ammonium sulphide on di-chloro-isatin White powder, insol water Decomposed by heat into di-chloro isatin and di-chloro indin Alcoholic potash forms di chloro isatin and di chloro-o amido-o-oxy phenyl acetic (di-chloro hydrindic) acid

Tetra-bromo-isatide $\text{C}_8\text{H}_3\text{Br}_4\text{N}_2\text{O}_4$ From di-bromo isatin and ammonium sulphide Resolved by heat into di-bromo-isatin and di-bromo-indin

Thio-isatide $\text{C}_8\text{H}_7\text{N}_2\text{O}_3\text{S}$ Formed by slowly adding alcoholic potash to an alcoholic solution of di thio isatide (Laurent, A Ch [3] 8, 463)

White crystalline powder May be crystallised as minute rectangular scales from hot alcohol Insol water, v sl sol boiling alcohol and ether. Cold potash forms indin and other products Hot potash forms the hydride of indin

Di-thio-isatide $\text{C}_8\text{H}_7\text{N}_2\text{O}_2\text{S}_2$ When H_2S is passed into a conc alcoholic solution of isatin the liquid becomes pale yellow and on cooling deposits crystals of sulphur and of isatide The filtrate when mixed with water deposits di thio-isatide (Laurent) Yellowish grey amorphous powder Decomposed by heat Insol boiling water, v sl warm alcohol and ether Ammonium bisulphite converts it into 'ammonium sulphisatamite' $\text{NH}_4\text{C}_8\text{H}_7\text{NSO}_4$, which crystallises in large pale yellow tables v sol water, m sol alcohol

Di-bromo-di-thio-isatide $\text{C}_8\text{H}_5\text{Br}_2\text{N}_2\text{O}_3\text{S}_2$ Formed, together with di bromo tri thio isatide, when H_2S is passed into a boiling alcoholic solution of bromo isatin (Gericke, Z 1865, 595). Yellowish white powder, insol hot water, sol hot alcohol and ether

Di-bromo-tri-thio-isatide $\text{C}_8\text{H}_5\text{Br}_3\text{N}_2\text{O}_3\text{S}_3$ Formed as above Yellowish white powder

Isatane $\text{C}_{10}\text{H}_{11}\text{N}_2\text{O}_4$ Formed, as a white pp, when di-thio isatide is boiled with a solution of ammonium bisulphite (Laurent, J pr 28, 346) Formed also by the action of sodium amalgam on an acid solution of isatin (Knop, J pr 97, 65) Small white cubes (from ether or hot alcohol), insol water Decomposed by hot alcoholic potash into dioxindole and indirubin Its alcoholic solution gives with ammoniacal AgNO_3 a white pp of $\text{Ag}_2\text{C}_{10}\text{H}_{11}\text{N}_2\text{O}_4$

ISETHIONIC ACID $\text{C}_8\text{H}_7\text{SO}_4$, \pm

$\text{HOCH}_2\text{CH}_2\text{SO}_3\text{H}$ *Oxy ethane sulphonic acid*
Sulphonic acid of ethyl alcohol Mol w 126

Formation — 1 Discovered by Magnus in 1833 (P 27, 378, A 6, 163) as a product of the action of SO_2 on alcohol or ether Hence it is found among the residues in the preparation of ether — 2 By boiling ethionic acid with water (Magnus, A 32, 251) — 3 By the action of SO_2 on barium ethyl sulphate (Meves, A 143, 196) — 4 By the action of nitrous acid on taurine $\text{NH}_2\text{CH}_2\text{CH}_2\text{SO}_3\text{H}$ (W Gibbs, Am S [2] 25, 30) — 5 By heating chloro ethyl alcohol (chlorhydrin of glycol) with aqueous Na_2SO_3 at 175° (Collmann, A 148, 101) — 6 By heating ethylene oxide with aqueous KHSO_3 at 100° (Lrilenmeyer a Darmstadter, Z 1868, 342) — 7 Probably formed by boiling ethylene bromide with aqueous Na_2SO_3 (James, C J 43, 44) — 8 E J oxidising thio glycol $\text{HOCH}_2\text{CH}_2\text{SH}$ with nitric acid (Carius, A 124, 260)

Preparation — SO_2 is added, with shaking, to an equal weight of ether at 0° As soon as a sample mixed with water gives a heavy oil the whole is poured into water and the ethyl sulphate washed with water till neutral, dried over H_2SO_4 , treated with its own weight of SO_2 , and then poured into water The two aqueous liquids are boiled for a long time to decompose ethionic acid, and then neutralised by baric carbonate, on evaporating baric isethionate is got (R Hübner, A 223, 212)

Properties — Viscid, strongly acid syrup, which gradually dries up to a deliquescent radio crystalline mass Is not decomposed at 150°, but blackens at a higher temperature Its

salts are not decomposed by boiling with water, and may even be heated to 200°, above which temperature, however, they lose water and change to di isethionates. Potash fusion gives potassium carbonate, oxalate, sulphate, and sulphite. Berthelot (*Z* 1869, 682) obtained acetylene, K_2SO_4 , and hydrogen PCl_5 yields $CH_2ClCH_2SO_2Cl$, which is converted by heating with aqueous ammonia into taurine (Kolbe, *A* 112, 241). Chromic acid oxidises isethionio acid to sulpho acetic acid $CO_2HCH_2SO_3H$.

Salts— NH_4A' octahedra [130°] (Strecker), [185°] (Seyberth, *B* 7, 391). At 235° it changes to ammonium di isethionate (Carl, *B* 12, 160.)— KA' rhomboidal prisms, melting between 300° and 350° with loss of weight. May be crystallised from alcohol— BaA' , transparent six sided plates [32°]. V sol water S (60 p alcohol) 6 at 14°— CaA' , 2aq pale green prisms— AgA' very hygroscopic pearly needles.

Double salts with Et_2SO , (Engelcke, *A* 218, 270). From NaA' , H_2SO_4 , and alcohol, and conversion into barium salt BaA'_2Et_2SO (?)— $NaATf, SO_4$.

Double salt with Me_2SO ,— $NaA'Me_2SO$, Silky monoclinic tables (from alcohol), very hygroscopic. Decomposed by water at 80°, thus

Ethyl derivative $EtOCH_2CH_2SO_3H$ Sulphonic acid of ether SG ²¹ 1359. The sodium salt is obtained by the action of chloro ethane sulphochloride on excess of $NaOEt$ (R Hubner, *A* 223, 218). Also from $CH_2ClCH_2SO_3Na$ and $NaOEt$. The free acid is got by boiling with water the product obtained by acting with H_2S on the (molecular?) compound of its lead salt with lead ethyl sulphate. It is a syrup.

Salts— NaA' Plates S (alcohol) 27 at 15°— NaA' 3aq Columns— BaA' 3aq— ZnA' 6aq Hygroscopic plates— CaA' 6aq.

Double compounds with the salts of ethyl sulphuric acid $EtSO_3H$. Got by adding H_2SO_4 and alcohol to $EtOCH_2CH_2SO_3Na$, filtering from Na_2SO_4 , and neutralising with a metallic carbonate. The general formula is $C_2H_5SO_3H.C_2H_5OCH_2CH_2SO_3H$ or $C_2H_5S_2O_6H$, e.g. BaA' 3aq Silky scales— $(NH_4)A'_2$, PbA'_2 , NaA'_2 , AgA'_2 , ZnA'_2 , CaA'_2 . These salts are very soluble in water. The free acid splits up on boiling with water, in the following manner $C_2H_5SO_3H.EtOCH_2CH_2SO_3H + H_2O = EtOC_2H_5SO_3H + H_2SO_4 + EtOH$.

Ethyl ether $HOCH_2CH_2CH_2SO_3Et$ From AgA' and EtI (Stempnewsky, *J R* 1892, 95).

Ethyl derivative of the ethyl ether $EtOCH_2CH_2SO_3Et$ SG ¹² 1168 (impure). From $CH_2ClCH_2SO_3Cl$ and $NaOEt$ in ether. Not obtained quite pure.

Benzoyl derivative $BzOCH_2CH_2SO_3H$ From potassium isethionate and $BzCl$ (Engelhardt & Latschnoff, *Z* 1868, 235)— KA' Leaflets, v sol boiling water, sol hot alcohol— BaA' 3aq Large thin tables, m sol cold water, sol boiling alcohol.

Chloride $HOCH_2CH_2SO_3Cl$ Probably formed, together with $CH_2ClCH_2SO_3H$ and $CH_2ClCH_2OSO_3Cl$, by the action of SO_2 on ethyl chloride, or of $ClSO_3H$ on ethylene (Furgold, *B* 6, 504). Excess of SO_2 converts it into the

chloride of ethionio acid (Claesson, *J pr* [2] 19, 253).

Di-isethionio acid $O(CH_2CH_2SO_3H)_2$. **Di sulphonic acid of ether**. The ammonium salt of this acid is obtained by heating ammonium isethionate to 210° (Carl, *B* 12, 1604)— $(NH_4)A''$ [198°] Slender leaflets or scales, v e sol, water— BaA'' 3aq prismatic tables. Formed by heating barium isethionate to 200° (Carl, *B* 14, 65).

ISINGLASS & PROTEIDS, Appendix C.

ISO- Compounds whose names begin with iso are usually described either under the name to which iso- has been prefixed or else under their systematic names as described in the *Introduction to Articles Relating to Organic Chemistry*, vol 1.

ISOMERISM Even a superficial reader of chemical literature will soon become aware that the term *isomeric* and the kindred expressions *allotropic*, *metameric*, and *polymeric* are by no means always used in consistent senses, and he will have considerable difficulty in clearly realising their exact and relative import, it, therefore, appears desirable to discuss the meanings of these terms, especially from the historical side, and as far as possible to define the sense in which they are severally applicable. The following extracts from the article *Isomerism* in the first edition of this Dictionary, vol iii p 415, 1865, by J A Wanklyn, serve to show what views were held at the very outset of the period when the investigation of isomeric substances began largely to engage the attention of chemists—

'Isomerism.—This term is derived from *isos* equal, and *meros* a part, and its employment by chemists is an expression of the fact that very different chemical compounds have sometimes identically the same ultimate composition. Two or more different bodies which are composed of the same elements and of the same proportions of these elements (i.e. which have the same percentage composition) are said to be *isomeric*. Isomerism is sometimes used in a narrower sense, being made to signify equality of molecular weight, as well as identity in percentage composition. When the compounds have the same percentage composition but different molecular weights, the term *polymeric* is employed. Thus there are the terms *isomeric* (in its wide sense), signifying that the different bodies have the same percentage composition, *Polymeric*, signifying that these different bodies have the same percentage composition, but different molecular weights, *Isomeric* (in its restricted sense), sometimes called *Metameric*, signifying that the bodies have the same percentage composition, and likewise the same molecular weight.'

As examples, Wanklyn then cites butyric acid, ethylic acetate, aldehyde, and ethylenic oxide as *isomeric* compounds, using the term in its widest sense of these butyric acid and ethylic acetate are said to be *polymeric* with aldehyde and ethylenic oxide, butyric acid being *isomeric* (in the restricted sense) or *metameric* with ethylic acetate, aldehyde and ethylenic oxide being also metameric compounds. Subsequently, throughout his article, Wanklyn uses the term *isomeric* in its wide sense, substituting the term *metameric* for *isomeric* used in its restricted sense, thus he speaks of methyl, the simplest alcohol radiole, as metameric with ethyl hydride (his article was written at a time when Schorlemmer's investigation was not fully recognised as affording proof of their identity), he points out that several metameric hexanes are possible, and even quotes 'as a very remarkable

example of metamerism' the different varieties of tartaric acid and racemic acid

The term *allotropy* is made use of by Wanklyn in an unusually wide sense. Thus he says—

'Closely related to the term isomerism is the term *allotropy*. Both of them have reference to the same substantial fact, viz that different substances have sometimes the same ultimate composition, but they differ in their manner of stating it. Isomeric and allotropic are in fact complementary terms, "isomeric" being employed to predicate identity of composition between different bodies, whilst "allotropic" expresses difference between bodies of identical composition. Such being the force of these words, there is a certain propriety in their usage. Thus, whilst it is correct to say "butyric acid and acetic ether are isomeric," it should be "there are *allotropic* bodies of the formula $C_4H_8O_2$." The same reason which enjoins the use of allotropic in this case prescribes it in the instance of single elements: thus, for example, we read of "allotropic kinds of sulphur," but never of isomeric kinds. It is worthy of remark that cases of isomerism occurring in inorganic chemistry are usually described by employing the word allotropy or allotropic, while the reverse obtains in organic chemistry. This may be partly ascribed to there being always a very wide difference—or else no difference at all—in the composition of any definite inorganic substances, and hence the fact of identity or non identity of composition being so easily ascertainable. It is implied in the form of expression, whilst the fact of difference of properties alone needs to be made the subject of formal predication. Among organic bodies, on the other hand, it continually happens that the differences of composition are quite decided, and yet so very minute as to tax the utmost powers of chemical analysis for their recognition, and hence the superior dignity which the mere affirmation of identity of ultimate composition acquires in the organic department of the science. The principal examples of allotropy or isomerism, &c. of the co-existence of identical ultimate composition with difference of properties will now be considered.

He then cites the olefines as examples of polymerism, and afterwards discusses numerous cases of metamerism, several of which were referred to above.

Under the heading *Isomers among Inorganic Substances* the following interesting passages occur at the conclusion of the article—

'As before remarked, the instances of inorganic isomerism are usually called instances of allotropy—*isomeric substances and allotropic substances* being nearly equivalent expressions. The elementary substances themselves offer many examples of isomerism. Ozone and oxygen are isomeric bodies. Experiment has shown that the molecular formula for ozone is higher than that for oxygen, but how much higher remains an open question. Sulphur, phosphorus, carbon, and many other elements present somewhat similar examples of allotropy or isomerism. Inorganic compounds, such as the various forms of silicic acid, of sesquioxide of iron, of sesquioxide of chromium, of alumina, must be classed among substances affording examples of isomerism. The explanation of the existence of isomerism will have become sufficiently clear from the course which has been followed in describing the different examples of it. "It is of consequence how the atoms of a compound are arranged, as well as what kind of atoms they are, and hence there may be very many totally different substances composed of the same ultimate atoms. This is in fact the whole philosophy of isomerism."

The definitions given in Kekulé's *Lehrbuch* (1867) are substantially the same as those adopted by Wanklyn, but he specially draws attention to the existence of compounds *isomeric in a restricted sense*, which, according to the state of knowledge of the time, were to be represented by the same rational formulae, although they either were possessed of different properties—as in the case of the C_4H_8 hydrocarbons and of maleic and fumaric acids, or they were in all essential respects chemically identical but physically different—such as the tartaric acids, mucic and saccharic acids, &c. The existence of compounds such as these latter, in fact, gave rise to the re-

cognition of a distinct kind of isomerism, termed *physical isomerism*.

In the latest edition of Watts' *Fownes* by Tilden (1886), polymerism is included under isomerism, but compounds of the same molecular weight are sub-divided into (1) *metameric bodies*, namely, those which exhibit dissimilar transformations under similar circumstances propionic acid, methylic acetate, and ethylic formate are quoted as examples, and (2) *isomeric bodies, strictly so-called*, namely, those which exhibit the same or closely similar decompositions and transformations when subjected to the action of the same reagents, such as the C_4H_{10} hydrocarbons, the glucoses, the tartaric acids, &c.

It will be noted how incompatible are the definitions given by Wanklyn and in *Fownes* of the term *metameric*, it has, however, undoubtedly been customary of late years to employ the term *metameric* in the sense indicated in *Fownes*.

In McGowan's translation of Berntsen's *Organic Chemistry* (1889), the most modern book of its kind, polymerism is not reckoned under isomerism, but the definition given of metamerism is on the whole more in agreement with that quoted from Watts' *Fownes*, after it has been explained that ethers such as methyl amyl ether, ethyl butyl ether, and dipropyl ether are isomeric, we read—

'Such isomerism which depends upon the grouping together by a polyvalent element of alcohol radicals which are individually unequal, but the sum of whose elements taken together are equal, is called *metamerism*. One of the alcohol radicals may here be replaced by hydrogen. Alcohols and ethers containing an equal number of carbon atoms are therefore *metameric*.'

We further learn that the isomerism of the higher paraffins, since it is based upon the dissimilarity of the carbon chains, is often termed *chain isomerism*, that the isomerism between ethylene and ethylidene chlorides, or between primary and secondary propyl alcohols, as it depends upon the difference in position of the substituting halogen or hydroxy in the same carbon chain, is termed *isomerism of place or position*, and that there is the third kind of isomerism, viz *metamerism*. But obviously two different kinds of relationship are thus included under metamerism that of position isomerism, which obtains among the ethers themselves, which are necessarily all compounds of one primary type, and that which obtains between the typically different 'equi molecular' alcohols and ethers, or true metamerism, if the Watts *Fownes* definition be adopted.

If we consider the origin of the four terms under consideration we find that they were all devised by Berzelius. The term *isomeric* is proposed in his *Jahresbericht*, handed in to the Swedish Academy of Sciences, March 31, 1831 (*cf* Wohler's German translation, 1832, pp 44-8), in the following words—

'Da es nothwendig ist, für gegebene Ideen bestimmte, und so viel wie möglich consequent gewählte, Ausdrücke zu besitzen, so habe ich vorgeschlagen, Körper von gleicher Zusammensetzung und ungleichen Eigenschaften *isomerische* zu nennen, vom griechischen *isomeros* (aus gleichen Theilen zusammengesetzt).'

In the next volume of his *Jahresbericht* (Wöhler's translation, 1833, p 63) he gives a

further all important definition of the use he would make of the term, thus —

‘Um jedoch nicht Erscheinungen von nicht völlig gleicher Art mit einander zu verwechseln, ist es nothwendig den Begriff vom Worte *Isomerie* genau zu bestimmen. Ich erwähnte dass ich darunter Körper verstand, die aus einer gleichen absoluten und relativen Atomen-Anzahl derselben Elemente zusammengesetzt sind und gleiches Atomgewicht haben *womit nicht der Fall zu verwechseln ist, wo die relative Anzahl der Atome gleich ist, die absolute aber ungleich.* So ist z. B. die relative Anzahl von Kohlenstoff- und Wasserstoff-Atomen im bildlichen Gas und im Weindol absolut gleich, allein in einem Atom vom Gase sind bloss 1 Atom Kohlenstoff und 2 Atome Wasserstoff enthalten, CH_4 , während dagegen im Weindol 4 Atome Kohlenstoff und 8 Atome Wasserstoff enthalten sind, C_4H_8 . Um diese Art von Gleichheit in der Zusammensetzung bei Ungleichheiten in den Eigenschaften bezeichnen zu können, möchte ich für diese Körper die Benennung *polymerische* (von *πολυς*, mehrere) vorschlagen.’

It will be clear from this quotation, especially from the words which I have italicised, that Berzelius is never intended that polymerism should be regarded as a form of isomerism.

The following passage from the same source clearly exhibits Berzelius's intention as to the use which should be made of the term *metamerism* —

‘Allein es gibt noch andere Verhältnisse, wo Körper, im eigentlichen Sinne des Wortes, isomerisch scheinen, d. h. dieselbe relative und absolute Atomenanzahl derselben Elemente enthalten können, ohne *jedoch vollständig zu sein*. Ein solcher Fall ist wenn Körper aus zwei zusammengesetzten Atomen der ersten Ordnung bestehen, die sich auf verschiedene Weise gegen einander verhalten, und in Folge dessen ungleiche Körper bilden können, z. B. SnS (SnO_2S), schwefelsaures Zinnoxydul, und SnS (SnO_2S_2), basisches schwefelsaures Zinnoxyd, enthalten eine gleiche absolute und relative Anzahl derselben Elemente, und haben dasselbe Atomgewicht, können jedoch nicht als ein und derselbe Körper betrachtet werden. Bei solchen Körpern ist es der Fall, dass wenn sie eine gewisse Zeitlang bestanden haben, oder wenn die Temperatur geändert wird, eine Umlegung der Bestandtheile in ihnen vor sich geht, ohne dass etwas hinzukommt oder davon wegeht, und dass dadurch eine anders beschaffene Verbindung entsteht, welche Veränderung nicht selten von einer Temperatur-Erhöhung begleitet ist. Um solche Fälle bestimmt von Isomerie zu unterscheiden, können wir dafür die Bezeichnung *metamerische* Körper gebrauchen (von *μετα* in der selben Bedeutung wie in Metamorphose).’

Berzelius also cites cyanic and cyanuric acids, which were not then regarded as compounds of different molecular weight, as instances of metamerism, regarding the conversion of the latter into the former on heating as a case in which ‘die Cyanursäure von einem zusammengesetzten Atom der ersten Ordnung, oder einem Oxyd eines ternären Radicals, in ein zusammengesetztes Atom der zweiten Ordnung, nämlich in Cyansäure mit chemisch gebundenem Wasser übergeht’ Cyamelide, into which cyanic acid spontaneously changes, and cyanuric acid, in Berzelius's opinion, were (wenigstens vorläufig) isomeric oxides of the same radicle.

It is clear therefore that the conception involved in the definition of metamerism given in Watts' *Formes*, and in the first edition of this dictionary, is scarcely in conformity with the use of the term by Berzelius, indeed, in 1840 he speaks of ethylic formate and methylic acetate as isomeric. From the example afforded by the two tin compounds, as well as from the explanation given of the nature of the change from cyanuric to cyanic acid, it is to be supposed that the compounds which he intended should be included in the category of metamerism substances were such as we should now term *typically different*, and with this conclusion the modern practice is in

VOL. III.

distinct accord, yet the modern and the original application of the term are far from being equivalent, the *meta-* in metamorphosis denoting change the conversion of the one metameride into the other being expressly referred to, it would appear, in fact, that Berzelius distinctly intended to apply the term to those compounds which are capable, in modern phraseology, of undergoing ‘isomeric change,’ and perhaps to these alone.

It was not until 1840 that Berzelius proposed to substitute the term *allotropic* (‘von *ἀλλότροπος* welches bedeutet, von ungleicher Beschaffenheit,’ *B J* 1841 inorg. sec. p. 13) for isomeric, in the cases of the existence of modifications of elementary substances. He appears, however, to have contemplated its extension to compounds, judging from the following passage —

‘Es kann dann mehr als eine Ursache von dem was wir Isomerie nennen, geben, nämlich (1) Allotropie, wenn nämlich das vorhin angeführte Beispiel von den beiden Schwefelkiesen darauf beruht, dass der eine davon S₂ und der andere S₈ enthält, (2) die ungleiche Lage der Atome in der Verbindung, und (3) kann sowohl Allotropie als ungleiche Stellung der Atome in gewissen Fällen zugleich stattfinden.’

The existence of compounds containing allotropes of one of the constituent elements is distinctly suggested here, but there is nothing to indicate in what way allotropes may be regarded as related, that Berzelius had realised that the relation might be that of polymerides would appear to follow from his reference to Frankenheim's experiments on sulphur, in which it is suggested that the different modifications of sulphur form corresponding gases, and that the dark yellow gas of sulphur, weighing thrice as much as sulphur gas should according to calculation, is not that of the modification occurring in the ordinary sulphur compounds (*v. Allotropie*, vol. 1 p. 128) the view here taken is somewhat wider than that adopted by Prof. L. Meyer in that article).

As the term *allotropic* has a general significance, implying only another condition, and involves no assumption either regarding the molecular weights of, or as to the nature of the relationship which obtains between, the allotropes, it may with great advantage be employed in place of the term isomeric used in a wide sense, this latter term being preferably restricted to those cases in which there is the very closest similarity in structure. Polymerism, metamerism, and isomerism may in fact all be regarded as varieties of allotropy, there is certainly no reason why carbon compounds should be considered apart from those of other elements, or from elementary substances.

The rational formulae which are ordinarily made use of are condensed symbolic expressions affording more or less complete information as to the characteristic chemical properties of the compounds which they represent, especially with regard to the manner in which they are formed, and in which they undergo change when submitted to the action of various agents, and equimolecular allotropes which differ either in their mode of formation or in their behaviour under similar circumstances are, as a rule, necessarily represented by different rational formulae. The formulae devised for any class of compounds, however, will vary according to the views which

G

are held as to the valencies of the constituent atoms. At present, formulae are almost invariably constructed on the hypothesis that the several units of affinity—the valencies—of a polyad atom, such as that of carbon, nitrogen, or sulphur, are of the same value and have identical functions, this conclusion being based on the fact that none of the simple derivatives of methane, ammonia, &c., exist in a greater number of modifications than the hypothesis requires. But it cannot be too positively stated that, notwithstanding the extent to which experimental investigation has been carried, we are yet but on the threshold of the temple in which the mysteries of valency are enshrined. The valency of the hydrogen atom is determined *ex hypothesi* to be unity, and when the facts generally are passed in mental review, it would seem that this conclusion is no mere hypothesis, it is not improbable also that the valencies of the atoms of at least the majority of metallic elements are invariable, but the valencies of the atoms of the non metals are apparently variable. By valency is here understood atom fixing power.

Most discussions on valency are dialectical rather than scientific, in consequence of our powerlessness at present to decide what constitutes 'a valency,' the deduction from Faraday's law of electrolysis, to which Helmholtz has directed the attention of chemists (Faraday lect., *C J Trans* 1881 p 277), that definite, as it were atomic, charges of electricity are associated with the atoms of matter—that a monad bears a single charge a dyad two, a triad three—is the only approach yet made to a theory of valency, but hitherto chemists have avoided the discussion of the subject from this point of view.

Oxygen and sulphur, nitrogen and phosphorus carbon and silicon, form gasifiable hydrides, from the composition of which we infer that the atoms of these elements are divalent, trivalent, and tetravalent, respectively, in the case of carbon and silicon there is no reason to suppose that either element ever manifests a higher valency. But both water and ammonia readily combine with other molecules the formation of such compounds from water is rarely interpreted as evidence of the possession by oxygen of the power of acting as a tetrad, but the water molecule is usually supposed to function in some occult manner as a whole, and to enter into a state of 'molecular combination' different from that of 'atomic combination' in which its constituent atoms exist. The formation of ammonium compounds, however, is more usually regarded as due to the manifestation of a higher degree of valency by the nitrogen. But there is no good reason for explaining the behaviour of oxygen in one way, and that of nitrogen in another.

The question to be decided is, whether a given element may possess two or more degrees of valency, and whether the so-called atomic and molecular forms of combination differ merely in degree and not in kind. Or, to put it in

¹ It appears to me that the term valency must at present be used in a perfectly general sense, and that we cannot restrict our attention to the consideration of gaseous compounds (*v. EQUIVALENCY*) in the case of gases, the problems are for the most part of a very simple kind, and rarely excite differences of opinion, in liquids and solids, however, present problems of great complexity

another way—is the number of atomic charges associated with a given atom invariable or variable, is it possible for an oxygen or sulphur atom, for example, to carry more than two, or for a nitrogen or phosphorus atom to carry more than three, charges? The writer has endeavoured to explain the exhibition of varying degrees of valency on the assumption that, while the number of charges which any given atom can carry is invariable, a single charge may operate in promoting the union of more than two atoms (*cf P M* January 1888), that in water, for example, the two charges of the oxygen atom are not fully engaged by those of the hydrogen atoms, and that consequently the oxygen atom is still possessed of a certain amount of *residual affinity*. It may be contended that, according to this hypothesis, a compound formed of say trimethylamine and ethyl iodide, $\text{Me}_3\text{N.IEt}$, would be an allotrope of a compound of ethyl dimethylamine and methyl iodide, $\text{EtMe}_2\text{N.MeI}$. The most careful experimental study of such compounds (*cf V Meyer a Lecco, Ber* 9, 809, Ladenburg, *Ber* 9, 561, 1634, Klinger a Claason, *A* 243, 193) has been made, however, with the result that, in the case of ammonium compounds, it is immaterial in what order or manner the radicals are introduced, and the same is true in the case of sulphine compounds—hence it is supposed that nitrogen has five, and sulphur four, affinities of equal value. But this by no means follows, as the occurrence of 'isomeric change' in such cases is in the highest degree probable—the compound abNId may alone be the stable form into which the allotropes abdNi , acdNi , bedNi , all spontaneously undergo conversion immediately on formation. There is little doubt that such 'isomeric changes' occur far more frequently than is commonly supposed, and it is most important that the possibility of 'isomeric change' should be very carefully kept in view in determining the constitution of compounds from the study of their behaviour in a limited number of interactions. As valency cannot be determined from any *a priori* considerations, and can only be deduced from the knowledge of the structure of the compounds of the elements whose valency is to be determined, it is obvious that the structure of a substance must be inferred from the widest and most careful study of all its properties. The study of the relationships of allotropic substances is in fact inseparable from that of valency, and the converse is equally true.

In the case of 'unsaturated' carbon compounds, it has been customary of late years to represent the affinities not engaged by other elements as saturating each other—thus, ethylene is formulated as $\text{H}_2\text{C.CH}_2$, acetylene as HC.CH . Thomsen's determinations of the heat of combustion of ethylene and acetylene in comparison with those of saturated hydrocarbons, as well as the general behaviour of such unsaturated compounds, may, however, be held to favour the view that the carbon atoms are possessed of free affinities, as expressed by the formulae

$\begin{array}{c} \text{H}_2\text{C} \\ \text{HC} \end{array}$ — $\begin{array}{c} \text{H}_2\text{C} \\ \text{HC} \end{array}$ —
Although the discussion of this question excited considerable attention a few years ago, it has latterly almost entirely fallen into

oblivion, but as very many of the cases of anomalous isomerism, of which an explanation is required, occur among compounds of the ethylenic type, it is one of considerable importance. The possibility of the two forms of com-

bination pictured by the expressions $\begin{array}{c} \text{H}_2\text{C} \\ \parallel \\ \text{H}_2\text{C} \end{array}$ and

$\begin{array}{c} \text{H}_2\text{C}- \\ | \\ \text{H}_2\text{C}- \end{array}$ should also be taken into account, especially in the case of ethylenic derivatives

Among the more recondite problems of valency requiring mention is that relating to the number of carbon atoms which form closed chains or rings. It is now regarded as well established that, in addition to the six atom ring of benzene, five atom rings also exist, indeed, their formation apparently takes place with peculiar readiness, the existence of both three- and four atom rings is now also generally held to be established, chiefly in consequence of the researches of W H Perkin, jun (cf *C J Trans* 1885 801, *et seq*). The hydrocarbon obtained by the action of sodium on trimethylene bromide, $\text{BrCH}_2\text{CH}_2\text{CH}_2\text{Br}$, is almost universally assumed to be the simplest compound of the kind, trimethylene

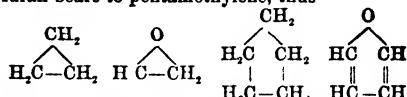

as shown by Freund, its discoverer, this hydrocarbon has the remarkable property of being readily absorbed by a solution of hydrogen iodide, forming normal propyl iodide, although it is acted on with extreme slowness by bromine. By the action of ethylenic bromide on the disodium derivative of ethylic malonate, Perkin has obtained an acid which he regards as a trimethylenedicarboxylic acid $\begin{array}{c} \text{H}_2\text{C} \\ | \\ \text{H}_2\text{C} > \text{C}(\text{COOH})_2, \end{array}$ and by employing trimethylenic bromide in place of ethylenic bromide, he has prepared what he regards as tetramethyl

enedicarboxylic acid $\begin{array}{c} \text{CH}_2-\text{CH}_2 \\ | \\ \text{CH}_2-\text{C}(\text{COOH})_2, \end{array}$ both acids

closely resemble the hydrocarbon in their behaviour with bromine and halohydrates. The easy resolution of closed carbon chains by halohydrates in this manner, however, is altogether without precedent in the case of five and six atom carbon rings, at all events, which, as a rule, cannot be split by means of halohydrates, but are frequently resolvable by bromine, their behaviour is more nearly akin to that of five atom rings, such as those of furfuran and indole, which also resist the action of bromine, but are resolvable by treatment with agents which are commonly regarded as weaker than bromine (the formation of pyridine derivatives from pyrrole and of quinoline derivatives from indole, which appears to involve the resolution at some stage of the operation of the five atom rings, is contemplated in this statement). The alternative formula for trimethylene, if it be not a closed chain hydrocarbon, is $\text{CH}_2\text{CH}_2\text{CH}_2$, which represents it as a compound in which two terminal carbon atoms are each possessed of a *single* free affinity, the possibility of the existence of such compounds has not yet been contemplated by chemists, excepting myself. It is conceivable, I think, that such a compound would be attacked by bromine with difficulty, in consequence of the two un-

satisfied carbon atoms failing to assist each other in separating the constituent atoms of the bromine molecule and the impossibility of a 'conducting chain of molecules' being formed between the carbon atoms, as bromine is a dielectric, as solutions of the halohydrates are electrolytes of low resistance, such a conducting chain might, however, be formed in their case, and the requisite electrolysis of the halohydrate molecule could thus occur. According to Thomsen, trimethylene has a *higher* heat of combustion than propylene, CH_2CHCH_2 , judging from the analogy afforded by benzenoid compounds, it is to be expected, however, that the closure of the chain involved in the formation of the three atom ring would be attended with a considerable loss of energy, and that propylene would, therefore, have the higher heat of combustion. Its behaviour with bromine certainly justifies this view. The confirmation of Thomsen's statement thus becomes of extreme importance. It is a noteworthy fact that ethylenic oxide, according to Thomsen, also has an exceptionally low heat of formation, and that this observer has proposed to represent it as a dimethylenic oxide of the formula CH_2OCH_2 . Ethylenic oxide as represented by the conventional formula bears a similar relation to trimethylene that furfuran bears to pentamethylene, thus

Thomsen's formula for ethylenic oxide is inadmissible, as it indicates a severance of the carbon atoms, if, however, the formula were written $\text{CH}_2\text{CH}_2\text{O}$, it would correspond to that given above to trimethylene, Thomsen's observations that both ethylenic oxide and trimethylene have an exceptional heat of combustion may therefore be regarded as mutually confirmatory. It is also to be noticed that the compound formed from ethylenic bromide and a sulphide is not the corresponding sulphide, but the polymeride $\text{CH}_2-\text{S}-\text{CH}_2$.

thereof $\begin{array}{c} | \\ \text{CH}_2-\text{S}-\text{CH}_2. \end{array}$ If an open chain formula

be assigned to trimethylene, Perkin's tri- and tetramethylene derivatives must also be represented by open chain formulae. Perkin has fully discussed this question, and has pointed out the improbability attaching to such formulae. The evidence does not appear to be sufficient, however, to permit of a final decision being arrived at with regard to so difficult a question.

Finally, it is necessary to refer to a problem closely akin to the two previously considered, viz. that relating to the distribution of the *spare* affinities of the carbon atoms in closed chains, of those affinities, that is to say, which are not engaged in the formation of the ring, or in retaining the hydrogen atoms. This problem is chiefly of importance in discussing the structure of benzenoid hydrocarbons and their derivatives. Of the various formulae proposed for benzene, that of Kekulé always has been, and still remains, the most popular, but it is open to the serious objection that it represents benzene as a compound containing three pairs of carbon atoms in the same condition as the pair in ethylene. Dewar's for-

mula is open to a similar objection. The prism formula of Ladenburg and the diagonal formula of Claus cannot be objected to on this ground, but are open to criticism in many other respects, and in the light of Von Baeyer's recent researches on the reduction products of terephthalic acid (cf. A 245, 103, 251, 257) these formulae are generally regarded as finally disposed of (cf. Miller, *C. S. Trans* 1887 208). A symbol proposed by the writer in February 1887 (cf. *P. M.*), and a year later also by Von Baeyer (A 245, 122), appears to be exempt from the deficiencies which characterise previous formulae, but it embodies somewhat unconventional conceptions, and therefore has not yet attracted attention. The

symbol in question  has been very happily

termed the *centric* formula by Von Baeyer, he expressly states that this formula is to be understood to indicate that 'die 6 Kohlenstoffvalenzen des Benzols sich sättigen, ohne dadurch drei Verkettungen der Kohlenstoffatome zu bewirken' (A 251, 285)—one valency of each atom is directed towards the centre of the ring, and these valencies mutually paralyse each other (A 245, 122). My own words were 'Of the twenty four affinities of the six carbon atoms twelve are engaged in the formation of the six carbon ring, while the remaining six react upon each other, acting towards a centre as it were, so that the affinity may be said to be uniformly and symmetrically distributed. I do not consider that, apart from its connexion with the other carbon atoms owing to their association in the ring, any one carbon atom is directly connected with any other atom not contiguous to it in the ring—each individual carbon exercises an influence upon each and every other carbon atom—there is an excess of affinity beyond what is required to maintain the C_6H_6 ring, but I do not consider that each carbon atom can be considered to have an affinity free'.

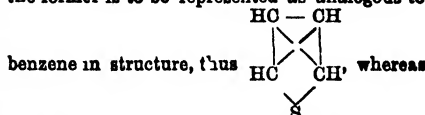

The conclusion here arrived at with regard to benzene, that no direct connexion exists between any but the contiguous carbon atoms in the ring—that para carbon atoms are not and cannot become united—may be regarded as of universal application. Von Baeyer's experiments prove, moreover, that the dihydro terephthalic acid in which an atom of hydrogen is associated with each of the para-carbon atoms to which the carboxyls are attached, unlike terephthalic acid, behaves as an unsaturated compound, forming a tetrabromide, and that it is to

be represented by the formula . From

this it follows that the type changes on conversion of the 'centric' compound into the di addition compound, and probably this is generally the case, for example, when quinol is converted into quinone

It would also follow that in the case of benzenoid compounds four of the six 'spare' affinities can not act 'centrically'. To what extent this is true in the case of other rings remains to be ascertained, from the remarkable similarity of thiophene and benzene, it would appear probable that the former is to be represented as analogous to

the analogous compounds furfuran and pyrrole more nearly resemble the unsaturated compounds in their behaviour, but this is perhaps ascribable to the influence exercised by the oxygen or imidogen.

The foregoing brief discussion will suffice to direct attention to the numerous problem comprised in the philosophy of isomerism, and to show how far from final are the conclusions as to structure which we are at present able to arrive at.

In a large and rapidly increasing number of instances, it is impossible to assign different rational formulae to compounds undoubtedly different so long as the system employed takes into account merely the nature of the radicles and the manner in which they are associated as pictured by disposing them in a single plane. If, while assuming the hydrogen atoms in a compound, such as methane—in other words the four valencies of the carbon atom—to be equal, it be supposed that the radicles introduced in place of the hydrogen atoms occupy relatively different positions in the plane, a variety of isomeric derivatives would appear to be possible, e.g. two of the form $CRRR_1R_1$, two of the form $CRRR_1R_2$, and three of the form $CRR_1R_2R_3$, $R_1R_1R_2R_3$, being different radicles. A special study of methane derivatives from this point of view has been made by Henry, but both his results and our general experience show that isomerides such as are here contemplated do not occur.

By considering the arrangement of the atoms in space, conclusions have, however, been arrived at which are far more in harmony with experience. Such a step was first taken in 1874 by Van't Hoff (*La Chimie dans l'Espace*, Rotterdam, 1875), and independently and almost simultaneously by LeBel (*Bl* [2] 22, 337, cf. *ibid* 23, 295). A German adaptation of Van't Hoff's pamphlet entitled, *Die Lagerung der Atome im Raume*, was published in 1877 by Hermann. A full account of the subject is to be found in the previous edition of this dictionary and in Miller's 'Chemistry,' vol. III.

The fundamental hypothesis of the Van't Hoff system consists, as is well known, in supposing that the carbon atom occupies the centre of a tetrahedron and that its four affinities are directed towards the four solid angles. When four different radicles are associated with the carbon atom, but only in such a case, two isomerides are possible, represented by two irregular non-superposable tetrahedra bearing to each other the relation of an object to its reflected image, and, moreover, these isomerides should be of enantiomorphous crystalline form, as

well as optically active and possessed of equal and opposite rotatory powers, as the molecules are unsymmetrical, such tetrahedra exhibiting, in relation to an axis drawn parallel to the corresponding edges, a screw shaped grouping of the four summits, turning to the right in the one form and to the left in the other. A carbon atom thus situated is termed *asymmetric*, and is represented in a formula by an italicised *C*. The hypothesis serves therefore at once to explain both the existence of isomerides which cannot be represented by formulae written in a single plane, and to account for the optical activity of certain substances. Thus in the case of tartaric acid³, which contains two asymmetric carbon atoms, but is composed of two equal groups, $(\text{COOH})(\text{HO})\text{HC}(\text{CH}(\text{OH})(\text{COOH}))$, the hypothesis indicates the existence of two optically active isomerides of equal but opposite rotatory powers, and a third inactive isomeride in which the optical effect of the one asymmetric carbon atom is balanced and neutralised by the equal opposite effect of the other, it thus accounts for the existence of dextro-, laevo-, and meso tartaric acids, racemic acid, the fourth modification, apparently, is to be regarded as a 'physical' allotrope formed by the conjunction of the two active isomerides. It would seem that it does not exist in solution. Van't Hoff has shown, in a recent much extended new edition of his pamphlet, that every prevision of the hypothesis with reference to the optical characters of isomerides has been fulfilled in the most complete manner possible by the investigations carried out in the interval since its enunciation by Le Bel and himself (cf. *Dix Années dans l'Histoire d'une Théorie*, Rotterdam, P. M. Bazendijk, 1887), this remarkable agreement of practice with theory has naturally led to the almost universal adoption of the hypothesis.

The hypothesis also provides for a greater number of isomerides in the case of compounds of the ethylenic type than is indicated if the space relationship of the radicles be omitted from consideration, if a compound of the form $\text{R}_1\text{R}_2\text{C}=\text{CR}_3\text{R}_4$ be represented by two tetrahedra joined so as to have one edge in common, it will be found that only one such figure can be constructed, if either the four radicles are identical, or if only R_1 differs from R_2 , or R_3 from R_4 , but if R_1 is different from R_2 , and R_3 is also different from R_4 , although R_1 and R_3 , R_2 and R_4 are identical, two such figures may be constructed—this is more readily rendered obvious by the adoption of the simpler plan of writing the symbols of the radicles attached to the two doubly linked carbon atoms on either side of a line representing the plane of their conjunction.

Thus the symbols $\begin{smallmatrix} a & b \\ a & b \end{smallmatrix}$ and $\begin{smallmatrix} a & b \\ b & a \end{smallmatrix}$ represent modifi-

cations in which in the one case the two similar radicles are situated symmetrically with reference to a plane at right angles to the axis of the system, and in the other are symmetrically situated with reference to the axis of the system, such modifications may therefore be termed, as Wislizenus has suggested, the *plane* and *axial* symmetric modifications. The isomerism of maleic and fumaric acids is regarded by Van't

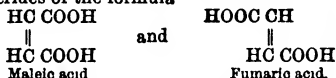

Hoff as dependent on such a difference in structure.

Such a *stereometric* mode of formulation does not afford an increased number of expressions for acetylenic derivatives, the same is true of benzenoid compounds if Kekulé's symbol be adopted (cf. Marsh, *P. M.* Nov 1888, p. 426). It may be noted, however, that the asymmetric carbon atom hypothesis is applicable to the explanation of the optical activity manifested by a variety of closed chain compounds, such as quercitol and quinic acid, which are derivatives of hexamethylene, and conine and its homologues, which are derivatives of piperidine.

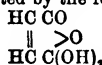

Although the Van't Hoff Le Bel hypothesis has been very generally accepted as affording a sufficient explanation of a very large number of cases of isomerism difficult to account for in accordance with the existing canons of belief, it is as yet by no means certain that it can be always so regarded, in many cases the difference between isomerides is so great that it is somewhat difficult to believe that it depends on so comparatively simple a difference in structure as the presence of one or more asymmetric carbon atoms would involve. The two isomeric tartaric acids are the veritable image the one of the other, but this is rarely the case thus hydrobenzoin differs very considerably from isohydrobenzoin, as do also mannitol and dulcitol, and to a still greater extent the acids, saccharic and mucic, formed from these latter, in all these cases the isomerism is assumed to depend on mere geometrical differences. In the case of mesotartaric acid, the intra-molecular neutralisation of one asymmetric carbon atom by the other already produces a marked effect, as evidenced by the difference in properties of this acid in comparison with either of the active modifications. It may be, therefore, that in the case of mannitol and dulcitol, and the acids formed by their oxidation, the accumulated effect of the several asymmetric carbon atoms is much greater than in the case of tartaric acid, and hence the greater difference in properties between the isomerides. Very little alteration is involved in the formation of racemic acid, and, as above pointed out, this substance appears to be a mere 'physical' allotrope, hardly a polymerde, of its active constituents, in certain cases the formation of the 'racemic form' is attended with a considerable alteration in properties—in the case of leucine and of camphoric acid, for example, their racemic forms being much less soluble and of higher melting points than their optically active constituents. In these cases there would seem to be a more intimate union than in the case of racemic acid, the marked difference between saccharic and mucic acid may be due to some such cause as this. But the isomerism of the hydrobenzoin is more difficult to explain, assuming that they are both compounds of the formula $(\text{C}_6\text{H}_5)(\text{HO})\text{HC}=\text{CCH}(\text{OH})(\text{C}_6\text{H}_5)$. Including a racemic form, four modifications of such a compound appear possible, two of which should be optically active. Neither compound is optically active, and, judging from Zincke's observations, it does not appear probable that, if the one be the meso or inactive modification corresponding to mesotartaric acid, the other is the racemic form. The assumption that the one, perhaps

isohydrobenzoin, contains the two hydroxyl-groups attached to the one carbon-atom, thus $C_6H_5 \cdot H_2C(OH)_2$, would satisfactorily account for its behaviour, but has hitherto been rejected as improbable owing to the general belief that compounds of such a character are excessively unstable. But it may be that the presence of the negative phenyl groups confers stability in such a case, much as in the case of chloral hydrate, and it is well to remember that in not a few instances of late years proof has been given of the incorrectness of views based on general considerations, as in the case of phthalic chloride, for example, and the hydroxamic acids.

Still greater difficulties occur in accepting the conclusion that the Van't Hoff hypothesis affords an explanation of the isomerism of unsaturated compounds such as maleic and fumaric acids, which, according to this view, are respectively the plane symmetric and axially symmetric isomerides of the formula

It is well known how great are the differences between these two acids, both in physical properties and in general chemical behaviour, and that maleic acid alone yields a corresponding anhydride, fumaric acid being converted into the same anhydride when dehydrated. Ostwald also has shown that the electrical conductivity of their solutions is such as to indicate that maleic acid is a weak acid akin to selenious and phosphorous acids, whereas fumaric acid is a well-marked dibasic acid (*J pr* 32, 362). Maleic acid has also a considerably greater heat of combustion than fumaric acid (Thomsen, *J pr* 40, 202). Roser has suggested that, whereas fumaric acid is a normal dicarboxylic acid, maleic acid is to be represented by the formula

This formula would afford a satisfactory explanation of the great differences observed between the two acids, and it has been strongly advocated by Anschütz (*A* 254, 168). No valid argument has yet been advanced which would prevent its adoption.

It may here be pointed out that no attention is paid in applying the Van't Hoff hypothesis to unsaturated compounds to the peculiarities which are manifest in such compounds, and which apparently must be attributed to the presence of unsaturated carbon atoms, a 'double or ethylenic bond' is represented as the precise equivalent of two single bonds, and a 'treble or acetylenic bond' as the equivalent of three single bonds, which is certainly not in accordance with facts, and especially with Thomsen's observations on the heats of combustion of unsaturated compounds.

Wislicenus has not only accepted the Van't Hoff Le Bel hypothesis in its entirety, but has in the most ingenious manner possible extended its application, and has endeavoured both to elucidate the structure of geometrically isomeric unsaturated compounds, and to explain the 'isomeric changes' which such compounds frequently exhibit (*Abhandlungen der math. phys. Klasse*

der könig Sächsischen Ges der Wissenschaften, Band xiv Leipzig, 1887).

In the case of maleic and fumaric acid—assuming that these are stereometric isomerides—as pointed out originally by Van't Hoff, the formula

assigned to the latter, as it is incapable of forming an anhydride, whereas maleic acid, being easily convertible into the anhydride, is represented by the formula

of crotonic and isocrotonic acids however, it is more difficult to find criteria on which to base a choice between the formulae

and similarly in other cases. Wislicenus considers that if a compound of the form $C_2R_1R_2R_3$, consisting of the two systems $R_1R_2C=$, and $=CR_3R_4$, be derivable from a corresponding acetylenic compound, its constitution can at once be inferred from the fact that when one pair of bonds between the carbon atoms in the acetylenic compound is severed, as the two atoms are still united by double bonds, no rotation of the systems can take place, consequently the added radicles both occupy positions on one side of the common axis of the systems. Thus the tolane dichloride melting at 143° , obtained by chlorinating tolane, is necessarily the plane symmetric modification

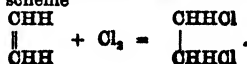

The isomeride of lower melting point (63°) must therefore be regarded as the axially symmetric compound

method appears perfectly sound, but it is based on an assumption with reference to the manner in which the carbon atoms in ethylenic and acetylenic compounds are united, which, as previously pointed out, is perhaps open to question, it also involves the conclusion that the radicles attached to the carbon atoms are incapable of changing their positions, which is also by no means a safe assumption, bearing in mind the extreme readiness with which 'isomeric changes' occur.

A method of more universal application, but involving much more complex considerations, is the following. In saturated compounds in which the carbon atoms are united by single affinities, one carbon system must be capable of rotating about another, moreover, it is to be assumed that the atoms in a molecule—even those which are not directly connected—exercise an influence on each other, and will therefore tend to condition such rotation so that radicles which have the greatest affinity are brought into the closest proximity possible. Thus, on converting ethylene into its chloride, in the first instance the change would take place in accordance with the following scheme

But, in consequence of the superior affinity of hydrogen for chlorine, such a system would be unstable, rotation would set in, and the more

stable system $\begin{array}{c} \text{CHHCl} \\ \text{CClHH} \end{array}$ would result.

To take another case, that of the conversion of tolane tetrachloride into dichloride by reduction, this compound may present three configurations, viz

It would probably chiefly consist, especially at low temperatures, of the second and third modifications, as the dissimilar radicles are most proximately situated in these, and as these two modifications would both furnish the axially symmetric dichloride on reduction, it is to be supposed that the chief product of reduction will be this dichloride, actually that melting at 63° is chiefly obtained (Blank, *A* 248, 1), and it is, therefore, to be supposed that this modification is axially symmetric—a conclusion which harmonises with that previously arrived at. To this it may be objected that our knowledge of the relative affinities of the radicles within a compound is purely hypothetical, and that it is by no means certain that dissimilar radicles would in all cases tend to influence and attract each other more than would similar radicles. Thomsen's observations on the heats of combustion of chlorine compounds, in fact, would appear to favour an opposite conclusion. But a more important argument is to be found in the fact that in cases in which the constitution may fairly be regarded as established, the relation is of the obverse order to that required if the contention of Wislicenus be correct: thus, the symmetric or para derivative of benzene always has the highest melting point, the same appears to be true of the symmetric tri- and tetra-derivatives, and, in the case of naphthalene, the axially symmetric isomeride is always that of highest melting point (*Cf C S Proc* 1888 93).

Another use which Wislicenus has made of the argument here criticised may now be mentioned. It is a well known fact that maleic acid is very readily converted into fumaric by the action of acids. Wislicenus supposes that when this conversion is effected, for example, by bromhydric acid, the double bond becomes severed, bromosuccinic acid being formed

but rotation setting in, the radicles are brought into their preferential positions, viz

HC BrCOOH , and when, by the action of the water present, this modification becomes deprived of hydrogen bromide, fumaric acid naturally results. Although in the highest degree ingenious, this conception unfortunately does not appear to be in accordance with the facts, for, as Anschütz points out (*L.* 254, 168), the conversion takes place under conditions under which the succinic derivative is stable, and there is no reason therefore to suppose that such a compound is formed at any stage of the conversion of maleic into fumaric acid, if maleic acid be formulated in the manner advocated by An-

schutz, its conversion into fumaric acid by acids is easily understood.

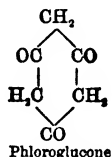

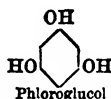

Victor Meyer's researches have led him to carry speculation even further. On submitting benzil to the action of hydroxylamine, Meyer and Goldschmidt obtained an a dihydroxime which they found was converted into a more stable β -isomeride by heating with alcohol to about 180° , a careful investigation of these compounds was subsequently made by Meyer and Auwers, but they were unable to discover any substantial difference in their chemical behaviour, and they came to the conclusion that both must be regarded as compounds of one and the same formula $\text{C}_6\text{H}_5 \cdot \text{C}(\text{N OH}) \cdot \text{C}(\text{N OH}) \cdot \text{C}_6\text{H}_5$. As the existence of two such compounds was incompatible with the assumption that carbon atoms united by single affinities are free to rotate, Meyer and Riecke (*B.* 21, 946) have put forward an hypothesis as to the nature of the carbon atom itself which serves to account for two kinds of union by single affinities, one in which rotation is impossible, the other in which it can freely take place. Having regard, however, to the readiness with which 'isomeric change' takes place, and to the extremely imperfect state of our knowledge of the exact manner in which polyad elements are held in association, there cannot be any doubt that it is premature to conclude that the benzil dihydroximes are necessarily structurally identical, the study of chemical interchanges is after all but an approximate and fallible mode of determining structure.

Hantzsch and Werner (*Ber* 23, 11) have quite recently proposed to extend the Van't Hoff conception to the nitrogen atom itself. They suppose that in some nitrogen compounds the three affinities of the nitrogen atom are directed towards three of the solid angles of an irregular tetrahedron, and that the nitrogen atom itself is located at the fourth. In the case of compounds of the form $\text{CXY} \cdot \text{NZ}$, which are comparable with carbon compounds of the form $\text{CXY} \cdot \text{CH}_3$, it is conceivable that the Z radicle may alter its position in space relatively to the radicles X and Y and thus give rise to isomerides.

Victor Meyer (*B* 23, 567) has, however, pointed out that the views of Hantzsch and Werner are in many respects in conflict with the experimental evidence. This memoir is a noteworthy contribution to the discussion of a number of the more obscure cases of isomerism. (The two papers here referred to have been published since this article was in type.)

It is here the place to refer to the numerous discussions which have taken place during late years in cases in which one set of interactions of a compound appear to be in accordance with one formula, while another set favour a different but closely related formula, which have led, in fact, to the recognition of labile or pseudo-forms capable of passing spontaneously into stable forms. For example, it has long been a question whether ethylic acetoacetate is to be represented as $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CO}_2\text{Et}$ or by the formula $\text{CH}_3 \cdot \text{C}(\text{OH}) \cdot \text{CH} \cdot \text{CO}_2\text{Et}$. A discussion of such cases has been given by Laar (*B* 18, 648, 19, 730), who proposes to term such isomerides *tautomeric*. But, as he practically himself admits, the use of such a term savours of tauto-

logy. V. Meyer subsequently brought forward a suggestion of Jacobson's to substitute *desmotropic* for tautomeric. Hantzsch and Herrmann (*B* 20, 2801), while using the term tautomerism when speaking of compounds capable of passing from the one type into the other, proposed to limit the term *desmotropic* to each of the states. As the phenomena in question are the outcome of mobility and not of fixity, the new term also appears to be particularly ill chosen, and bearing in mind the intention of Berzelius in introducing the term *metamerie* (see p 81), it would appear that this old term is a peculiarly appropriate one to use in such cases. Laar suggests that a compound which is capable of an 'alternative' behaviour actually has an alternating structure, the intra-molecular condition being such that the structure is of one kind at one moment and different at another. But, as Hantzsch and Herrmann remark, it is scarcely necessary to make such an assumption. Ethylic succinylsuccinate and its derivatives manifest the peculiarity in question in a high degree, acting sometimes as quinonic compounds and sometimes as quinols, i.e. in modes such as correspond to the presence of one or other of the two forms $\text{CO CH}(\text{CO}_2\text{Et})$ and $\text{C}(\text{OH})\text{C}(\text{CO}_2\text{Et})$. As a rule only one of the forms is stable, the other being developed in the course of the change, thus phloroglucol appears to be a true trihydroxybenzene, i.e. a phenol, but frequently it affords derivatives of 'triketohexamethylene,' which may with propriety be termed phloroglucone. Thus

It is not improbable that in those cases in which the several forms can be obtained in a definite crystalline form, the necessary stability is conferred by union of the fundamental molecules amongst themselves. The formation of such molecular complexes is rendered probable by a large number of observations, one of the most striking is that recently brought forward by Perkin in the case of orthomethoxybenzaldehyde $\text{CH}_3\text{O C}_6\text{H}_4\text{COH}$ (*C J Trans* 1889 549), which is capable of existing in two solid modifications, one unstable melting at 3° , the other stable and melting at 35.5° . A list of similar cases of what is sometimes termed *physical isomerism* is quoted by Perkin.

Having thus briefly touched on the numerous problems which the study of the different kinds of *allotropism* presents, it appears desirable finally to re-direct attention to the terminology of the subject.

The term *allotropic*, as already pointed out, has a perfectly general meaning and is therefore applicable to the phenomena generally, and may be used in all cases in which the nature of the relationship is obscure.

According to our modern conceptions, truly isomeric substances—substances composed of equal parts—are equi-molecular compounds containing identical radicals arranged in relatively

different modes, and on the principle of calling a spade a spade, bearing in mind that it was obviously the intention of Berzelius to limit the scope of the expression, the term *isomeric* should be used only with reference to such compounds. The space relationship of the radicals being the determining cause of isomerism, although it is not always requisite in order that it may become apparent to express their relationship according to stereometric canon, it is scarcely necessary to make any principal distinction between cases, such, for example, as occur among benzene derivatives and between the tartaric acids, but if it be thought desirable to call attention in some way to the finer isomerism which obtains in cases such as the latter, the term *ekisomerism*, from *εἰς*, a likeness or image, may be suggested as not inappropriate.

Typically different allotropes belonging to different classes of compounds might well be termed *heteromeric*, metameric being reserved for those heteromeric allotropes which change their type with exceptional facility in the course of chemical interchanges, but if the use of the term in this restricted sense be objected to, such allotropes might advantageously be spoken of as *isodynamic*. Allotropes belonging to the same class but consisting of different radicals—the butylic alcohols, for example—might be termed *isonomic*. It appears unnecessary to specially distinguish the physical isomerism manifest in the occurrence of several crystalline forms of different melting point. The phenomena of *pleomorphism* generally, as well as those involved in change of state from solid to liquid and gas, and the existence of allotropic forms both of the metallic and non-metallic elements, are now being more and more generally attributed to changes in molecular complexity, and if this be the case, such allotropes mostly partake of the nature of polymeric allotropes. H E A.

ISOMORPHISM (*Isos*, equal to, *μορφή*, form). In the year 1819 Mitscherlich (*A Ch* [2] 14 172) discovered that certain arsenates and phosphates of analogous constitution crystallised in the same form, subsequent investigation (*A Ch* [2] 19, 350, 24, 264, 355) led to the general conclusion that substances of analogous chemical constitution possess the same or nearly the same crystalline forms, and will under suitable conditions crystallise together in all proportions to form homogeneous mixed crystals, such substances are termed *isomorphous*. In spite of numerous attempts to widen or otherwise modify it, this definition has lasted to the present time. Owing, however, to recent researches, especially those of Groth, it will be best not to treat isomorphism as an isolated phenomenon, but as a part of that branch of physical chemistry which studies the relations between the chemical composition and crystalline form of bodies, and which from a knowledge of the constitution and chemical properties of a substance seeks to predict its system, form, and crystallographic constants. We are still very far indeed from doing anything approaching to this, for, although attempts have not been wanting—v. Schrauf (*Physikalische Mineralogie*, 1888 bd 2, 166, *Z K* 9, 265) and Barlow (*O N* 58, 8, 16)—small success has so far attended them,

and at present crystal form cannot be deduced from a knowledge of chemical constitution and properties alone, if, however, we find that in a given case certain atoms arranged in a certain definite way are accompanied by a certain definite form, we may argue that similar atoms similarly arranged will be accompanied by a similar form. This hypothesis is found to be true, and its verification has resulted in the discovery of relations between the forms of substances more or less chemically allied. These relations may be conveniently discussed under the three following heads —

I The same chemical substance possesses two or more forms—*Polymorphism*

II Bodies more or less closely related chemically have more or less analogous forms—*Morphotropy*, including *Isomorphism*

III Bodies not chemically related possess the same form—*Isogonism*

Full references, especially for the early history of the subject, will be found in the article *Isomorphism* by Arrhenius, in Fehling's *Handwörterbuch der Chemie*, 1878 vol. 1, for more recent work Fock's *Einführung in die Chemische Crystallographie*, Leipzig 1888, may be consulted, while full lists of substances considered isomorphous have been given by Topsoe, *Vidtskrift for Physik og Chemi*, 8, 5 193, 321, 9, 225 summarised by Arrhenius above. For the use of isomorphism in determining atomic weights c. ATOMIC AND MOLECULAR WEIGHTS, vol. I, p. 336

POLYMORPHISM Häuy believed that every substance possessed its own characteristic form, and, in spite of numerous observations tending to establish the chemical identity of calcite and aragonite (v. De Lisle, Klapproth, Thenard, and Stromeyer), refused to admit that the same substance could yield two distinct kinds of crystals. In the course of the work on the arsenates and phosphates which led him to announce that two different chemical compounds could possess the same or nearly the same crystalline form, Mitscherlich found that $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ gave, according to the conditions, two kinds of crystals, while his discovery in 1823 (*A. Ch.* [2] 24 264) that sulphur crystallised both in rhombic and oblique forms readily convertible the one into the other by change of temperature alone, established conclusively that the same substance could exist in two different forms, to express these phenomena Mitscherlich proposed the term *dimorphism*, and in 1828 recognised the possibility of *trimorphism*. The existence of several modifications of the same substance may be generally expressed by the terms *polymorphism* or *heteromorphism*. At the present time these terms are usually applied to compounds only, polymorphism, when exhibited by elements, being termed *allotropy* (q. v., vol. I, p. 128). The change of one dimorphic modification into another has been especially studied by Lehmann, and all known cases have been collected and discussed by him in his *Molekularphysik*, 2 vols. Leipzig, 1888 (vol. I pp. 119–219, vol. II pp. 898–415).

MORPHOTROPY From the time of Mitscherlich onwards the rapid growth of organic chemistry provided a large number of new substances for crystallographic examination, and as the existence of many cases of isomorphism among inorganic substances had been established, numerous attempts were made to introduce the same conception into organic chemistry

In general, however, these efforts were fruitless, and the researches merely resulted in the introduction of new terms and in several attempts at widening Mitscherlich's definition.

Thus Laurent, who investigated the halogen substitution and addition products of naphthalene and salts of the fatty acids, concluded that identity of system is not necessary for isomorphism. Nickles and De la Provostaye collected cases of analogous angles and introduced new terms, such as hemi isomorphism, isomorphism, and hemimorphism, to express those cases in which crystals of two substances had each a zone with nearly similar angles (v. papers by these authors, *C. R.* 11, 15, 20, 23, 26, 27, 29). Pasteur again (*C. R.* 26, 535) found analogies between the tartrates, while other workers in the same direction were Rammelsberg, Marignac, Delafosse, Sella, and Hjortdahl (*J. pr.* 94, 286). Owing to the paucity of results, such researches lost favour till Groth, in 1871 (*P.* 141, 131, *B.* 3, 449), attacked the subject from a new point of view, and set himself to investigate the changes in crystal form which take place when one or more of the hydrogen atoms of an organic molecule, such as benzene, are substituted by other atoms or groups. The relations observed between the form of the parent substance and the form of the substituted body Groth terms morphotropic relations, while he attributes the actual change of form produced by substitution to the morphotropic force of the elementary atom or group. Benzene, which crystallises in rhombic pyramids, was the first substance examined by Groth, he compared its form with the forms of as many as possible of its hydroxy-, nitro-, amido-, and haloid, substitution products, and his researches have led to the following general statement. The less the chemical character of the combination is changed by substitution the less is also the change of crystal form, which depends

1 On the specific morphotropic properties of the substituting atom or group,

2 On the chemical nature and crystalline system of the body in which substitution occurs,

3 On the relative positions of the substituting atoms or groups in the molecule.

1 Morphotropic properties of atoms and groups

(a) The metals Potassium and ammonium, when substituted for H, only change one axis, thus —

		a	b	c
Picric acid	rhombic	0.937	1	0.974
Potassium picrate	"	0.942	1	1.352

As a rule, all the alkali metals produce the same effect

(b) Substitution of OH for H in benzene derivatives only alters the crystalline form slightly, and in rhombic substances the ratios of two of the axes remain unaltered, and only the third axis is materially affected

NO_2 and NH_2 behave much like OH

		a	b	c
Benzene	rhombic	0.991	1	0.799
Resorcin	"	0.910	1	0.540
Nitrophenol 1 2	"	0.878	1	0.6007
Dinitrophenol 1 2 4	"	0.933	1	0.753
Trinitrophenol 1 2 4 6	"	0.937	1	0.974

(c) Cl, Br, and I act more energetically, but less regularly, than NO_2 . The angles of one zone, however, remain like those of the parent substance, while the system is generally altered to one of lower symmetry

Benzene	rhombic	110	$1\bar{1}0 = 96^\circ 30'$
Dichlorobenzene	oblique	"	" $98^\circ 40'$
Tetrachlorobenzene	"	"	" $96^\circ 17'$

(d) The influence of the CH_3 group is extremely variable, depending very much on the nature of the substance into which it enters. Among the substituted ammonias it is often without influence, thus, $2\text{NH}_4\text{Cl PtCl}_6$, $2\text{NH}(\text{CH}_3)_2\text{Cl PtCl}_6$, $2\text{N}(\text{CH}_3)_3\text{Cl PtCl}_6$, all crvs tallise in the cubic system

2 Influence of the nature of the parent substance. When the parent substance belongs to the cubic system, substitution has either no influence on the form, or else causes change to a system of lower symmetry. In other systems the axial ratios may alone alter, or the system itself may be changed, according to the morphotropic force of the substituting element or group. If the hydrogen atoms of like functions are replaced singly the system frequently at first changes to one of lower symmetry, but when the substitution is complete returns to the symmetry of the parent substance. The methyl substitution compounds of $2\text{NH}_4\text{Cl PtCl}_6$ illustrate this well —

$2\text{NH}_4\text{Cl PtCl}_6$	Cubic
$2\text{NH}_3(\text{CH}_3)\text{Cl PtCl}_6$	Rhombohedral
$2\text{NH}_2(\text{CH}_3)_2\text{Cl PtCl}_6$	Rhombic
$2\text{NH}(\text{CH}_3)_3\text{Cl PtCl}_6$	Cubic
$2\text{N}(\text{CH}_3)_3\text{Cl PtCl}_6$	Cubic

As an illustration of the influence of the chemical nature of the parent substance, we may quote the observation of Hintze that, contrary to the general rule, the substitution of the paraffinoid H in $(\text{C}_6\text{H}_5)_3\text{CH}$ by (OH) or Br raises the symmetry, instead of lowering it

3 Influence of position.—The relative position of the substituting atoms in the molecule has a very great influence on the form of the crystal, but we are very far from being able to connect form and constitution

As a rule the crystals of isomerides exhibit very few analogies, and in many cases none at all. In the benzene series, however, a few relations have been observed, though even here they are rare, and often more readily detected by a comparison of the isomerides with the parent substance than directly with each other. Thus a comparison of the angles given by Bodewig (*P* 158, 232) for the three dinitrobenzenes shows that certain analogies do exist, although the compounds do not crystallise in the same system, while *meta* $\text{C}_6\text{H}_4(\text{NO}_2)_2$ is related to benzene itself, as is shown in the following table —

		a	b	c
C_6H_6	rhombic	0.891	1	0.799
$\text{o C}_6\text{H}_4(\text{NO}_2)_2$	oblique	0.8112	1	0.5735 $\beta = 67^\circ 53'$
$\text{m C}_6\text{H}_4(\text{NO}_2)_2$	rhombic	0.9430	1	0.5354
$\text{p C}_6\text{H}_4(\text{NO}_2)_2$	oblique	0.9883	1	1.0432 $\beta = 87^\circ 42'$

The above examples suffice to show very clearly that the great influence exercised by position renders the discovery of the morphotropic properties of an element or group very difficult. Thus we have stated above that the entry of the nitro- group into benzene leaves the

system and axial ratio $a:b$ unaltered, while the c axis is more or less changed. This statement we found held good for $\text{o C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$, $\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}(1\ 2\ 4)$, $\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}(1\ 2\ 4\ 6)$, and $\text{m C}_6\text{H}_4(\text{NO}_2)_2$. As soon, however, as we become acquainted with o and $\text{p C}_6\text{H}_4(\text{NO}_2)_2$, the generality of our statement disappears, and the exact morphotropic value of the NO_2 group remains still undetermined. Although we are not in a position to deduce form from a knowledge of constitution alone, we may often from the chemical analogy of two substances, the form of one of which is known, draw conclusions as to the form of the other, or, *vice versa*, knowing the form of two substances, and the constitution of one of them, we may draw conclusions as to the constitution of the other. This method has been chiefly employed in inorganic chemistry, but Friedlander (*Z K* 3 168) has made use of it in order to throw light on the constitution of the trinitrobenzene got by nitrating $\text{m C}_6\text{H}_4(\text{NO}_2)_2$. The trinitrobenzene made in this way may be either of three theoretically possible ones. It crystallises, however, in the rhombic system, and has the axial ratios $0.954\ 1\ 0.733$, and agrees accordingly with $\text{m C}_6\text{H}_4(\text{NO}_2)_3$. On the other hand it shows little or no analogy to the forms of o or $\text{p C}_6\text{H}_4(\text{NO}_2)_3$, and it is therefore probable that this substance is symmetrical trinitrobenzene $1\ 3\ 5$. A comparison of its form with that of picric acid $\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}(1\ 3\ 5\ 6)$, rhombic $0.937\ 1\ 0.974$, confirms this view.

ISOMORPHOTROPY AND ISOMORPHISM. When the products obtained by replacing the hydrogen atoms of the parent substance by two closely allied atoms or groups are compared together they are often found to crystallise in identical or nearly identical forms, such products are isomorphous, while the substituting atoms or groups are said to possess the same morphotropic force, or to be isomorphotropic. Thus, K and NH_4 are isomorphotropic, and replace the H of acids to give isomorphous salts.

The term morphotropy was first applied to cases in which an atom of H was substituted, but the conception may very conveniently be extended to include all cases of substitution whatever, thus, KBr may be regarded as derived from KCl by substituting Br by Cl, and since KCl and KBr both crystallise in the same system and possess very similar physical characters, they are isomorphous, while Cl and Br are isomorphotropic. The greater the analogies between the substituting atoms the greater is the correspondence between the forms of their compounds, i.e. the more closely isomorphous they are, but because two elements are isomorphotropic when in combination with one set of atoms or groups it does not necessarily follow that they are always isomorphotropic, for the morphotropic force of any atom is largely conditioned by the compounds in which it finds itself. Again, Kopp (*P* 53, 446) has pointed out that although it is often true that two isomorphous substances combine with a third to form two isomorphous compounds (Schröder), we cannot, as has been too frequently done, deduce the isomorphism of elements from the isomorphism of their compounds, there are few elements which cannot by such a mode of reasoning be made isomorphous. Elements are only truly isomorphous when they

actually crystallise in the same forms, if they merely combine with another element or group to form isomorphous compounds they may be spoken of as isomorphotropic in that particular class of compounds. As we have seen, the conception of morphotropy includes that of isomorphism. Now, ever since the latter term was introduced, great difficulties have been felt in defining it, and in finding tests which might authoritatively decide in any given case whether two substances were isomorphous or not. Mitscherlich's definition is vague, for we at once ask, What constitutes chemical analogy? And again, How widely may the angles of two substances differ and the substances still be considered isomorphous? The truth seems to be that no hard and fast line can be drawn between those substances which are so closely related morphotropically as to be considered undoubtedly isomorphous, and those slightly less closely related whose isomorphism is doubtful, while we may pass by imperceptible stages from truly isomorphous bodies to others to which, although they still exhibit relations, this term is as evidently inapplicable. Although it seems impossible in the present state of our knowledge to give a definition which shall distinctly mark off isomorphous bodies from those which are merely closely related morphotropically, this is not in practice attended with any very great inconvenience, for the difficulty is chiefly one of nomenclature, most cases of isomorphism are at once recognised as such, and it is only in comparatively few instances that we must hesitate.

In doubtful cases much assistance may often be obtained by a comparison of the other properties of the two substances. Besides great similarity of form, agreement in several other physical properties has been thought necessary before two substances could be considered isomorphous, and we must now notice in detail the more important of these properties, pointing out the weight which has been attached to each as a test of isomorphism.

Physical properties of isomorphous substances

(a) *Geometrical properties*. As the name itself implies, near equality of external form is the first and most essential condition for isomorphism. Absolute geometrical isomorphism, however, does not exist except in the case of substances crystallising in the cubic system, in all other systems small differences of angle occur a fact first noticed by Wollaston. These differences are seldom equally distributed, in rhombic oblique and triclinic crystals the anomalies are often confined to one zone, another zone perpendicular to the first having the same angles in both cases. Here a difficulty meets us, for we ask, How great may these differences become and the substances still remain isomorphous? Unfortunately no definite answer to this question is possible, some authors have admitted much wider differences than others, while others still have gone so far as to admit that the boundaries of the systems may be overstepped. It is perhaps best to restrict the term isomorphous to substances crystallising in the same system with nearly the same angles. It is to be noted that though all substances crystallising in the cubic system have exactly the same angles

they are not necessarily isomorphous, to be so they must be either both holohedral or must both possess the same kind of hemihedrisation, and must also agree in other properties, such as cleavage and power of forming mixed crystals.

(b) *Cleavage*. Isomorphous bodies possess as a rule the same cleavages. Variations in the relative perfection of such cleavages are, however, possible. This property is especially useful in assisting us to detect isomorphism in the cubic system.

(c) *Thermal conductivity*. Jannetaz (*C. R.* 75, 1501) has shown that certain isomorphous substances have axes of maximum and minimum conductivity of like direction and magnitude.

(d) *Coefficient of expansion*. The data are not sufficient for general conclusions to be drawn, and no simple relations have been detected at present.

(e) *Etched figures*. Since these stand in a close relation to crystalline form, Baumhauer has sought to use them as a test of isomorphism. He finds that isomorphous substances give, as a rule, the same sort of etched figures, but that they often differ in orientation.

(f) *Optical properties*. These have been specially compared by Senarmont (*A. Ch.* [3] 33, 391), Topsoe, and Christiansen (*A. Ch.* [5] 1, 5). No general law has been established, but as a rule isomorphous bodies if uniaxial have the same sign of double refraction, and if biaxial have the plane of the optic axes similarly oriented, but biaxial crystals, oblique and triclinic ones especially, exhibit frequent exceptions. Optical properties are, moreover, very sensitive to changes of temperature, which often do not influence isomorphous substances to the same degree (Arzruni, *Z. K.* 1, 165).

(g) *Specific volume*. The relations between chemical composition, S.V., and crystalline form are of special importance, since several authors have considered near equality of S.V. an essential condition for isomorphism. The first of these was Kopp (*A.* 36, 1, P. 47, 133, 52, 243, 262, 53, 446), his views may be briefly summarised as follows: (1) The condition for isomorphism is equality or near equality of S.V. The answer to the question, how widely may the S.V.'s differ and the substances remain isomorphous, is given by the empirical formula

$$D = \frac{v - v_1}{\frac{1}{2}(v + v_1)}, \text{ where } v \text{ and } v_1 \text{ are the S.V.'s of the}$$

two substances. If $D=0$ the isomorphism is perfect, but if D is greater than 33 the substances are not isomorphous, thus the value of D for the two substances ZnCO_3 and CaCO_3 , whose S.V.'s are 28.2 and 36.8 respectively, is 264, they are, therefore, isomorphous. (2) Kopp has also pointed out that the nearer are the axial ratios of a series of isomorphous bodies the nearer are their S.V.'s. This statement, though criticised by Schröder, appears to hold good, and has received the support of Tschermak (*Sts. W.* 46 [2] 603) and Schrauf (*P.* 134, 417). The former expresses the law as follows: 'The series of crystal dimensions and specific volumes is in each group of isomorphous bodies of analogous composition the same'. As an illustration he gives the series of rhombohedral carbonates.

	<i>a</i>	<i>d</i>	
ZnCO ₃	1	0.807	28.2?
MgCO ₃	1	0.812	27.9
(MgFe)CO ₃	1	0.814	29.2
FeCO ₃	1	0.819	30.2
MnCO ₃	1	0.822	31.9
CaCO ₃	1	0.854	36.8

Schröder (*P* 50, 553, 95, 441, 562, 106, 226, 107, 118) at first held views much resembling those of Kopp, but in his later papers he comes to the conclusion that the statements made above are erroneous, and expresses himself thus 'The specific volumes of isomorphous compounds differ in general quite as much from one another as the specific volumes of corresponding heteromorphous compounds' (Schröder uses the term heteromorphous as opposed to isomorphous, it is now often considered synonymous with polymorphous), and he believes that his results lead him to a new law, viz 'If two elements or groups, *A* and *B*, enter into combination with other elements or groups *C*, *D*, *E*, &c., to form the compounds *A* *C* and *B* *C*, *A* *D* and *B* *D*, *A* *E* and *B* *E*, &c., belonging to the same type and isomorphous by pairs, then the differences of the specific volumes of *A* *C* and *B* *C*, *A* *D* and *B* *D*, *A* *E* and *B* *E*, are always equal'. If, however, the pairs of compounds are not isomorphous, or if the isomorphous pairs belong to different types, the differences are as a rule unequal. Schröder terms bodies of equal *SV* *isosteric*, and the equality of the differences of analogous pairs *paralleloterism*. Adopting this nomenclature, the above law may be shortly expressed thus 'Isomorphous analogous pairs of like type are also paralleloteristic'.

Tschermak (*l.c.*) finds that, although Schröder's criticism of Kopp is unfounded, his own results support Schröder's law, which he enunciates thus 'Among isomorphous bodies a like difference of composition corresponds to a like difference of specific volume,' thus the difference *Br* - *Cl* is about equal to 6.3

<i>SV</i>	<i>SV</i>	<i>SV</i>	<i>SV</i>
NaBr 33.4	KBr 44.3	AgBr 31.8	AmBr 42.2
NaCl 27.2	KCl 37.9	AgCl 26.0	AmCl 35.2
6.2	6.4	5.8	7.0

Apparent exceptions to Schröder's law are believed by Tschermak to be due to difference of constitution in the substances compared, and he illustrates this by the following table of difference for the change of composition *K* to *Am*

<i>SV</i>	<i>SV</i>
KCl 37.9	KBr 44.3
AmCl 35.2	AmBr 42.2
2.7	2.1
<i>SV</i>	<i>SV</i>
K ₂ PtCl ₆ 134.5	K ₂ SO ₄ 65.6
Am ₂ PtCl ₆ 150.5	Am ₂ SO ₄ 74.6
16.0	9.0

We see from this table that substances of the type *M'*₂PtCl₆ cannot be directly compared with those of the type *M'*₂SO₄ or these again with *M'*₂O

Tschermak has, moreover, endeavoured to trace a connection between the varying differences shown by pairs of elements which occur

in compounds of similar constitution, and the crystal-system to which these compounds belong.

<i>Cubic</i>	<i>SV</i>	<i>Oblique</i>	<i>SV</i>
Am ₂ PtCl ₆	150.5	Am ₂ Cu(SO ₄) ₂ 6aq	218
K ₂ PtCl ₆	134.5	K ₂ Cu(SO ₄) ₂ 6aq	206
	16.0		18
Am ₂ IrCl ₆	156	Am ₂ Mg(SO ₄) ₂ 6aq	209
K ₂ IrCl ₆	138.3	K ₂ Mg(SO ₄) ₂ 6aq	196
	17.7		13
<i>Tetragonal</i>			
Am ₂ CuCl ₄ 2aq	137	Am ₂ Fe(SO ₄) ₂ 6aq	212
K ₂ CuCl ₄ 2aq	133	K ₂ Fe(SO ₄) ₂ 6aq	197
			15
<i>Rhombic</i>			
Am ₂ SO ₄	74.6	Am ₂ Zn(SO ₄) ₂ 6aq	211
K ₂ SO ₄	65.6	K ₂ Zn(SO ₄) ₂ 6aq	201
	9.0		10

Thus he finds that for the change of composition *Am*₂ to *K*₂, the difference of *SV* is greatest in the cubic system, less in the oblique, still less in the rhombic, and least in the tetragonal system.

In connexion with *SV* we may note that at or about maximum and minimum points of the atomic volume curve (*v* PERIODIC LAW) occur ductile metals crystallising in the cubic system, e.g. Na, Mg, Al, K, Fe, Co, Ni, Cu, Pd, Ag, Pt, Ir, Au, Hg, Pb.

Although isomorphism is usually accompanied by similar values for the *SV*'s, we cannot from the near equality of *SV* alone deduce the isomorphism of two substances, neither can we at the present time attach much weight to Kopp's empirical formula as a test of isomorphism, in a general way, however, his results, in common with those of Tschermak, Schröder, and Schrauf appear to hold good, owing, however, to the great discrepancies which exist between the relative densities of many of the commonest substances as given by different observers, we must be cautious in accepting conclusions often resting on doubtful data.

Special properties of isomorphous substances

(a) *Formation of layer crystals*

(b) *Formation of mixed crystals*

(a) *Layer crystals*. These are made by growing a crystal of one substance in a solution of another.

Kopp (*B* 15, 1653) considers regular growth under these circumstances the best test of isomorphism.

Thus a crystal of common alum when brought into a solution of chrome alum continues to increase regularly, again the sulphates of the type *M''*SO₄ 7aq where *M''* = Zn, Mg, Fe, Co, Ni, grow in solutions of one another.

In those cases where the forms of the two substances are the same the new particles have exactly the same orientation as those of the nucleus. Klocke (*Z* K 2, 144) has, however, brought to light differences between the phenomena of growth in such cases, and in those where a crystal grows in its own solution. Having produced etched figures on the faces of two potassium alum crystals, he grew one in its

own solution, the other in a solution of ammonia iron alum, in the first case the etched figures were rapidly filled up from the bottom, in the second very much flattened octahedra of ammonia iron alum were developed at certain points on the crystal of common alum, and perfectly parallel to it, they then increased laterally, and covered up the etched figures, which remained unaltered till the new layer reached them.

Although the power of forming overgrowths seems to be a necessary consequence of isomorphism, the property is not confined to isomorphous substances alone, and from the perfect conformity of form and orientation exhibited by isomorphous substances, such as the alums, we may pass by imperceptible stages to cases of regular orientation among substances possessing but little chemical analogy and crystallising in different systems. Thus rutile TiO_2 , tetragonal, is often found developed on the basal plane of hæmatite Fe_2O_3 , rhombohedral, in such a way that the c axis of the rutile lies in a plane of symmetry of the hæmatite.

A specially interesting and much discussed case of overgrowth is that of calcite CaCO_3 , rhombohedral $rr' = 74^\circ 55'$ and NaVO_3 , rhombohedral $rr' = 73^\circ 27'$. When a rhombohedron of CaCO_3 is placed in a solution of NaVO_3 , this substance is deposited on the former in small rhombohedra, whose morphological axis and planes of symmetry are exactly parallel to those of the CaCO_3 , these rhombohedra grow till they meet, a polysynthetic crystal being the result. Kopp accordingly made a difference between growth in this case and the regular increase of alum crystals, in the light of Klocke's work, and taking into consideration the slight difference of the angles rr' , such a distinction vanishes, and if the formation of overgrowths is a test of isomorphism, these two substances are certainly isomorphous, a view confirmed by the agreement in their other physical characters, the difference in their chemical constitution leads us rather to regard them as an example of isogonism.

Closely connected with the formation of layer crystals are Thomson's researches on supersaturated solutions (*C J* 1879 196), he has shown that supersaturated solutions of certain salts can readily be crystallised by the addition of crystals of isomorphous salts, while crystals of substances not possessing the same form, or fragments of amorphous bodies, such as glass, have no influence. Thus a supersaturated solution of MgSO_4 , 7aq is at once crystallised by ZnSO_4 , 7aq, NiSO_4 , 7aq, and also by CoSO_4 , 7aq and FeSO_4 , 7aq, whose action, however, is less rapid, on the other hand, Na_2SO_4 , 10aq, NaCl , and glass, are quite inactive. Common alum can be crystallised by iron and chrome alums, while other cubic substances, such as NaCl , FeS_2 , and Fe_2O_3 , are inactive.

This appears to be an excellent test of isomorphism as far as it goes, but it unfortunately is of very limited application.

Although at the present time the formation of layer-crystals cannot be considered a conclusive proof of isomorphism, the success or failure of attempts to obtain them may help us to determine whether two substances crystallising in the cubic system are isomorphous or not.

(A discussion of numerous cases of layer-crystallisation will be found in Lehmann's *Molekularphysik*, Bd 1 pp 393-407, v also Wackernagel, *Köstmers Archiv*, 5, 293, and especially Kopp, *B* 12, 901.)

(b) *Mixed crystals* To obtain mixed crystals solutions of two substances are mixed, or in some cases the two substances are simply melted together, and then allowed to crystallise, we thus obtain perfectly homogeneous crystals, which do not, however, contain their components in any fixed ratio.

As a rule only isomorphous substances yield mixed crystals, and their formation is usually considered the best criterion of isomorphism [Klein (*C R* 95, 781), Kopp (*B* 12, 868, 17, 1105), but v also Brugelmann (*B* 17, 2359), and especially Lehmann (*l c* Bd 1 420, 456, 461)].

Numerous researches have been undertaken with a view to the elucidation of the constitution and mode of formation of mixed crystals, while other investigators have endeavoured to trace the connexion between their physical properties and those of their components.

Growth of mixed crystals Mixed crystals are most readily formed when the two substances have nearly equal solubility, and in this case Rammelsberg (*P* 91, 321) has found that the ratio of the two salts in the mixed crystal is about the same as in the solution, mixed crystals of ZnSO_4 , 7aq and MgSO_4 , 7aq afford a case in point, if, however, as more usually happens, the solubilities differ, the first crystals always contain most of the less soluble salt, the last most of the more soluble, such salts are CuSO_4 , 5aq and MnSO_4 , 5aq Thomson (*l c*) has pointed out that in the case of the crystallisation of supersaturated solutions consisting of a mixture of two substances, the composition of the mixed crystal depends very much on the velocity of crystallisation, if this takes place suddenly the composition of the mixed crystal is much the same as that of the solution, if slowly the less soluble salt is deposited first.

The physical properties of mixed crystals

(a) *Geometrical properties* Mixed crystals belong to the same system as their components, but exhibit simpler forms, cf calcite and dolomite, and v also Rammelsberg (*l c*). In some cases the angles of mixed crystals lie between those of their components, this usually holds good for the naturally occurring mixtures of the rhombohedral carbonates, thus

Chalybite FeCO_3 ,	$rr' = 72^\circ 59'$
Pistomeste (FeMgCO_3),	$= 72^\circ 42'$
Magnesite MgCO_3 ,	$= 72^\circ 33'$

But even in this series exceptions are not wanting, and as a rule no simple relation can be detected between the angles of the mixed crystals and those of its components, thus Groth (*P* 133, 193) in the case of the permanganates and perchlorates found that the angles of the mixed crystals often lay outside those of their components.

KClO_4 , rhombic	$0.7819 \ 1.0 \ 0.6396$
$\text{K} \left\{ \begin{smallmatrix} \text{Mn} \\ \text{Cl} \end{smallmatrix} \right\} \text{O}_4$, "	$0.7797 \ 1.0 \ 0.6408$
$\text{K} \left\{ \begin{smallmatrix} \text{Mn} \\ \text{Cl} \end{smallmatrix} \right\} \text{O}_4$, "	$0.7839 \ 1.0 \ 0.6398$
KMnO_4 , "	$0.7974 \ 1.0 \ 0.6492$

In the crystal containing 1Mn 1Cl the ratio $b:c$ lies inside the limits, and the other two outside, further increase in the quantity of Mn causes the form of the mixed crystal to approach nearer to that of $KClO_4$. Similar results have been obtained by Arzruni on the alkaline earths (*B* 5 1048), Memmar on baryto coelestin (*Min Mit* 1875 59), v Lang on Am_2SO_4 and K_2SO_4 (*Sitz W* 1858 81, 85), Arzruni and Baerwald on compounds of FeS_2 and $FeAs_2$ (*Z K* 7, 337), and lastly by Miers in his investigations of proustite and pyrrargyrite (*Min Mag* 8, 37).

(b) *Optical properties*

(i) *Index of refraction* In the year 1878 Dufet (*C R* 86, 881), from an investigation of $MgSO_4 \cdot 7aq$, $NiSO_4 \cdot 7aq$, and $ZnSO_4 \cdot 7aq$, found that the connection between the chemical composition of isomorphous mixtures and their indices of refraction is one of simple proportionality, so that expressing the results graphically by taking, along two axes at right angles, ordinates proportional to the observed values of μ , and abscissae proportional to the percentage of one component in the mixture, the resulting curve is a straight line. Fock (*Z K* 4, 583) has, however, taken exception to Dufet's work, and although he finds that the changes in the values of the ordinary and extraordinary ray are proportional to the changes in composition for mixed crystals of $SrSO_4 \cdot 4aq$ and $PbSO_4 \cdot 4aq$, yet in mixtures of thallium and potassium alums, and again in mixtures of $MgSO_4 \cdot 7aq$ and $MgCrO_4 \cdot 7aq$, he could find no such law, v also Fitz and Sansoni (*Z K* 6, 67). Fock's results have in their turn been questioned by Soret (*Z K* 11, 197) and Dufet (*C R* 99, 990). The former finds that mixtures of thallium and potassium alum and also of ammonium and potassium alum satisfy the law, while the latter has shown that mixtures of $MgCrO_4 \cdot 7aq$ and $MgSO_4 \cdot 7aq$ are not sufficiently homogeneous for investigations of this kind.

Dufet's law probably holds good, but further investigation is needed before it can be considered established.

(ii) *Optic axis angle* Wyruboff (*Bull Soc Min France*, 2, 91, 170) has endeavoured to trace the connection between the angle of the optic axis and the chemical composition in the cases of mixtures of K_2SO_4 and Am_2SO_4 , and of K_2CrO_4 and K_2SO_4 . His results have been expressed graphically by Mallard (*Bull Soc Min France*, 3, 3), who finds that they give a continuous regular curve, not, however, a straight line. If the optical properties of the components are non accordant, those of the mixed crystals will be different from either, v especially Senarmont (*l c*) on mixed crystals of $KNaH_2C_2O_4 \cdot 4H_2O$ and $(NH_4)NaH_2C_2O_4 \cdot 4H_2O$ —

	Optic axis plane	1st mean line	2nd mean line
Potassium salt	010	a	b
Ammonium	100	c	d

Starting from the potassium salt and substituting with NH_4 , we observe the following changes, first the obtuse angle diminishes and more quickly for red than for violet light, then at a certain point the axes for red light coincide, while the axes for violet light still lie in 010, the red axes then begin to diverge in 100, the violet

afterwards coincide and follow the red. Wyruboff (*Z K* 18, 648), on ammonium and thallium tartrates, gives the following example —

	Optic axis plane	$2H$
Ammonium salt	δ	$42^\circ 8'$
Thallium	1 to b	$59^\circ 30'$

The mixture had always the cleavage and optic axis plane of the ammonium salt, and a crystal containing 88.7 p.c. of the thallium salt had $2H = 43^\circ 30'$.

(iii) *Circular polarisation* Bodlander (*Z K* 9, 309) investigated mixtures of lead and strontium thiosulphates, he found that the rotation varied directly with the composition.

(iv) *Angle of extinction* Max Schuster has shown that the angle of extinction of certain oblique and triclinic mixed crystals, especially the feldspars, varies directly with their chemical composition. His results have been confirmed by Mallard (*Z K* 6, 612), who has treated the subject mathematically.

(v) *Specific volume relations* The specific volumes of mixed crystals appear to depend directly on the relative proportions of their compounds. Thus Schroder states (*P* 95, 441) that

$$V(aCaCO_3 + bFeCO_3) = \frac{aV'(CaCO_3) + bV''(FeCO_3)}{a + b}$$

where V is the specific volume of the mixed crystal and V' , V'' are those of its components. These results have been confirmed by Tschermak (*l c*) thus

$BaCO_3$ (witherrite) rhombic	$V = 45.7$
$CaCO_3$ (aragonite) rhombic	33.9
$(BaCa)CO_3$	= 39.8
while alstonite rhombic	= 39.5

The specific volumes of artificial mixed crystals have been especially investigated by Retgers (*Z P C* 3, 497). He has studied with great care the mixed crystals formed by (a) K_2SO_4 and Am_2SO_4 , (b) potassium and thallium alums, he finds that the SG varies directly with the composition, and expressing his results graphically he obtains as his curve a straight line, a result similar to that obtained by Dufet for the values of μ .

Formation of mixed crystals by isodimorphous substances—Two substances, X and Y, are said to be isodimorphous if they each exist in two forms A and B, A' and B', of which A is isomorphous with A' and B with B'.

On crystallising a solution containing two isodimorphous substances two series of mixed crystals are obtained, one set having the form A, the other the form B. It often happens that the form A of one salt, X say, is stable under ordinary circumstances, while of the other salt, Y, the form B is stable, in the mixed crystals of the form A the substance X predominates, in mixed crystals of the form B, Y is present in excess. In such cases as these a continuous series of mixed crystals cannot always be obtained. Crystallisation under these conditions has been especially studied by Rammsberg (*P* 91, 321). Thus he finds that $MgSO_4 \cdot 7aq$ is rhombic and $FeSO_4 \cdot 7aq$ is oblique, from a solution containing both substances two sorts of mixed crystals are obtained, these do not, however, contain their constituents in all possible proportions, but a gap

occurs, the oblique crystals always having more than 1 atom Fe to 2-3 Mg, while the rhombic crystals always contain more than 4 Mg to 1 Fe. Another good example is afforded by BeSO_4 , 4aq tetragonal and BeSeO_4 , 4aq rhombic. The mixed crystals are tetragonal when $\text{S Se} > 7.33$ 1, and rhombic when $\text{S Se} < 4.1$ (Topsøe, *Sitz W* [2] 66, v also Schulze, *A* 125, 49, Wyrouboff, *Bull Soc Min France*, 2, 91).

Cases of crystallisation perfectly analogous to but differing from these have been studied by Rammelsberg (*l c*), thus copper sulphate usually crystallises in the triclinic system with 5aq, ferrous sulphate in the oblique system with 7aq. When solutions of copper sulphate and ferrous sulphate are mixed and allowed to crystallise, two sorts of crystals are got, both of which contain Cu and Fe, as long as the proportion Cu Fe is > 20 1 the crystals possess 5aq and are triclinic, but when there is less Cu the crystals are oblique and contain 7aq.

It is very commonly supposed, when two substances closely allied chemically crystallise in different forms but yield two kinds of mixed crystals, that these substances are isomorphous, although more than one form of each may not be known, v Fock (*Z K* 6, 160), and note the adverse criticism of Wyrouboff (*Bull Soc Min* 5, 32).

The specific volumes of isomorphous substances have been compared by Rammelsberg (*B* 19, 589), while Retgers (*l c*) has found that in those cases where isomorphous substances form mixed crystals, each series obeys the law enunciated above, viz that the relative density varies directly with the composition.

Constitution of mixed crystals—Since the beginning of the century two opposing views have been held as regards the constitution of these substances.

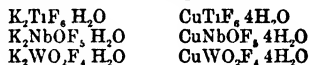

(a) According to the first or physical theory, as we may call it, the most homogeneous mixed crystal really consists of a very intimate mixture of particles of each of the components. This view, held by Haüy, and maintained by Frankenheim in opposition to Berthollet, has recently received the support of Lehmann and Retgers, the latter says that a mixed crystal is a very intimate but purely mechanical mixture of its components, and finds strong confirmation of his view in the fact that the densities, indices of refraction, &c., of mixed crystals vary directly with their composition.

(b) The supporters of the second or chemical theory maintain that molecules of each substance come together in the solution to form a complex 'liquid molecule,' while 'liquid molecules' of the same kind unite on crystallisation and form the mixed crystals. Berthollet held this view, which is perhaps more generally accepted than the other, at the present time its chief exponent is Fock, who believes that the formation of mixed crystals and double salts are phenomena of the same order.

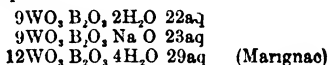

Use of mixed crystals as a test of isomorphism—As we have seen, much weight has been attached to this property by Mitscherlich, Kopp, and others, but at the present time so many instances are known of the formation of mixed crystals by substances which can not be considered isomorphous that the test

has lost much of its value (v Lehmann, *l c*) Retgers (*l c*) has proposed that only those substances should be considered isomorphous, the physical properties of whose mixed crystals vary directly with the chemical composition.

Isogonism—Speaking generally we find that if two substances are to be considered isomorphous they must satisfy the two following conditions (1) they must agree very closely in form and possess similar physical properties, (2) under suitable conditions they must be capable of forming layer and mixed crystals. In Mitscherlich's definition we find, however, a third condition, viz analogy of chemical constitution, and the question arises, How far may two substances which satisfy the two conditions above differ in chemical constitution and still be considered isomorphous? This question has received various answers, thus Scheibler (*J pr* 83, 273) has announced the isomorphism of most meta tungstates, although they do not all contain the same number of molecules of water of crystallisation, Marignac (*C R* 55, 888) considers the two following series of substances to be isomorphous—

And he also makes rhombohedral silicotungstic acid, and the acid silicotungstates of Ba and Ca isomorphous. Some other similar examples are given by Baker (*C J* 1879 760). Klein (*C R* 95, 781) believes that the following substances are isomorphous—

Klein following Marignac, amends Mitscherlich's definition thus 'Isomorphous substances have either an analogous chemical constitution or a very slightly different percentage composition, in the latter case they contain a group of common elements or elements of identical chemical function, this group making up by far the largest portion of the compound.' It seems however, hardly advisable to widen Mitscherlich's definition, indeed, it is perhaps better if possible to narrow it by defining more closely what is meant by the phrases analogous chemical composition and analogous crystalline form.

Substances, such as the double fluorides described by Marignac, are not so much isomorphous as closely related morphologically, while from them we may pass through substances exhibiting less and less of chemical analogy to those which agree in form alone, and which may therefore be considered as examples of isogonism (v Retgers, *l c*). As an instance of this we may quote the remarkable analogy noticed by Hjort dahl (*C R* 88, 584) between the crystals of tin dimethyl and diethyl chlorides and lead chloride, which all crystallise in the rhombic system, and possess the following axial ratios—

	a	b	c
Tin dimethyl chloride	0.8341	1.0	0.9407
Tin diethyl chloride	0.8386	1.0	0.9432
Lead chloride	0.8408	1.0	0.9990

At present it seems that substances which exhibit relations in form and composition may most

conveniently be divided into the following more or less arbitrary groups, between whose limits no absolute line can be drawn —

(1) Substances very closely related morphotopically, or isomorphous substances — Bodies belonging to this class possess great chemical analogy, crystallise in the same system with nearly the same forms and angles, exhibit a general agreement in the physical properties of their crystals, and often possess the same specific volume, they are, moreover, under suitable conditions capable of forming mixed and layer-crystals. Such substances are the sulphates of the group $M''SO_4 \cdot 7H_2O$ ($M'' = Fe'', Zn, Mg, Co, Ni$) and the alums.

(2) Substances closely related morphotopically — To this class belong Marignac's double fluorides, and the substances derived from hydrocarbons by substitution, from them we pass on the one hand to isomerides such as the three dinitro benzenes, which with a minimum difference of chemical constitution possess but little form analogy, and on the other hand to bodies differing but little in form, but showing less and less chemical analogy, till we reach members of the next class.

(3) Isogonous substances, differing greatly in chemical composition but nearly similar in form — To this class belong $CaCO_3$ and $NaNO_3$, and the substances described by Hjortdahl above, while all substances crystallising in the cubic system are strictly isogonous (v. Sohncke, *Entwicklung einer Theorie der Krystalstruktur*, Leipzig, 1879).

ISOPRENE v. PENTINENE

ISOPYRINE An alkaloid obtained by boiling the mashed roots of *Isopyrum thalictroides* with water, filtering, evaporating to a syrup, ppg with ammonia, and extracting with ether (Hartsen, *C* 1872, 523). White powder with bitter taste, forming an amorphous hydrochloride.

Pseudo-isopyrine After the roots have been boiled with water they still contain this alkaloid, which may be extracted with alcohol. After removing the alcohol by evaporation ammonia is added to the aqueous residue, and the ensuing pp treated with ether, whence pseudo isopyrine separates in needles. It is ppd from its solution as hydrochloride by adding very dilute HCl_{aq} and ammonium chloride (difference from isopyrine).

ISUBETIN v. FORMAMIDOXIM

ITABROMOPYROTARTARIC ACID v. BROMO

PYROTARTARIC ACID

ITACHLOROPYROTARTARIC ACID v.

CHLORO-PYROTARTARIC ACIDS

ITACONIC ACID $C_4H_4O_4$, $\pm C_4H_3(CO_2H)_2$, or $CH_2C(CO_2H)CH_2CO_2H$ (?) Mol w 130 [161°] S G 16 (Schröder, *B* 13, 1072) S 5 at 10°, 8 at 20° S (98 p.c. alcohol) 25 at 15° (Baup) R_{∞} 44.25 (in a 4.18 p.c. aqueous solution) (Kanonnikoff, *J* pr [2] 81, 348) H C 476,580 (Lougumine, *O* R 106, 1291) Heat of solution 5,923 (Gal & Werner, *B* [2] 47, 160) Heat of neutralisation 25,725 (G & W) Shown by Raoult's method to be isomeric and not polymeric with citraconic and mesaconic acids (Paternò, *B* 21, 2156).

Formation — 1 By the action of heat on citric acid, acetic acid being first formed (Baup, *A*. 19, 29, Crasso, *A* 34, 68) — 2. By

heating itamallic acid $C_8H_8O_4$ (Swarts, *Z* 1867, 649) — 3 By heating citric acid with water at 160° (Markownikoff & Purgold, *Z* 1867, 264) — 4 By heating acetic acid with water at 180° (Pebal, *A* 98, 94) — 5 By heating citraconic anhydride with water under pressure (Fitting, *A* 188, 72).

Preparation — 1 Coarsely-powdered citric acid (125 g) is distilled from shallow retorts completely filled with it as quickly as the frothing will allow, the oily distillate is separated from the water as completely as possible and left to crystallise (Meilly, *A* 171, 153, cf. Wilm, *A* 141, 28). A temperature of 160°–175° is favourable to the formation of itaconic acid, at a very high temperature it is mostly converted into citraconic anhydride — 2 Citraconic anhydride (2 vols) is heated with water (5 vols) at 150° for 7 hours, and the product poured into flat dishes and left to crystallise (Fitting, *A* 188, 72).

Properties — Trimetric octahedra (from water). Strongly acid. Sol. ether. When heated above its melting point it is resolved into citraconic anhydride and water. Ammonium itaconate gives a brown pp with $FeCl_3$, soluble in excess of $FeCl_3$, but reppd on boiling, and redissolved on cooling.

Reactions — 1 Combines with bromine, forming ita-di-bromo pyrotartaric acid (Kekulé, *A* Suppl. 1, 338, 2, 111, Cahours, *A* Ch [3] 67, 129) — 2 Chlorine forms ita-di-chloro pyrotartaric acid — 3 Heated with aqueous HBr , HCl , and HI , combination takes place with production of ita-bromo-, ita-chloro-, and ita-iodo-pyrotartaric acids. Excess of HI produces pyrotartaric acid (*Bl* [2] 4, 374) — 4 Sodium-amalgam reduces it to pyrotartaric acid (Kekulé) — 5 $HOCI$ gives chloro-itamallic acid $C_4H_3ClO_4$ — 6 Anhydrous HCl at 145° apparently forms an addition-product, which, when distilled, gives citraconic acid (Barbaglia, *B* 7, 465) — 7 Heated with aqueous K_2SO_4 , it forms a gummy salt, possibly sulphopyrotartaric acid $C_4H_3SO_4$ (Wieland, *A* 157, 34) — 8 The electrolysis of the potassium salt yields a mixture of gases, apparently containing propylene and acetylene, but not allylene $CH_2=CH_2$ (Béhal, *A* Ch [6] 16, 366, cf. Aarland, *J* pr [2] 6, 256) — 9 Cold HNO_3 gives off no CO_2 (Franchimont, *R* T C 3, 422).

Constitution — The molecular weights shown by Raoult's method to be the same as that of citraconic and of mesaconic acids. According to Aarland potassium itaconate gives a different allylene on electrolysis from that derived from the potassium salts of citraconic and mesaconic acids, this would lead to the formula $CH_2C(CO_2H)CH_2CO_2H$. Béhal, however, was unable to confirm Aarland's experiments. According to Knops (*A* 248, 228) the molecular refraction of the itaconic ethers indicates one $C=C$ group. Itaconic acid resembles mesaconic acid, but differs from citraconic acid in requiring heat to enable it to combine with HBr and with bromine. Itaconic acid reacts with aniline, but not with dimethylaniline.

Salts — KHA'' aq. lustrous laminae, v. sol. water — K_2A'' does not crystallise — $(NH_4)HA''$ tables S 80 at 12° — $(NH_4)A''$ aq. needles — $BaHA''$ aq. — BaA'' aq. (Petri, *B* 14, 1634) — $CaHA'' \cdot 2aq$ S 77 at 12° — CaA'' aq. needles. S 22 at 18° — $StrA''$ aq. — PbA'' aq. — $PbA''PbO$

(Otto, *A* 127, 181) — $\text{Ag}_2\text{A}''$ almost insol in ling water

Methyl ether $\text{Me}_2\text{A}''$ (212°) SG 15 1 1899 (Anschütz, *B* 14, 2784), Ψ 1 1241 (Knops) R_{20} 60.44 Oil Polymerises, changing to a solid in which $R_{20} = 57.7$

Ethyl ether $\text{Et}_2\text{A}''$ (229°) SG 15 1 051 (Anschütz), Ψ 1 0415 (Knops, *A* 248, 210) $R_{20} = 75.52$ Polymerises $R_{20} = 70.59$ From silver itaconate and EtI (Swarts, *Bull Acad royale Belgique* [2] 36, No 7) Formed also by passing HCl into a solution of itaconic acid in alcohol Colourless oil Changes in a few days into a viscous liquid, and ultimately into a brittle, glassy mass, which is completely decomposed on distillation

Chloride $\text{C}_4\text{H}_4(\text{COCl})_2$ (87°) at 17 mm From the anhydride and PCl_5 Colourless pungent liquid Converted by water into itaconic acid (Petrin)

Anhydride $\text{C}_4\text{H}_2(\text{C}_2\text{O}_3)_2$ [68°] (148°) at 30 mm Occurs among the products of the distillation of citric acid Prepared by the action of AcCl on itaconic acid (Anschütz, *B* 13, 1539) or on silver itaconate suspended in ether (Markownikoff, *B* 13, 1844) Trimeric prisms, $abc = 617.1 \times 455$ Sol chloroform Slowly dissolves in water with formation of itaconic acid When distilled under atmospheric pressure it changes into the isomeric citraconic anhydride

Amide $\text{C}_4\text{H}_4(\text{CONH}_2)_2$ [192°] From $\text{Me}_2\text{A}''$ and aqueous NH_3 (O Strecker, *B* 15, 1639) Small colourless crystals (from water) V e sol hot water, m sol alcohol, insol ether

Mono-anilide $\text{C}_4\text{H}_3(\text{CO}_2\text{H})(\text{CONHPh})$ or $\text{CO}_2\text{H} \text{CH} < \begin{smallmatrix} \text{CH}_2\text{NPh} \\ \text{CH}_2\text{CO} \end{smallmatrix} > (?)$ Itaconanilic acid

[189°] Formed by heating itaconic acid (5 g) with water (50 g) and aniline (3 g) to boiling for half an hour, and depositing on cooling as crystals (Michael & Palmer, *Am* 9, 200, Gotthieb, *A* 77, 265) Formed also by allowing a solution of acid aniline itaconate to stand for several days in the cold Needles (from water) Insol dilute HCl aq, sol dilute alkalis, and reprecipitated unchanged by acids — BaA'_2 (at 170°) — CuA'_2 (at 160°) — AgA'

Mono-anilide $\text{C}_4\text{H}_3(\text{CO}_2\text{H})(\text{CONHPh})$ (?) [151.5°] From itaconic anhydride and aniline (Anschütz, *B* 20, 3215, 21, 958) Not identical with the preceding

Anilide $\text{C}_4\text{H}_3(\text{CONHPh})_2$ [185°] Formed by heating aniline itaconate, or a mixture of its conic acid, with excess of aniline at 180° (Gotthieb, *A* 77, 282, O Strecker, *B* 15, 1639) Large thin plates, sol alcohol and ether, sl sol water A mixture of HNO_3 and H_2SO_4 converts it into an amorphous penta nitro- derivative (Gotthieb, *A* 85, 40)

Chloro-itaconic acid $\text{C}_4\text{H}_3\text{ClO}_4$ Formed by heating conic acid $\text{C}_4\text{H}_3\text{O}_4$ with HCl (Swarts, *J* 1873, 584) Crystalline crusts, sl sol cold water Reconverted by boiling water into conic acid

Bromo-itaconic acid $\text{C}_4\text{H}_3\text{BrO}_4$ [164°] Formed by the dry distillation of its di bromo-pyrotartaric acid $\text{C}_4\text{H}_2\text{Br}_2\text{O}_6$ (Swarts, *Bull Acad roy Belgique* [2] 88, No 1) Also by heating conic acid with HBr Its anhydride is similarly formed from its di bromo-pyrotartaric anhydride (Petrin) Crystals resembling itaconic acid (from water), v sl sol cold water, resolved by boiling

Vol. III

water or by alkaline carbonates into HBr and conic acid Reduced by tin or zinc to itaconic acid

ITAMALIC ACID v OXY-PYROTARTARIC ACID.

ITAPYRUVIC ACID $\text{C}_4\text{H}_4\text{O}_5$ Obtained, to gether with water and CO_2 , by distilling itatartaric acid at 125°–170° (Wilm, *A* 141, 37) Viscous mass, v sol water and alcohol, volatile with steam — BaA' aq (at 100°) glassy amorphous mass — PbA' , hygroscopic amorphous mass, sl sol water The silver salt is soluble, but very decomposable

ITATARTARIC ACID $\text{C}_4\text{H}_4\text{O}_5$ *Di-oxy-pyrotartaric acid* Formed by gradually adding a solution of HOCl to one of sodium itaconate (2 p c solution) at 0° in the dark, and boiling the resulting solution of chloro oxy pyrotartaric acid The acid is ppd as lead salt, which is subsequently decomposed by H_2S (Wilm, *A* 141, 28, Morawsky, *J pr* [2] 10, 68, 11, 450) Formed also by warming its di bromo pyrotartaric acid with Ag_2O (Kekulé, *A Suppl* 1, 346) Amorphous vitreous deliquescent mass V e sol water and alcohol, not volatile with steam Split up by dry distillation into CO_2 and itapyruvic acid The alkaline salts prevent the ppn of ferric and cupric salts by alkalis — CaA'' aq crystalline mass, sl sol water — BaA'' (at 100°) amorphous, v sol water, and ppd from aqueous solution by alcohol — PbA'' aq monoclinic tablets, v sl sol water — AgA'' bulky pp, sol water, but decomposed on boiling its solution

IVAIN $\text{C}_{20}\text{H}_{32}\text{O}_5$ Occurs in *Iva*, the leaves and stem of *Achillea moschata* gathered before flowering (Von Planta, *A* 155, 150) The volatile oil is first removed by distillation, and the residue is dried and extracted with alcohol, the filtrate is ppd with lead acetate, freed from lead by H_2S , and evaporated Dark yellow resinous mass, insol water, v sol alcohol The alcoholic solution has an extremely bitter taste

IVY *Hedera Helix* When ivy leaves, collected in December, are bruised, exhausted with water, and then treated with alcohol, the alcoholic extract contains a glucoside $\text{C}_{20}\text{H}_{32}\text{O}_{11}$ This may be obtained by evaporating the alcohol, extracting the residue with benzene, and then with acetone, which deposits the glucoside on cooling (Vernet, *C R* 92, 360) It forms mammillary groups of silky colourless needles with slightly sweet taste and neutral reaction. It melts at 233°, and at 22° its alcoholic solution has a levorotatory power of $[\alpha]_D = -47.5^\circ$ It is insol water, chloroform, and petroleum, sl sol acetone, benzene, and ether in the cold, but readily soluble in these liquids when hot. V sol boiling alcohol Sol cold alkalis The glucoside has no action on Fehling's solution, but on boiling with dilute H_2SO_4 a sugar is formed which crystallises by slow evaporation of its alcoholic solution in bulky transparent crystals with decided sweet taste, and reduces Fehling's solution, but is not fermented by yeast The rotatory power of a cold solution of this sugar is $[\alpha]_D = +98.6^\circ$ immediately after its preparation, but some hours afterwards it has been found to fall to $[\alpha]_D = 76.2$ Besides the sugar, there is formed in the hydrolysis of the glucoside a neutral body $\text{C}_{16}\text{H}_{24}\text{O}_5$, [278°–280°], which crys-

H

tallises in slender prismatic needles, without taste, m sol. alcohol, insol. alkalis, and dextro-rotatory $[\alpha]_D = 42.6^\circ$

IXOLITE A fossil resin found in a bed of bituminous coal at Oberhart. Fluid drops, hard-

ening to a hyacinth-red solid, which forms a yellowish powder. SG 1.008. Softens at 78° . Yields pyrocatechin on fusion with potash (Haidinger, *P* 56, 345, Weidel, *Sitz W* [2] 74, 387)

J

JABONINE $C_8H_{11}N_2$, $\epsilon\epsilon$ 

amido ethyl pyridine ($235^\circ - 240^\circ$). Formed by distilling pilocarpine or pilocarpidine with baryta (Hardy a Calmels, *Bl* [2] 48, 231). The crude product is evaporated several times with HClAq and the base set free with KOH. Colourless oil with fetid odour. Its hydro-chloride forms confusedly crystalline masses. The double salts $B'HuCl_2$, $B'AuCl_2$, B_2PtCl_4 , and $B_2H_2PtCl_4$ are all amorphous.

JABORANDI The native name for several drugs of a sudorific and salivating character, consisting of the leaves and twigs of various species of *Pilocarpus* and other trees growing in Brazil, Pernambuco, and Paraguay (Holmes, *Ph* [3] 5, 581, 641, Schelenz, *Ar Ph* [3] 7, 414, Baillon, *Ar Ph* [3] 7, 327). Jaborandi leaves contain pilocarpine (Byasson, *Ph* [3] 5, 826, Hardy, *Bl* [2] 24, 497), which readily changes to jaborine (H Meyer a Harnack, *A* 204, 67). The latter acts like atropine, and is an antidote to pilocarpine. Pilocarpine $C_8H_{11}N_2O_2$ gives with Mel a methyl iodide. Pilocarpidine $C_8H_{11}N_2O_2$ is also present in jaborandi (Harnack, *A* 238, 231). It is crystalline but extremely deliquescent. It is alkaline, and turns yellow in light. v sol. alcohol, m sol. water, sl sol. ether. Its sulphate and hydrochloride are deliquescent, its nitrate forms crystals resembling KNO_3 . Its platinum salt $B_2H_2PtCl_4$ is crystalline. It readily changes when exposed to light into a base jaboridine $C_8H_{11}N_2O_2$, which has an amorphous platinum salt. The jaborandine of Chastaing (*C R* 94, 968) obtained from pilocarpine and HNO_3 is probably jaboridine (Harnack, *A* 238, 238). The jaborandine of Parodi (*Revista farmaceutica*, 1875, 3) from *Piper reticulatum* $C_{10}H_{12}N_2O_2$ may be the same.

JABORIC ACID $C_{10}H_{12}N_2O_2$, $\epsilon\epsilon$ C_8H_9N $CMc(OH)COONMe$, $CMc(C_2H_5N)COH$. Formed, together with NMe_2 , jaborine and pilocarpidine, by rapidly heating pilocarpine to 175° , and keeping it at that temperature for half an hour. If the product be extracted with baryta water and the extract shaken with ether, the ether will contain jaborine, while pilocarpidine and jaboric acid remain in the aqueous solution. In this solution, after removing barium by CO_2 , $AgNO_3$ forms a curdy pp of C_8H_9N , O_2AgNO_3 , whence H_2S removes the silver (Hardy a Calmels, *C R* 102, 1251, *Bl* [2] 48, 225). Resinous mass, v sol. water. Not removed from its aqueous solution by ether. With alkalis it forms gummy salts, sol. water and alcohol, and not decomposed by CO_2 . Hot conc. KOHAq or boiling HClAq converts it into pilocarpidine and oxypyrindyl propionic acid C_8H_9N $CH_2CH(OH)C_2H_5$

Salts — AgA' brown powder, ppd by adding alcohol to a solution of the acid to which a limited quantity of $AgNO_3$ has been added — $AgA'AgNO_3$, curdy pp — $A',PtCl_4$, viscous pp — $A',(PtCl_4)_2$, yellow powder — A',H_2PtCl_4 , sticky pp — $A',(AuCl_3)_2$.

JABORIDINE $C_{10}H_{12}N_2O_2$. Formed by frequently evaporating pilocarpidine with acid (Harnack, *A* 238, 234). Syrup, sol. water, m sol. ether. Acts physiologically like jaborine though weaker. Its hydrochloride is syrupy, and v sol. water — $B_2H_2PtCl_4$ (dried at 100°) [$110^\circ - 120^\circ$]. Amorphous.

JABORINE C_8H_9N , $\epsilon\epsilon$ NMe_2 , $\langle CMc(C_2H_5N)COONMe \rangle$ $COONMe$, (?) Occurs in jaborandi, and in false jaborandi (the leaves of *Piper stictatum*). Prepared as described under JABORIC ACID. Brittle resin. Insol. water, v sol. ether, sol. alcohol. Dissolves in a solution of jaboric acid. Dissolves in HClAq, and is reppd by KOH as a curdy pp which readily agglomerates under warm water. Boiling conc. KOHAq converts it into pilocarpidine. Boiling HClAq does the same. Poisonous, acting like atropine.

Salts — The hydrochloride is amorphous, and v e sol. water and alcohol — B_2PtCl_4 , dirty white gelatinous pp — $B',PtCl_4$, yellowish white pp — $B'H_2PtCl_4$ — $B'(AuCl_3)_2$ (Hardy a Calmels, *C R* 102, 1251).

JALAP The roots and tubers of certain convolvulaceous plants which yield purgative resins. Official jalap consists of the tubers of *Convolvulus Schedanuss*, which contains CONVULVULIN, a strongly purgative resinous glucoside. Jalap wood or jalap stalk (Stiptes Jalapæ), the root of *C. orizabensis*, contains a different glucoside, JALAPIN (Kayser, *A* 51, 100, cf. Mayer, *A* 95, 161).

JALAPIN $C_{24}H_{34}O_{10}$ or $C_{28}H_{42}O_{12}$ [150°]. Occurs in the root stalk of *Convolvulus* (or *Ipomæa*) *orizabensis*, and forms the principal portion (soluble in ether) of the jalap resin prepared therefrom (Johnston, *P T* 1840, 342, *P M* [3] 17, 183, Kayser, *A* 51, 101, Mayer, *A* 83, 122, 95, 129, Haule, *Rep* 48, 365, Planche, *J Ph* 13, 165, 24, 169, Weppen, *N Br Arch* 87, 153, Chevallier, *J Ph* 9, 306). Occurs also in the resin in scammony root from *Convolvulus Scammonia* (Johnston, *P T* 1840, 340, Keller, *A* 104, 63, 109, 209, Spargatis, *A* 116, 289, Planche, *J Ph* 13, 165, 18, 183, Marquart, *N Br Arch* 7, 248, 10, 139).

Preparation — 1 Jalap resin is dissolved in a large quantity of alcohol, water is added until the liquid becomes slightly turbid, and the whole boiled with animal charcoal, filtered, ppd by lead acetate and a little ammonia, filtered, freed

from lead by H_2S , the alcohol distilled off, and the residue kneaded in boiling water, and the jalapin finally extracted with ether (Mayer) — 2 Finely powdered jalap resin is mixed with sand and extracted with ether, which deposits the jalapin on evaporation (Stevenson, *Ph* [3] 10, 644)

Properties — Colourless amorphous resin Softens at 123° , and melts at 150° Tasteless V sol water, v sol alcohol, ether, and chloroform, sol benzene, oil of turpentine, petroleum, and $HOAc$ Conc H_2SO_4 dissolves it slowly in the cold, acquiring in a few minutes a maroon colour, but finally becoming black With K_2CrO_4 , $KMnO_4$, $KClO_4$, or KNO_3 there is a brown colour and a smell of rancid butter, while MnO_2 gives a dark green colour (Stevenson)

Reactions — 1 Boiling dilute HCl splits it up into sugar and jalapinol — 2 Boiling aqueous alkalis convert it into jalapic acid — 3 Nitric acid forms ipomic and oxalic acids

Jalapic acid $C_{12}H_{18}O_{11}$ or $C_{12}H_{16}O_{11}$ [120°] Formed by dissolving jalapin in aqueous alkalis (W Mayer, *A* 92, 125, 95, 129, Spargatis, *A* 116, 289) Prepared by boiling jalapin with baryta-water until the solution is no longer ppd by acids, the baryta is then removed by H_2SO_4 , the excess of sulphate by lead hydrate, and the excess of lead by H_2S Jalapic acid is then deposited on evaporating Translucens, amorphous, yellowish, brittle mass Softens below 100° , and melts about 120° Has no smell, but an irritating taste and strong acid reaction. V sol water, v sol alcohol, m sol ether. In neutral solutions it is ppd by lead subacetate, but not by any other metallic salt

Reactions — 1 fuming HCl splits it up into jalapinol and glucose According to Spargatis the products of hydrolysis of jalapic acid (and jalapin) derived from scammony are jalapinic acid and glucose — 2 Boiling dilute HCl forms (a) jalapic acid, so called (Mayer) — 3 HNO_3 gives ipomic, oxalic, and isobutyric acids — 4 $KMnO_4$ gives isobutyric, oxyisobutyric, and oxalic acids (Poleck & Samelson, *C C* 1884, 813)

Salts — Jalapic acid displaces CO_2 from aqueous Na_2CO_3 — $Ba(C_{12}H_{18}O_{11})_2$ obtained on evaporating a solution of jalapic acid mixed with a slight excess of baryta-water after removing excess of baryta by CO_2 Amorphous — $Ba_2(C_{12}H_{18}O_{11})_2$ obtained by using baryta (2 pts), water (4 pts), and jalapic acid, passing CO_2 through the boiling solution, filtering and evaporating Amorphous mass [100°]

(a) - Jalapic acid, so called $C_{12}H_{18}O_{11}$, Formed, in small quantity, in the hydrolysis of jalapic acid by $HClAq$ or dilute H_2SO_4 (Mayer) On cooling it separates with the jalapinol as a soft brown amorphous mass, which is then boiled with baryta water, and the resulting solution deposits barium jalapinate on cooling When the mother liquor is concentrated silky needles of the Ba salt of (a) jalapic acid are obtained The salt is decomposed by acetic acid White flexible needles, melting below water at 80° Feebly acid in reaction Sl sol cold, m sol hot, water, v sol alcohol and ether Boiling dilute acids split it up into jalapinol and glucose HNO_3 gives ipomic acid and oxalic acid. Potash-fusion forms jalapinic acid and oxalic acid —

$Ba(C_{12}H_{18}O_{11})_2$: White needles, sol. water and alcohol

JALAPINOL $C_{12}H_{20}O_8$ [62°] Formed, together with sugar, by the hydrolysis of jalapin and of jalapic acid (W Mayer, *A* 95, 145) $C_{12}H_{18}O_{11} + 11H_2O = C_{12}H_{20}O_8 + 6C_6H_{12}O_6$ Prepared by allowing a solution of jalapic acid (2 vols) mixed with fuming $HClAq$ (1 vol), to stand for a few days, washing the crystalline product with water, and recrystallising from alcohol, with use of animal charcoal, whence it separates in cauliflower like groups of crystals Insol cold, v sol boiling water, v sol alcohol and ether Aqueous alkalis convert it into jalapinic acid $KMnO_4$ forms isobutyric acid and (by further oxidation) oxyisobutyric acid (Poleck & Samelson, *J* 1884, 1447)

JALAPINOLIC ACID $C_{12}H_{20}O_8$ [64°] Formed by treating jalapinol with aqueous KOH , ammonia, or baryta Formed also by fusing jalapin or jalapic acid with KOH (Mayer, *A* 95, 145, Spargatis, *A* 116, 306) According to Spargatis it is also produced, together with sugar, by the action of mineral acids on jalapin and jalapic acid derived from scammony Poleck and Samelson (*J* 1884, 1447) by the action of alcoholic potash on jalapinol obtained, together with isobutyl alcohol, a jalapinic acid $C_{12}H_{20}O_8$ White tufts of minute thin four sided prisms Insol water, v sol alcohol and ether Lighter than water Has an acid reaction Nitric acid oxidises it to ipomic acid and oxalic acid

Salts — $(NH_4)HA'$, cauliflower heads of minute needles — NaA' (dried at 100°) slender needles — BaA' , (dried at 120°) minute thin white needles, nearly insol cold, sl sol boiling, water, m sol boiling alcohol — CuA' , (dried at 100°) greenish blue pp formed on mixing hot aqueous solutions of sodium jalapinate and $CuSO_4$ (Spargatis) — $Cu_2A'_2(OH)_2$, (dried at 100°) Ppd by adding aqueous cupric acetate to a slightly alkaline solution of ammonium jalapinate Amorphous dark bluish-green mass — PbA' , Ppd by adding lead acetate to an alcoholic solution of jalapinic acid mixed with a little ammonia White amorphous mass — AgA' From aqueous $AgNO_3$, and alcoholic ammonium jalapinate flocculi

Ethyl ether EtA' [82.5°] From the acid (or from scammony) by saturation of the alcoholic solution with HCl , and ppg with water Flat tables

JAMBOSIN $C_{12}H_{19}NO_3$ [77°] Occurs in the bark of jambosa root (the root of *Myrtus jambosa*?), from which it may be extracted with ether (Gerrard, *Ph* [3] 14, 717) White tasteless crystals, sol cold ether, alcohol, chloroform, and hot petroleum ether Insol cold, sol boiling, water Conc H_2SO_4 gives a bright green colour changing to reddish brown Is not a glucoside. Does not form salts with bases Has no medicinal properties

JAPACONINE v ACONITINE ALKALOIDS

JAPACONITINE v ACONITINE ALKALOIDS

JAVANINE v CINCHONA BASES

JECORIN $C_{10}H_{15}N_3SE_2Na_2O_{10}$ (?) A substance obtained from liver (Drechsel, *J pr* [2] 33, 425) Occurs also in ox spleen, human brain, and horse's muscle (Baldi, *Ar Physiol* 1887, Suppl 100) Amorphous substance Hygroscopic, insoluble in dry ether, soluble in wet ether, v sol

sol alcohol Swells up in water forming a sticky mass, which separates into a clear solution and a pp The latter dissolves in much water Not p'd by boiling, p'd by NaCl Prevents p'n of cupric salts by NaOH, forming a blue solution, and on boiling a pp of Cu_2O Boiling HCl decomposes it, forming amongst other products stearic acid

JERVIC ACID An acid occurring in white hellebore root (*Veratrum album*) (Weppen, *Ar Ph* [3] 2, 101, 193), found by E Schmidt (*Ar Ph* [8] 24, 513) to be identical with chelidonic acid

JERVINE $\text{C}_{20}\text{H}_{25}\text{NO}_2$ (Wright & Luff), $\text{C}_{20}\text{H}_{25}\text{N}_2\text{O}_2$ (Tobien) or $\text{C}_{20}\text{H}_{25}\text{N}_2\text{O}_2$ (Will) [237°] (W & L) An alkaloid occurring in the rhizomes of *Veratrum album* (Weppen, *Ar Ph* [3] 2, 101, 193, Simon, *P* 41, 569, Mitchell, *Ph* [3] 4, 796, Bullock, *Ph* [3] 6, 1009, Wright & Luff, *C J* 35, 407), and of *V lobelianum* (Tobien, *Ph* [8] 8, 808) and *V viride* (Bullock, *Ph* [3] 10, 186)

Preparation—The extract obtained with alcohol containing tartaric acid is used several times to macerate fresh portions of the root, freed from alcohol by distillation, mixed with water, fractionally p'd by NaOH and taken up by ether The base first p'd is pseudojervine, and is the least soluble in ether Other fractions contain jervine, rubijervine, and veratralbine (Wright & Luff)

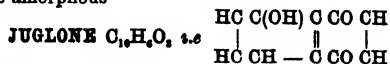

Properties—Loosely coherent crystals (containing $1\frac{1}{2}$ aq or 2aq (from alcohol) Almost insol water, sol alcohol, v sl sol ether (when pure), insol ligroin Conc H_2SO_4 forms a yellow solution changing through brown to greenish-brown Boiling alcoholic KOH has no action

Salts—The hydrochloride is crystalline, sl sol water, v sl sol HClAq (Will, *A* 35, 116) According to Tobien it gives a rose colour when warmed with nitric acid The nitrate and sulphate are sl sol water — $\text{B}^+\text{H}^+\text{Cl}^-$ (Will) — $\text{B}^+\text{H}^+\text{Ac}^-$ —The acetate is sol water

Rubijervine $\text{C}_{20}\text{H}_{25}\text{NO}_2$ [236° cor] Anhydrous crystals (from alcohol) Dissolves in conc H_2SO_4 , forming a yellow solution changing to brownish-red The sulphate is crystalline, v sol cold dilute H_2SO_4 , sl sol cold water The hydrochloride is crystalline and v sol water — $\text{B}^+\text{H}^+\text{Cl}^-$

Pseudojervine $\text{C}_{20}\text{H}_{25}\text{NO}_2$ [209°] Crystals V sl sol ether Reacts with conc H_2SO_4 in the same way as jervine Not affected by boiling alcoholic KOH — $\text{B}^+\text{H}^+\text{Cl}^-$ crystalline, v sl sol hot water, m sol dilute HClAq —The sulphate is sl sol cold, v sol hot, water — $\text{B}^+\text{H}^+\text{Ac}^-$

Veratralbine $\text{C}_{20}\text{H}_{25}\text{NO}_2$ Amorphous resinous base Conc H_2SO_4 forms a yellow solution turning crimson and exhibiting green fluorescence Alcoholic potash does not saponify it Its salts are amorphous

Oxy (a) naphthoquinone *Nucm. Regianum* [154°] Formed by the oxidation of (a) hydrojuglone which occurs in the green shell of the walnut (Vogel & Reischauer, *C C* 1858, 543, *B* 10, 1544, Phipson, *C R* 69, 1872, *C N* 52 89, Mylius, *B* 17, 2411) Formed also by allowing (1,4')-di-oxy-naphthalene to stand for 24

hours mixed with $\text{K}_2\text{Cr}_2\text{O}_7$ and dilute H_2SO_4 (Bernthsen & Semper, *B* 20, 934)

Preparation—Dry ripe walnut shells are repeatedly extracted with cold ether The etheral solution is shaken with a dilute solution of CrO_3 (10 pts $\text{K}_2\text{Cr}_2\text{O}_7$ + 18 pts H_2SO_4 in 500 pts. of water) The ether is distilled off, and the residue, after removing tarry impurities by boiling with a little ether, is crystallised from a mixture of chloroform and ligroin The yield is 150 grms from 100 kilos (Bernthsen & Semper, *B* 18, 204)

Properties—Thin glistening red prisms or needles Sublimable in small quantities Somewhat volatile with steam Easily soluble in chloroform and acetic acid, sparingly in ether, ligroin, and cold alcohol, almost insol water It stains the skin brown Dissolves in dilute NaOH with a fugitive purple colour, in H_2SO_4 with a blood red colour It is decomposed by hot water or hot acids By boiling with HNO_3 it is oxidised to a di nitro oxy phthalic acid On heating with water or HCl it decomposes into insoluble amorphous bodies Its alkaline solution is oxidised by the air to oxy juglone $\text{C}_{10}\text{H}_6\text{O}_5$ With aqueous dimethylamine it gives dimethyl amidojuglone $\text{C}_{10}\text{H}_6\text{O}_4(\text{NMe}_2)_2$ and with alcoholic aniline it gives phenyl amido juglone $\text{C}_{10}\text{H}_6\text{O}_4(\text{NHPh})$ On fusion with KOH it yields m oxy benzic acid (Mylius, *B* 18, 463) Finely powdered juglone gradually added to an alkaline solution of hydrogen peroxide is oxidised to c oxy phthalic acid (B & S) Juglone and its oxim do not dye materials mordanted with metallic oxides (Kostanecki, *B* 22, 1347) Juglone yields naphthalene when distilled with zinc dust Reducing agents yield (a) hydrojuglone

Salt— $(\text{C}_{10}\text{H}_6\text{O}_4)_2\text{Cu}$ nearly insoluble microscopic violet prisms

Acetyl derivative $\text{C}_{10}\text{H}_6\text{O}_4(\text{OAc})$ [155°], flat yellow tables or thin prisms, sublimable in long thin plates, volatile with steam, sparingly soluble in water and cold alcohol, easily in hot alcohol, ether, benzene, chloroform, and CS_2 , yields an intense green colouration with alcoholic KOH

Mono oxim $\text{C}_{10}\text{H}_6\text{O}_4(\text{OH}) \begin{cases} \text{O} \\ \text{NOH} \end{cases}$ [187°]

Glistening red needles or thin prisms, easily soluble in alcohol and acetic acid, very slightly in water, dissolves with a blood red colour in H_2SO_4 and in dilute NaOH (Bernthsen & Semper, *B* 18, 203)

Di-oxim $\text{C}_{10}\text{H}_6\text{O}_4(\text{OH})(\text{NOH})_2$ From juglone (1 mol) and hydroxylamine hydrochloride (2 mols) at 140° (Bernthsen & Semper, *B* 19, 168) Brownish yellow needles (from HOAc) Puffs off at 225° Sl sol alcohol and acetic acid Alkali dissolve it, forming an orange solution

Phenyl-amido juglone $\text{C}_{10}\text{H}_6\text{O}_4(\text{NHPh})$ [230°] Formed by heating an alcoholic solution of juglone and aniline (Mylius, *B* 18, 472) Red tables Sublimable V sl sol alcohol Dissolves in alkalis with a purple red colour

Di-methyl-amido-juglone $\text{C}_{10}\text{H}_6\text{O}_4(\text{NMe}_2)_2$ [150°] Formed by dissolving juglone in dimethylamine solution (Mylius, *B* 18, 464) Brownish-violet tables Soluble in benzene, chloroform, and CS_2 , sparingly in alcohol, ether, and acetic acid, insoluble in water By SnCl_4 it

is reduced to dimethylamido hydrojuglone; On heating with strong HCl it splits off dimethylamine, giving oxy juglone

Oxyjuglone $C_{11}H_7O_3$, s.s.

$CH_3C(OH)C(=O)C(OH)C(=O)CH_3$

Di-oxy-naphthoquinone $C_{10}H_6O_4$

$CH_3CH=CH-C(=O)CH=CH-C(=O)CH_3$

one [c 220°] Formed by heating di methylamido juglone with HCl. Formed also by oxidation of an alkaline solution of juglone by exposure to the air. Prepared by oxidation of juglone with an alkaline solution of potassium ferricyanide, yield 50 p.c. of theory (Mylus, B 18, 466). Small yellow trimetric tables. Sparingly soluble in alcohol, ether, benzene, and CS_2 .

Salts —A'Na₂ easily soluble red needles —A'K₂ sparingly soluble red needles —A'Ag₂ —A'Cl₂ amorphous red pp

Benzoyl derivative $C_{13}H_8O_4(OBz)_2$, [170°], small yellowish white crystals, easily

soluble in benzene, sparingly in alcohol and acetic acid, insoluble in water

JUGLOXIM v OXIM of JUGLONE.

JUGLONIC ACID v DI NITRO-OXY PHTHALIC ACID

JUNIPER OIL The berries of the juniper, which are used for flavouring gin, yield on distillation an essential oil $C_{10}H_{16}$, (155°-163°) S G 25 839 (Blanchet, A 7, 165, Souberran a Capitaine, A 34, 325). The oil is levorotatory, it gives no solid bromide, but after heating the oil to 260° it is partly changed to a product boiling about 180°, and this gives cinenetetrabromide. According to Wallach (A 227, 288) it contains pinene (v TERPENES). The product of distillation of the wood of the juniper contains a sesquiterpene $C_{15}H_{24}$, which forms a hydrochloride $C_{15}H_{21}H_2Cl_2$ melting at 118° (Wallach, A 238, 82).

JUTE v CELLULOSE.

K

KACOTHELINE $C_{11}H_{12}O_4N_2$ (not $C_{11}H_{12}O_4N_2$) s.s. $C_{11}H_{12}(NO_2)_2O_4N_2$. Prepared by dissolving brucine in an excess of cold nitric acid (1, 2 S G) and warming to 50°-60° till the solution has become yellowish red, the kacotheline separates out in small crystals (cf vol 1 p 654). On oxidation with CrO_3 and H_2SO_4 it yields the same product $C_{11}H_{10}N_2O_4$, as brucine. By treatment of kacotheline, suspended in boiling HCl, with bromine water it is converted into an acid $C_{11}H_{12}N_2O_4$. This acid by further oxidation with CrO_3 and H_2SO_4 yields the above oxidation product $C_{11}H_{10}N_2O_4$. On reduction with tin and HCl it yields a base $C_{11}H_{12}(NH_2)_2N_2O_4$ (Hanssen, B 20, 452).

Base $C_{11}H_{12}N_2O_4$, s.s. $C_{11}H_{12}(NH_2)_2N_2O_4$, [232°] Formed by reduction of kacotheline with tin and HCl. Needles. Atmospheric oxidation or $FeCl_3$ produces a blue black colouration. Insoluble in water and alcohol, dissolves in aqueous NaOH with a reddish yellow colour. Its methyl iodide forms glistening plates easily soluble in water —B'H₂Cl₂ large glistening crystals (Hanssen, B 20, 453).

KAIRINE v (B 4) OXY (Py 4) METHYL-QUINOLINE TETRAHYDRIDE

Kairine A v (B 4) OXY (Py 4) ETHYL QUINOLINE TETRAHYDRIDE

KAIROCOLL $C_{11}H_{11}NO_4$, s.s.

$C_6H_5(OH) \begin{cases} CH_2CH_2 \\ | \\ N-CH_2 \end{cases}$ [66°] Long fine needles

CH_2CO_2H
Sol alcohol and ether, al sol water. Prepared by heating (B 4) oxy quinoline tetrahydride with chloro acetic acid (O Fischer, B 16, 718).

KAIROLINE is described as METHYL-QUINOLINE TETRA-HYDRIDE

Amido-kairolin v AMIDO (Py 4) METHYL-QUINOLINE TETRAHYDRIDE

Nitro-kairolin v NITRO-(Py 4)-METHYL-QUINOLINE TETRA-HYDRIDE.

KAIROLINE m CARBOXYLIC ACID v (Py 4) METHYL QUINOLINE TETRA HYDRIDE (B 3)-CARBOXYLIC ACID

KAKOSTRYCHNINE v CACOSTRYCHNINE.

KAMALA A yellow dye, used in India, contained in the seed capsules of *Mallotus phillyensis*, and occurring in commerce as a yellowish brown powder composed of minute resinous globules. It contains MALLOTOXIN (q v) (A. G. a. W. H. Perkin, jun., B 19, 3109).

KAOIRI GUM The product of a coniferous tree (*Dammara australis*) growing in New Zealand. When distilled with steam it yields a terpene $C_{10}H_{16}$, (157°-158°), S G 25 863 (Rennie, C J 39, 240, cf Thomson, A Ch [3] 9, 499; Muir, C J 27, 733). It is feebly levorotatory, and yields a small quantity of cymene when treated with PCl_5 .

KAWAIN A crystalline resin, occurring along with METHYSTICIN (q v) in Kawa kawa, the root of *Macropiper methysticum* (Gobley, J Ph. [3] 37, 19, O'Rourke, C R 50, 598, Cuzent, C R 50, 436, 52, 206, Nölting a Kopp, Monat. Scient [3] 4, 9, 20). It is not a glucoside. On oxidation it yields benzoic acid.

KELLIN A glucoside in *Ammi Visnaga* (Mustapha, C R 89, 442). Small silky needles, v sl sol cold water, sol alcohol, v sol ether. Has a bitter taste. Gives a white pp with Nessler's reagent. Emetic and narcotic.

KEPHIR v MILK

KERATIN v PROTEIDS, Appendix C

KETATES (ethers of ketones) Bodies constructed on the type $\begin{matrix} X \\ | \\ Y \end{matrix} > C < \begin{matrix} O R' \\ | \\ O R'' \end{matrix}$ (Morley a. Green, B 17, 8015). Bodies of the form $\begin{matrix} X \\ | \\ Y \end{matrix} > C < \begin{matrix} SR' \\ | \\ SR'' \end{matrix}$ or $\begin{matrix} X \\ | \\ Y \end{matrix} > C < \begin{matrix} OR' \\ | \\ SR'' \end{matrix}$ may be called thioketates.

KETINE A name given by V Meyer and Treadwell (B 14, 1150, 15, 1059, 1055) to the product of the reduction of nitroso-acetone with tin and HCl. Its di-carboxylic ether is formed

in like manner by reducing nitroso-aceto-acetic ether Ketine C_6H_5O , appears to be di-methyl-
 $CH_3N CMe CH N CMe$

pyrazine $\begin{array}{c} || \\ CH_3N CH \\ || \end{array}$ or $\begin{array}{c} || \\ CH_3N CH \\ || \end{array}$, and will be

described as such (*cf* Oecononimides, *B* 19, 2524, Japp, *C J* 51, 98) Meyer (*B* 21, 19) proposes to use the name aldine instead of pyrazine

for the group $\begin{array}{c} CH N CH \\ || \end{array}$ or $\begin{array}{c} CH N CH \\ || \end{array}$ Other

alkyl-pyrazines are formed in like manner by the reduction of the nitroso-derivatives $HO N CH CO C_nH_{2n+1}$, of ketones of the form $CH_3 CO C_nH_{2n+1}$. As ketine di carboxylic acid does not form an anhydride it has probably the

formula $\begin{array}{c} || \\ CO_2H C - N CMe \\ || \end{array}$ rather than

$\begin{array}{c} || \\ CO_2H C - N C CO_2H \\ || \end{array}$, whence the symmetrical formula

for ketine given above (Oecononimides)

KETIPIC ACID A name given to Di METHYLDIKETONE DI-CARBOXYLIC ACID, as it might perhaps be called di keto adipic acid

KETO This prefix is employed by some chemists to denote the displacement of H_2 in the group C_2H_4 by O . Thus quinone might be called di keto benzene, while aceto acetic acid would be β keto-butyric acid. The prefix 'keto' does not indicate the introduction of a new or ganic group, whereas the corresponding prefix 'aldehydo-' indicates the introduction of the group CHO , and 'carboxy' is used to denote the introduction of CO_2H . In order to avoid the confusion likely to arise from this circumstance the term 'keto' is avoided in the headings of articles in this Dictionary substances which might have such names given them are described as ketones, quinones, or oxy compounds. The prefix keto- has also been used as indicating substitution of hydrogen by the ketonic group $CO CH_3$, thus Erdmann (*B* 21, 635) terms $CH_3 CO C_6H_5 OH$ keto naphthol. In keto compounds the group $CO OH$ may often be regarded with equal propriety as $C(OH)C$, and such compounds are named in accordance with the latter formula. Thus phloroglucin may be described as tri-keto-benzene hexahydrate or as tri-oxybenzene

DI-KETO- HEPTANE *v* METHYL BUTYL DIKETONE

DI-KETO-HEXANE *v* METHYL PROPYL DIKETONE

α - β -DIKETO-HEXYLENE *v* METHYL ALLYLDIKETONE

KETO-HEXA HYDRO-BENZOIC ACID CY ANHYDRIN *v* Nitrile of Oxy ISOPHTHALIC ACID HEXAHYDRIDE

DI-KETO-HYDRINDENE *v* INDONAPHTHOQUINONE

DI-KETO-INDONAPHTHENE *v* INDONAPHTHOQUINONE

KETO-LACTONIC ACID $C_5H_6O_4$, [181°] When α -acetyl- β -ethyl-succinic ether is heated it partly breaks up into alcohol and ethyl ketolactonate, which, on saponification, gives potassium ketolactonate (*S* Young, *C J* 43, 175, *A* 216, 45). It is also formed, together with $CO_2H.CHEt.CH_2Ac$, by boiling the ether

($CO_2H.CHEt.CH_2Ac$) with dilute HCl , and may be extracted from the product by ether. The free acid crystallises from water, and is al sol cold water, m sol hot water

Salts — $BaA', 2H_2O - AgA'$

Reaction — 1 Heated with baryta the following reaction occurs $2C_5H_6O_4 + 3BaO + H_2O = 2BaCO_3 + Ba(C_5H_3O_4)_2$. The new acid, $C_5H_3O_4$, appears to be liquid, it forms a very soluble and unstable silver salt — 2 Cold baryta produces an unstable dibasic acid, $C_5H_3O_4$, by assumption of H_2O

Constitution — Ketolactonic ether is formed from $CO_2Et.CHAc.CHEt.CO_2Et$ by splitting off $HOEt$. Inasmuch as $CO_2Et.CMeAc.CHEt.CO_2Et$ does not form in the same way the ether of a crystalline acid it is probable that the H which is here displaced by methyl goes to form alcohol in the formation of the ketolactonic ether. And since ketolactonic ether appears to be a lactone it should be

$CO_2Et.C.CHEt.CO_2$,

the acid being $\begin{array}{c} CH_3C O \\ || \end{array} CO_2H.C.CHEt.CO_2$

$\begin{array}{c} CH_3C O \\ || \end{array} - -$

KETOLE Another name for INDOL (*Jackson, B* 14, 879)

KETONES The ketones, in their simplest form, contain a carbonyl group CO attached to two monad hydrocarbon radicles. If the two radicles are identical, as in acetone (dimethylketone) $CH_3.CO.CH_3$, the compound is a simple ketone, if different, as in methyl ethyl ketone $CH_3.CO.CH_2CH_3$, it is a mixed ketone

Just as the fatty acids of the series $C_nH_{2n}O_2$ may be derived from the hypothetical carbonic acid $CO(OH)_2$, by replacing one hydroxyl group by a monad hydrocarbon radicle, so the ketones may in turn be derived from the fatty acids by replacing the remaining hydroxyl group by a second radicle

$HO.CO.OH$ $CH_3.CO.OH$ $CH_3.CO.CH_3$
Carbonic acid Acetic acid Acetone

There is therefore a simple ketone derivable from each fatty acid by the introduction of a hydrocarbon radicle, identical with that which is attached to the carboxyl group of the acid, in place of its hydroxyl group

If one of the radicles in a ketone is hydrogen the resulting compound is an aldehyde

$CH_3.CO.H$ $CH_3.CO.CH_3$
Aldehyde Acetone

and owing to this similarity in constitution, the aldehydes and ketones have many reactions in common. In the case of formic acid the radicle attached to carboxyl is hydrogen, and the ketone therefore coincides with the aldehyde

$H.CO.OH$ $H.CO.H$
Formic acid Formaldehyde.

From this point of view the ketones may be regarded as homologues of formaldehyde

Compounds containing two carbonyl groups are termed *diketones*, those containing three, *triketones*

Fatty ketones

Formation. — 1 By the destructive distilla-

tion of the calcium salts, or, better still, of the barium salts, of acids of the series $C_nH_{2n}O_2$.

If a mixture of the salts of two acids is employed, a mixed ketone, containing the hydrocarbon radicles of both acids, is formed

(Williamson, *C J* 1852, '38)

If one of the salts is a formate, an aldehyde is formed, a hydrogen atom from the formate attaching itself to the carbonyl group

(Piria, *Cimento*, 3, 126, *A* 100, 104, Lumprich, *A* 97, 5-8)

In the preparation of ketones by the destructive distillation of salts it is advantageous, if the molecular weight of the ketone is high, to conduct the distillation under reduced pressure (Kraft, *B* 15, 1693)

2 By the destructive distillation of the calcium compounds of primary alcohols (Destrem, *A Ch* [5] 27, 7) In this reaction the alcoholates are converted, with evolution of olefins and hydrogen, into salts of fatty acids

and the calcium acetate is then decomposed by the heat, yielding acetone. A portion of the acetate, however, reacts with the calcium oxide, evolving methane

3 By heating a mixture of the sodium compound of an alcohol and the sodium salt of a fatty acid in a current of carbon monoxide, mixtures of higher ketones are formed, along with sodium salts of higher organic acids (Genther, *A* 202, 288) The constitution of these ketones is not known with certainty, and the process in which they are formed is not understood

4 By the action of acyl chlorides on zinc alkyls (Freund, *A* 118, 1, cf Pawlow, *A* 188, 104) The acyl chloride is added to the zinc alkyl, at first gradually, afterwards more rapidly, cooling with ice during the operation. The mixture is then decomposed with excess of water

If the mixture is allowed to stand too long before adding water, the additive compound formed in the first stage of the process reacts with a second mol of alkyl chloride, exchanging its halogen for alkyl and generating a compound which, on treatment with water, yields a tertiary alcohol

5 By the oxidation of secondary alcohols

6 By the oxidation of secondary acids of the lactic series with potassium bichromate and dilute sulphuric acid. Thus hydroxy-isobutyric acid yields acetone

7 Certain ketonic acids part with carbon dioxide, forming ketones. Thus decomposition takes place very readily in the case of the β -ketonic acids. Thus when ethylic acetoacetate is warmed with a caustic alkali it is

hydrolysed, and the liberated acid splits off carbon dioxide, thus

8 Alcohols containing a hydroxyl-group attached to a doubly-linked carbon-atom do not appear to be capable of existing in the free state, and change, at the moment of their formation, into either aldehydes or ketones, the former transformation occurring when the hydroxyl group is situated at the end of, the latter when it is within, the chain

(Erlenmeyer, *B* 13, 809, 14, 320)

9 When secondary or secondary tertiary glycols are treated with dehydrating agents, such as phosphorus pentoxide or zinc chloride, they part with water, forming ketones. Probably an unsaturated alcohol is first produced, and this changes, at the moment of its formation, into a ketone (v preceding paragraph).

Primary glycols, when thus treated, yield aldehydes. Tertiary glycols (pinacones) are dehydrated even by boiling with dilute sulphuric acid, forming ketones, the reaction being accompanied in this case by the migration of an alkyl group

Pinacone

Pinacol

10 When the homologues of acetylene are passed into a solution of mercuric chloride heated to 90°-95° they take up the elements of water, yielding ketones (Kutscherow, *B* 17, 13)

Acetylene itself yields aldehyde

11 Ketones, especially acetone, are formed in the destructive distillation of wood, sugar, citric acid, and various other organic compounds

Properties and Reactions—The lower members of the ketone series are liquids, with a peculiar ethereal odour, boiling without decomposition. The higher homologues, beginning with $C_8H_{16}O$, are crystalline solids

The ketones are isomeric with the aldehydes containing the same number of atoms of carbon. They closely resemble the aldehydes in many of their reactions, but are distinguished from them by not reducing ammoniacal silver solutions. Like the aldehydes, many of the ketones combine with the *hydrogen sulphites of the alkalis* to form crystalline double compounds. The rule given by Grimm (*A* 167, 262) that only those ketones combine with hydrogen sodium sulphite which contain the group CH_3, CO , holds very generally an exception is propione (diethyl ketone) $CO(C_2H_5)_2$, which forms a double compound, although with difficulty. These compounds are used in separating and purifying the ketones on treating the double compound with sodium carbonate the ketone is liberated. The ketones, like the aldehydes, unite with *hydrocyanic acid* to form nitriles of hydroxy-acids $(CH_3)_2CO + HCN = (CH_3)_2C(OH) CN$ (Urech, *A* 164, 268, Tiemann & Friedländer, *B* 14, 1971) and these nitriles react with ammonia, yielding nitriles of amido-acids $(CH_3)_2C(OH) CN + NH_3 = (CH_3)_2C(NH_2) CN + H_2O$ (T & F.).—In

presence of caustic potash, acetone unites with *chloroform* to form acetone-chloroform $(\text{CH}_3)_2\text{C}(\text{OH})\text{COCl}$, which when heated with water to 160° yields hydroxy-isobutyric acid and hydrochloric acid (Willgerodt, *B* 14, 2451, 16, 1585) — *Sodium amalgam*, acting on aqueous solutions of the ketones, reduces them to secondary alcohols, thus acetone is converted into isopropyl alcohol $(\text{CH}_3)_2\text{CHOH}$, $\text{CO} + \text{H}_2 = (\text{CH}_3)_2\text{CHOH}$ (Friedel, *C R* 55, 53) At the same time, a second reaction occurs in which 2 mols of the ketone are united during the process of reduction, forming a tertiary glycol, or pinacone $2(\text{CH}_3)_2\text{CO} + \text{H}_2 = (\text{CH}_3)_2\text{C}(\text{OH})\text{C}(\text{OH})(\text{CH}_3)_2$. — The ketones are less susceptible of oxidation than the aldehydes, and, unlike the latter, can never yield by oxidation an acid containing the same number of carbon atoms. They are best oxidised by boiling them with a mixture of potassium bichromate and dilute sulphuric acid. Popoff (*A* 161, 300) has formulated the following rules regarding the products formed in the oxidation of the ketones — rules to which, however, there are occasional exceptions. The ketone is broken up at a point between the carbonyl group and one of the alkyl groups, the combined carbonyl being oxidised to carboxyl, and the separated alkyl being oxidised, if primary, to a fatty acid with the same number of atoms of carbon as the alkyl itself, and if secondary, to a ketone, which may in turn be further oxidised. If a ketone contains two dissimilar alkyls, the carbonyl group will remain attached to that carbon atom which has most hydrogen combined with it, unless in the case of a tertiary alkyl or a radicle of the benzene series, when the carbonyl group will remain in combination with the non hydrogenated carbon atoms. If the two dissimilar alkyls are both primary, or both secondary, or both tertiary, the carbonyl will remain attached to the alkyl of lower molecular weight. The following equations illustrate these rules

In several cases, however, a subordinate reaction, in which the ketone is oxidised in a way the reverse of that predicted by the rule, occurs simultaneously — *Chlorine* and *bromine* give substitution compounds — *Phosphorus pentachloride* replaces the oxygen of ketones by two chlorine atoms — *Ammonia* reacts less readily with ketones than with aldehydes. With acetone it forms diacetoneamine $\text{C}_6\text{H}_{11}\text{NO}$, and triacetoneamine $\text{C}_9\text{H}_{17}\text{NO}$ — With *hydroxylamine* in aqueous solution the ketones yield the ketoximes.

The ketoximes are generally solid crystalline compounds, volatile without decomposition. Concentrated hydrochloric acid decomposes them into hydroxylamine and ketone. — In like

manner *phenylhydrazine* reacts with the ketones, eliminating water and forming ketohydrazones: $\text{CH}_3\text{COCH}_3 + \text{C}_6\text{H}_5\text{NH NH}_2$

The ketohydrazones of the fatty series are for the most part only liquids, which may be distilled under reduced pressure. Acids decompose them into phenylhydrazine and ketones (E. Fischer, *B* 16, 661) — *Nitrous acid* converts the ketones into isonitroso ketones. The reaction occurs more readily, however, with ethereal salts of nitrous acid, thus when a mixture of amyl nitrite and acetone is warmed with hydrochloric acid isonitroso acetone is formed

Sodium ethoxide may be substituted for hydrochloric acid in the foregoing reaction, but in this case the sodium compound of the isonitroso ketone is formed and must afterwards be decomposed by acetic acid (Claisen, *B* 20, 252, and 656, Claisen a. Manasse, *B* 20, 2194). The isonitroso ketones are also readily obtained by the action of nitrous acid on acetoacetic acid and its homologues

Acetoacetic acid

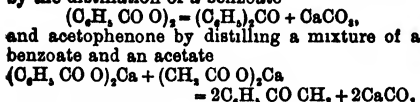

(V. Meyer a. Zublin, *B* 11, 695, Ceresole, *B* 15, 1328) — Concentrated *nitric acid* converts the ketones into dinitro paraffins, thus propione $\text{CH}_3\text{CH}_2\text{COCH}_2\text{CH}_3$ yields dinitroethane $\text{CH}_3\text{CH}(\text{NO}_2)_2$ (Chancel, *Bl* 31, 504) — The ketones react with the *mercaptans*, eliminating water and yielding 'mercaptoles' (thioketates), ethyl thiodimethylketate is formed when gaseous hydrochloric acid is passed into a mixture of acetone and mercaptan $(\text{CH}_3)_2\text{CO} + 2\text{C}_2\text{H}_5\text{SH} = (\text{CH}_3)_2\text{C}(\text{S C}_2\text{H}_5)_2 + \text{H}_2\text{O}$ (Baumann, *B* 18, 887). The mercaptoles are liquids, insoluble in water, not volatile without decomposition, stable towards alkalis and dilute acids. — Under the influence of *dehydrating agents*, such as sulphuric acid, zinc chloride, hydrochloric acid, &c., the ketones readily undergo condensation, two or more molecules combining, with elimination of water, to form more complex compounds. Thus 2 mols of acetone unite to form mesityl oxide $(\text{CH}_3)_2\text{C CH CO CH}_3$, and 3 mols to form either phorone $(\text{CH}_3)_2\text{C CH CO CH CO CH}_3$, or mesitylene (1, 3, 5 trimethylbenzene) $\text{C}_6\text{H}_2(\text{CH}_3)_3$, according as 2 or 3 mols of water are eliminated in the process.

Benzene ketones. Ketones of this class may either contain two benzene radicles directly attached to carbonyl, as in benzophenone (diphenyl ketone) $\text{C}_6\text{H}_5\text{CO C}_6\text{H}_5$, or the carbonyl group may unite a benzene radicle and a fatty radicle, as in acetophenone (phenyl methyl ketone) $\text{C}_6\text{H}_5\text{CO CH}_3$, or one or both of the benzene radicles may be attached to carbonyl by means of a fatty group, as in phenyl benzyl ketone $\text{C}_6\text{H}_5\text{CO CH}_2\text{C}_6\text{H}_5$, or di benzyl ketone $\text{C}_6\text{H}_5\text{CH}_2\text{CO CH}_2\text{C}_6\text{H}_5$.

Preparation. — Many of the methods already described for the preparation of the fatty ketones are also applicable in the case of the benzene

ketones Thus benzophenone may be obtained by the distillation of a benzoate

Again, acetophenone may be obtained by the action of benzoyl chloride on zinc methyl, but if it is desired to introduce a benzene radicle in place of the halogen of the acyl chloride the mercury compound of that radicle must be employed $\text{C}_6\text{H}_5, \text{COCl} + \text{Hg}(\text{C}_6\text{H}_5)_2$

The benzene ketones are also formed, like the fatty ketones, by the oxidation of the corresponding secondary alcohols

and of secondary glycolic acids containing benzene radicles

further, by splitting off carbon dioxide from ketonic acids of the benzene series

By shaking phenylacetylene with sulphuric acid of 75 p.c. it takes up the elements of water, yielding acetophenone

(Friedel & Baisohn, *Bt* [2] 85, 55)

The following modes of formation are peculiar to benzene ketones —

1 By the action of an acyl chloride on a benzene hydrocarbon in presence of aluminium chloride $\text{CH}_3, \text{COCl} + \text{C}_6\text{H}_6 = \text{CH}_3, \text{CO C}_6\text{H}_5 + \text{HCl}$ (Friedel & Crafts, *A Ch* [6] 1, 507) In this reaction the acid radicle always attaches itself to a benzene nucleus, and never to a fatty group. In like manner ketones containing two benzene radicles directly united to carbonyl may be prepared by acting on a benzene hydrocarbon with carbonyl chloride in presence of aluminium chloride $\text{COCl}_2 + 2\text{C}_6\text{H}_6 = \text{CO}(\text{C}_6\text{H}_5)_2 + 2\text{HCl}$

2 The last mentioned class of ketones may also be obtained by heating a mixture of a benzene carboxylic acid and a benzene hydrocarbon with phosphorus pentoxide

3 By the oxidation of hydrocarbons in which two benzene radicles are united by a methylene group

Ketone alcohols are obtained by polymerising benzene aldehydes with potassium cyanide

Ketone phenols are formed when acyl chlorides of the benzene series act on phenols in presence of zinc

The acid radicle enters the nucleus of the phenol in the para- position to the hydroxyl group

Properties and Reactions — The benzene ketones are liquids and solids, boiling without decomposition and having a pleasant aromatic odour

In most of their reactions they closely resemble the fatty ketones. Popoff's rules (*supra*) apply to the oxidation of the benzene ketones: the carbonyl group always remains attached to a benzene nucleus to which it is directly united. Like the fatty ketones, the benzene ketones react with hydroxylamine and with phenyl-hydrazine eliminating water and yielding hydroximes and hydrazones. On reduction with sodium amalgam they form secondary alcohols, but heating with hydriodic acid, or distillation with zinc dust, reduces them to the corresponding hydrocarbons

By fusion with caustic alkalis they yield a salt of a benzene acid together with a hydrocarbon

They are less subject than the fatty ketones to undergo condensation with elimination of water, and those which contain two benzene radicles directly attached to the carbonyl group do not exhibit this tendency at all

Only those benzene ketones combine with hydrogen sodium sulphite in which the carbonyl is attached to two fatty groups, one of which is methyl: thus, benzyl methyl ketone $\text{C}_6\text{H}_5, \text{CH}_2, \text{CO CH}_3$, and methyl phenylethyl ketone $\text{C}_6\text{H}_5, \text{CH}_2, \text{CH}_2, \text{CO CH}_3$, form double compounds, acetophenone $\text{C}_6\text{H}_5, \text{CO CH}_3$, does not.

Diketones The diketones contain two carbonyl groups attached to hydrocarbon radicles. If the two carbonyl groups are directly united, the compound is an α -diketone, if they are united by a carbon atom, it is a β -diketone, if by a chain of two carbon atoms, a γ -ketone, and so on.

Some of the diketones, such as benzil $\text{C}_6\text{H}_5, \text{CO CO C}_6\text{H}_5$, have been known for a considerable time, but the majority are of recent discovery. Their chief interest lies in the ease with which the two carbonyl groups may be made to condense with one or more molecules of some other substance to form closed chain compounds. In this way glyoxalines, quinolines, pyrazoles, furfurans, pyrroles, thiophenes, and similar compounds have been prepared.

α -Diketones These may be regarded as homologues of the dialdehyde glyoxal, CHO CHO . They may be obtained by the action of chlorine, or, better, of nitric acid, on a ketone alcohols

Benzoin

Benzil

(Laurent, *A Ch*. [2] 59, 402, Zinin, *A* 34, 188) By hydrolysing the isonitrosoketones by boiling them with dilute sulphuric acid

Isonitroso-ethylmethyl ketone

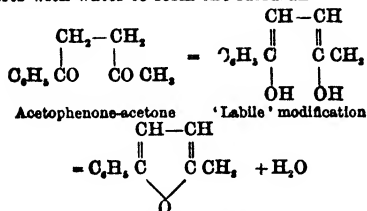

Diacetyl

(Von Pechmann, *B*. 21, 1411)

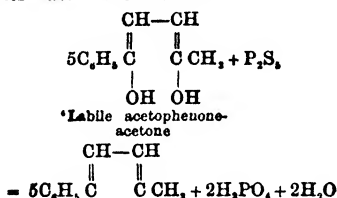

The benzenoid α -diketones react with caustic potash to form secondary glycolic acids, the two

tride, the γ -diketones are converted into furfurans. It is supposed that in this reaction the diketone first forms a 'labile' modification containing two hydroxyl groups, and that this then parts with water to form the furfuran

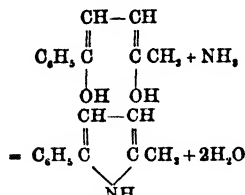

Phenylmethyl furfuran

(Paal, B 17, 2756) An unsaturated ketone isomeric with phenylmethylfurfuran is formed at the same time—*Phosphorus pentasulphide* converts γ diketones into thiophenes, whilst with ammonia they yield pyrroles, the reaction in both cases being supposed to be preceded by the above-mentioned transformation of the diketone into its 'labile' modification

Phenylmethylthiophen

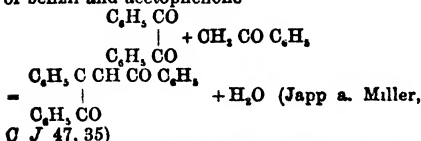

and

Phenylmethylpyrrole

(Paal, B 18, 367)

An unsaturated γ diketone, *anhydrazetophenonebenz* ($\alpha\beta$ dibenzoylstyrolene) is formed by the action of caustic potash on a mixture of benzil and acetophenone

Quinones If the two carbonyl groups of a diketone occur in a closed chain of six carbon atoms, the resulting compound belongs to the class of the quinones. This group of diketones will be treated of separately (*v* Quinones).

Triketones A triketone in which the three carbonyl groups are directly united has been obtained in the following manner (von Pechmann, B. 22, 862). Dibenzoylbromomethane

$\text{C}_6\text{H}_5\text{COCHBrCO C}_6\text{H}_5$ (prepared by the action of bromine on dibenzoylmethane, *v supra*) is converted by treatment with potassium acetate into the acetate of dibenzoylcarbinol $\text{C}_6\text{H}_5\text{COCH(OC}_2\text{H}_5\text{O)CO C}_6\text{H}_5$, which, when brominated, yields $\text{C}_6\text{H}_5\text{COCHBr(OC}_2\text{H}_5\text{O)CO C}_6\text{H}_5$. When this compound is heated above its melting-point (101.5°) it breaks up into acetyl bromide and *diphenyltriketone*

Diphenyltriketone, like some other compounds in which a carbonyl-group is situated between two electro negative groups, unites with 1 mol of water to form a hydrate, this has probably the constitution $\text{C}_6\text{H}_5\text{CO C(OH)(CO C}_6\text{H}_5\text{)CO C}_6\text{H}_5$.

The formation of another triketone, *tribenzoylmethane*, in which the three carbonyl groups are attached to the same carbon atom, has already been referred to F R J

DIKETO-PENTANE v METHYL ETHYL DIKETONE

$\alpha\beta$ DIKETO-PROPYL-BENZENE v PHENYL-METHYL DIKETONE

KINIC ACID Synonym of QUINIC ACID

KINO The dried juice, obtained from incisions in the trunk of *Pterocarpus marsupium* (Mala bar) The name has also been given to the dried juice from other trees, e.g. *Eucalyptus resinifera* (Australia) *Pterocarpus ernaceus*, and *Coccoloba uvifera* (America) Kino greatly resembles catechu, and is used in dyeing and in medicine. It occurs in small brittle opaque reddish black fragments, partly soluble in water, almost entirely soluble in alcohol, insoluble in ether. It has no odour, but a very astringent taste. Used in medicine as an astringent. It gives off pyrocatechin when distilled (Eissfeld, A 92, 101). Potash fusion forms phloroglucin and protocatechuic acid (Hlasiwetz, A 134, 122, Stenhouse, A 177, 187). Kino contains kinoin and kino red and other bodies. Kinoin has been described as a 'tannin' (Bergholz, cf Etti, B 17, 2241).

Kinoin $\text{C}_{11}\text{H}_{12}\text{O}_6$. Occurs together with kino-red, &c., in gum kino, from which it is extracted by first boiling with dilute HCl, and then extracting the solution with ether, yield 1½ p.c. (Etti, B 11, 1879). Colourless prisms. Sol cold, readily sol hot, water. On heating to 120° it gives kino red ($\text{C}_{12}\text{H}_{12}\text{O}_{11}$). On heating with HCl to 130° it is decomposed into methyl chloride, pyrocatechin, and gallic acid.

Kino red $\text{C}_{22}\text{H}_{20}\text{O}_{11}$ [160°-170°] A red resin occurring in kino and left undissolved when it is boiled with dilute HCl. It is also formed by heating kinoin. It is sol water, v sol alcohol. FeCl₃ gives a dirty green colouration. It dissolves in alkalis. It ppts a solution of gelatin. On fusion it yields a red amorphous anhydride $\text{C}_{22}\text{H}_{20}\text{O}_{10}$, which also ppts a solution of gelatin. The anhydride is also formed by heating kino-red with dilute HCl aq. Kino-red yields phenol and pyrocatechin when distilled.

KOSIN $\text{C}_{12}\text{H}_{12}\text{O}_8$ [142°] Obtained from cussor or koussor, the dried flowers of the Abyssinian koso tree (*Hagenia Abyssinica*), used by the inhabitants as a remedy again it tape worm (Flückiger a Burri, Ar Ph [3] 5, 193, Ph [3] 5, 562). The anthelmintic properties of koso seem to be due to kosin. Sulphur yellow trimetric crystals. Nearly insol. water, v sol

alcohol, ether, benzene, CS_2 , chloroform, and HOAc . Dissolves in aqueous alkalis and Na_2CO_3 , and is reprecipitated by acids. FeCl_3 colours its alcoholic solution permanently red. Conc. H_2SO_4 does not decompose it at 15° , but on warming it forms isobutyric acid and a red amorphous body $\text{C}_8\text{H}_8\text{O}_4$ (?). Potash fusion gives formic, butyric, and oxalic acids. Sodium amalgam yields a volatile oil $\text{C}_8\text{H}_8\text{O}_2$ and an amorphous yellow substance $(\text{C}_8\text{H}_8\text{O}_2)_x$.

Acetyl derivative $\text{C}_{11}\text{H}_{12}\text{Ac}_2\text{O}_4$. From kosin and Ac_2O

KOUMISS v MILK

KYANETHINE v CYANETHINE

L

LABURNINE An alkaloid said to occur along with cytosine in laburnum seeds (Husemann & Marmé, *Z* [2] 1, 161, 5, 677). Light crystalline groups of monoclinic prisms, v sol water, sl sol alcohol, nearly insol ether.

LAC A substance surrounding the eggs of *Coccus lacca* on the twigs of various trees in Bengal and Sumatra. These twigs are called stick lac. The lac is removed by melting and squeezing through canvas, when the hardened drops are known as seed lac. After bleaching by chlorine or charcoal and making into sticks it is known as shell lac or shellac. Lac is used for making sealing wax, varnishes, and a red dye called lac dye. Lac contains 68 to 88 p.c. resin (about half of which is soluble in ether), a small quantity of wax and of a red dye, and a larger quantity of a substance insoluble in alcohol. The wax [60°] contains ceryl and myricyl alcohols and their stearic, palmitic, and oleic ethers (Benedikt & Ulzer, *M* 9, 579). Shellac may be freed from wax by dissolving in boiling dilute Na_2CO_3 , filtering, and ppg with HCl . If the boiling be continued too long, liquid shellac is produced. Shellac freed from wax gives azelaic acid when oxidised by KMnO_4 (Benedikt & Ehrlich, *M* 9, 163).

Liquid shellac $\text{C}_{16}\text{H}_{12}\text{O}_4$. Formed by boiling shellac (1,000 g) with NaOH (300 g) and water (20,000 g) for 2 hours. When cold, sulphuric acid is added and the liquid shaken with ether (B & E). Thick liquid, insol water, v sol alcohol and ether. Forms salts with Pb , Ag , Zn , Ba , and Ca — $\text{C}_{16}\text{H}_{12}\text{O}_4\text{Mg}_2\text{O}_2$, amorphous, v sol water, ppd on heating, but redissolves on cooling.

Laccalic acid $\text{C}_{16}\text{H}_{12}\text{O}_4$ (?). Obtained from lac dye by treating with HClAq , filtering, boiling the residue with water, ppg the solution with lead acetate, and decomposing the pp with H_2S (R E Schmidt, *B* 20, 1285). Brownish red powder composed of minute tables (from alcohol ether), m sol alcohol, sl sol water, nearly insol ether, insol benzene. Decomposes, without previous fusion, at about 180° . Alkalis form a crimson solution which has an absorption spectrum like that of carminic acid. Baryta gives a violet pp. FeSO_4 a black pp. FeCl_3 a black colouration only. It reduces ammoniacal AgNO_3 but not Fehling's solution. Conc. HNO_3 yields picric and oxalic acids. Conc. HClAq at 180° forms a substance $\text{C}_{16}\text{H}_{12}\text{O}_{11}$. Laccalic acid dyes like carminic acid, but its solution in H_2SO_4 shows a different absorption spectrum— $\text{K}_2\text{C}_{16}\text{H}_{12}\text{O}_4$ (dried

at 100°) flocculent pp formed by adding alcoholic potash to an alcoholic solution of the salt $\text{BaC}_{16}\text{H}_{12}\text{O}_4$, brownish red pp formed by adding NH_3 and BaCl_2 .

LACMOID

Preparation—1 A mixture of resorcinol (20 pts), sodium nitrite (1 pt), and water (1 pt) is slowly heated to 110° , at which temperature a vigorous reaction sets in, the melt is then kept at 115° – 120° till it has become quite blue and the evolution of NH_3 has ceased (Traub & Hook, *B* 17, 2615)—2 By the action of H_2O_2 on ammoniacal resorcin solution (Wurster, *B* 20, 2938)—3 By fusing resorcin (15 g) with KNO_3 (18 g) (Benedikt & Juhus, *M* 5, 534).

Properties—Glistening brown powder. It is easily soluble in methyl, ethyl, and amyl alcohols, acetone, acetic acid, and phenol, less easily in ether and water, insoluble in benzene and petroleum spirit. It dissolves in strong HCl or H_2SO_4 with a blue colour. It decomposes below 200° .

Lacmoid differs from litmin, the colouring matter of litmus, in being soluble in strong alcohol. Litmin is insoluble in strong alcohol, though soluble in dilute (50 p.c.) spirit. The solution of litmin in 50 p.c. alcohol is bleached after a time, while that of lacmoid retains its colour for months. The absorption spectra of the two substances do not differ markedly (Hartley, *R. Dublin Soc* 5, 159).

LACTAM The anhydride of an amide acid $\text{R}^-(\text{NH}_2)(\text{CO}_2\text{H})$ containing the group $\text{R}^-\begin{matrix} \text{CO} \\ \diagup \\ \text{NH} \end{matrix}$

(Baeyer, *B* 15, 2102)

LACTAMIC ACID is a AMIDO PROPIONIC ACID

Di lactamic acid is a IMIDO DI PROPIONIC ACID

LACTAMIDE v Amide of LACTIC ACID

LACTARIC ACID $\text{C}_4\text{H}_6\text{O}_4$. Prepared by pressing the juice out of the mushroom (*Lactarius piperatus*) and extracting the residue with ether or boiling alcohol (Chuit, *Bl* [3] 2, 158). White leaflets (from alcohol), v sol hot alcohol, ether, CHCl_3 , CS_2 , and benzene, v sl sol cold alcohol and petroleum spirit, insol water.

Salts—**Naa'** greasy scales, decomposing at 250° —**Ka'** silvery scales, decomposing at 245° without melting—**KHa'**, silky scales. [115°]—**NH₄A'** [92°], white leaflets, decomposed by boiling water—**CaA'**, scales. When distilled it forms the ketone $(\text{C}_4\text{H}_6\text{O})_2\text{CO}$ [82°]—**BaA'**, white amorphous pp. Insol water, alcohol, and ether—**PbHa'**, [114°]. Thin transparent leaflets.

Isomerides—Lactic acid is isomeric with hydracrylic acid, and appears to be chemically identical with sarcosolactic acid (*v infra*)

In 1863 Wislicenus got from ethylene chlorhydrin and KCN, by saponifying the product, a lactic acid which formed a crystalline zinc salt ZnA', 2aq. He called it ethylene lactic acid, thought it was identical with Liebig's sarcosolactic acid (A 128, 4) Dossios (A 146, 168) said that sarcosolactic acid gave, on oxidation, malonic acid. Wislicenus held (A 167, 346) that his ethylene lactic acid was not hydracrylic acid, for by the action of HI he was unable to obtain β iodopropionic acid. He said also that his ethylene lactic acid differed from sarcosolactic, although it accompanied sarcosolactic acid in extract of meat. Erlenmeyer (A 191, 261) showed that Wislicenus's ethylene lactic acid from glycol chlorhydrin is hydracrylic acid, and could be converted by HI into β iodopropionic acid. The acid accompanying sarcosolactic acid is, according to Siegfried (B 22, 2711) the acetyl derivative of lactic acid.

Occurrence—1 Discovered by Scheele in sour milk and first recognised as a peculiar acid by Berzelius—2 In opium (Smith, Ph [2] 7, 50, Buchanan, B 3, 182)

Formation—1 by the lactic fermentation of milk sugar, cane sugar, or glucose (*v* FERMENTATION, vol II p 543)—2 By the oxidation of propylene glycol by the oxygen of the air in presence of platinum black (Wurtz, A 105, 206, 107, 192)—3 By boiling a chloro propionic acid with water and Ag₂O (Wurtz, A Ch [3] 59, 165, Buff, A 140, 156) In like manner from a bromo propionic acid (Friedel & Maohuca, A 120, 286)—4 By the action of nitrous acid upon alanine (Strecker, A 75, 27, 42)—5 By the reduction of pyruvic acid by sodium amalgam (Wislicenus, A 126, 227) or with zinc in presence of dilute acetic acid (Debus, C J 16, 260)—6 From aldehyde by combination with HCN & a d saponification of the resulting nitrile (Wislicenus, A 128, 6, Simpson & Gauther, A 146, 264)—7 By heating dichloroacetone with a large quantity of water at 200° (Linnemann & Zotta, A 159, 247)—8 By boiling glucose with aqueous NaOH (Hoppe Seyler, B 4, 346)—9 When glucose (20 g) is allowed to stand with potash (40 g) and water (200 cc) at 40° in a flask loosely plugged with cotton wool, it is converted within 24 hours into lactic acid (8 g) and another acid, soluble in alcohol (Nencki & Sieber, J pr 183, 499) Lactic acid may possibly be thus formed in animals from sugar. The decomposition occurs even in very dilute solutions, thus even 9 g of glucose and 9 g of potash dissolved in 8 litres of water and kept at 35°–40° are converted in 10 days into potassium lactate Na₂CO₃ does not decompose

sugar at 40°, nor does NH₃, but NaOH, NMe₃OH and neurine do convert it into lactic acid. Creatinine and guanidine produce no lactic acid. Milk sugar and maltose behave like glucose. Lactic acid is formed when glucose (dextrose) (1 pt), water (10 pts) and KOH (2 pts) are left, even in an atmosphere of hydrogen, for 48 hours at 35°. No sugar is left (Nencki & Sieber, J pr [2] 26, 1, Kiliani, B 15, 701)—10 By heating cane sugar with baryta at 150° (Schutzenberger, B [2] 25, 289)—11 Among the products of the distillation of glycerin with KOH (Herter, B 11, 1167), and formed, together with formic and oxalic acids, by boiling glycerin with potash solution (Debus, A 109, 229)

Preparation—1 The filtered solution of sour whey evaporated nearly to dryness, in strong alcohol, is mixed with alcoholic tartaric acid, as long as any precipitate of tartrate of potassium, sodium, and calcium is formed, the liquid decanted after 24 hours, and evaporated, the residue dissolved in water, the solution digested with carbonate of lead, till lead dissolves in it, the filtrate evaporated, neutralised with carbonate of barium, again filtered, and diluted with water, the whole of the barium precipitated with sulphate of zinc, and the filtrate evaporated till lactate of zinc crystallises out (Berzelius, *Lehrb* Aug 5, v 241)—2 Three kilos of cane sugar and 15 g of tartaric acid (which serves to invert the cane sugar) are dissolved in 13 kilos of boiling water, 1½ kilos of levigated chalk added after two days, together with 60 g of stinking cheese, suspended in 4 kilos of sour milk (decaying cheese favours the production of lactic acid and retards its conversion into butyric acid), the mixture set aside at a temperature between 30° and 35°, and well stirred every day till, in the course of six or eight days, it is converted into a stiff paste of lactate of calcium, this paste is boiled for an hour with 15 g of quicklime and 10 kilos of water, the solution strained through a cloth filter and evaporated to a syrup, the crystalline mass, which forms in four days, pressed, first by itself, then three or four times, after having been each time stirred up, with $\frac{1}{2}$ of its weight of cold water, and the lactate of calcium thus purified is dissolved in twice its weight of boiling water. To the solution of every 32 pts of the calcium salt there is then added a mixture of 7 pts oil of vitriol and 7 pts water, the lactic acid, whilst still hot, is strained through linen to separate it from sulphate of lime, the filtrate obtained from 7 pts of oil of vitriol is boiled with 1½ pts carbonate of zinc for a quarter of an hour (by longer boiling a very sparingly soluble basic salt is formed), the liquid is filtered boiling hot, the colourless crystalline grains of lactate of zinc, which separate on cooling, are freed from sulphuric acid by washing with cold water, and additional quantities of crystalline grains are obtained by evaporating the mother-liquor almost to the end. Lastly, 1 pt of the zinc salt is dissolved in 7½ pts of boiling water, sulphuretted hydrogen passed through the solution as long as sulphide of zinc is precipitated, and the filtrate boiled and evaporated on the water bath to a syrup, whereupon 8 pts. of the zinc salt yield 5 pts. of syrupy lactic

acid (Bensch, *A* 61, 174) By this process, 100 pts of cane sugar yield 117 pts of lactate of calcium, which, if the sugar was white, is colourless, and does not require to be purified by pressure (*cf* Engelhardt a Maddrell, *A* 63, 83, 70, 241, Boutron a Frey, *J Ph* 27, 841) 8 Lautemann (*A* 113, 242) recommends the following modification of Bensch's process of preparation—Retaining the proportions of sugar, tartaric acid, milk, and cheese indicated by the latter, he takes one third more water, uses 1,200 g oxide of zinc (commercial zinc white) instead of levigated chalk, and keeps the temperature as constantly as possible between 40° and 45° during the fermentation. After eight or ten days, the inside of the vessel is lined with white crystals of lactate of zinc, which can be obtained pure by one or two crystallisations from boiling water. The lactic acid prepared from the zinc salt generally contains mannite, which does not completely crystallise out from the concentrated acid. To separate this, the aqueous acid is shaken up with ether, and then the ethereal layer is pipetted off and evaporated; it then leaves pure lactic acid—4 The following mixture is recommended by C O Harz (*Vierteljahrsschrift pr Pharm* 20, 501), 3 pts milk sugar, 36 pts ordinary water, 0.5 to 0.75 pt flour containing a large proportion of gluten, a little beer yeast, 6 pts of soda crystals, or 3 pts of sodium bicarbonate. When the fermentation has once been set up by milk sugar, it may be continued by addition of cane sugar—5 By the action of NaOH or KOH on dextrose or levulose, the operation being performed as follows—A solution of 500 grms of cane sugar in 250 cc of water and 10 cc dilute sulphuric acid (3 pts H_2SO_4 to 4 pts H_2O) is heated to 50° in a closed vessel for 3 hrs. After cooling, 400 cc of aqueous NaOH (50 p.c.) is slowly added. The mixture is then warmed to 60°–70° till it no longer reduces Fehling's solution, the calculated quantity of H_2SO_4 (same strength as before) is then added, and the Na_2SO_4 made to crystallise out by cooling and agitation. The mass is extracted with 93 p.c. spirit and filtered, the filtrate is divided into two portions, one half being neutralised with $ZnCO_3$, filtered hot and the other half added. On cooling, the zinc lactate crystallises out in a nearly pure state, the yield is 200 grms (Kihani, *B* 15, 699, *cf* Hoppe Seyler, *B* 4, 346)

Properties—Colourless syrup with very sour taste. Hygroscopic. Miscible with water and alcohol, sl. sol. ether. Does not solidify at –24°

Reactions—1 When gradually heated it gives off water at 130° leaving solid lactide. At 250° to 300° the products are CO , CO_2 , aldehyde, and lactide—2 Dilute H_2SO_4 at 130° gives aldehyde and formic acid (Erlenmeyer, *Z* 1868, 348) $CH_3CH(OH)CO_2H = CH_3CHO + HCO_2H$ 8 When gently heated with conc H_2SO_4 it gives off CO freely (Pelouze, *A Ch* [3] 13, 257)—4 Boiling nitric acid forms oxalic acid—5 Distillation with $NaCl$, dilute H_2SO_4 , and MnO_2 yields aldehyde and chloral (Städeler, *A* 69, 392)—6 Distillation with MnO_2 and dilute H_2SO_4 yields aldehyde and CO_2 —7 Fuming H_2SO_4 gives methane disulphonic acid (Strecker, *A* 118, 291)—8 Chromic acid mixture gives

acetic acid and CO_2 (Chapman a Smith, *Z* 1867, 477)—9 $KMnO_4$ gives pyruvic acid—10 $POCl_3$ acting on dry calcium lactate gives chloro-propionyl chloride $CH_3CHClCOCl$ whence water forms a chloro propionic acid 11 HIAg reduces it to propionic acid (Lautemann, *A* 113, 217)—12 A concentrated solution of potassium lactate submitted to electrolysis yields aldehyde and CO_2 (Kolbe, *A* 113, 244, Brestre, *Z* 1866, 680)—13 Distillation with quicklime yields alcohol C_2H_5O , $= CO_2 + C_2H_5O$ (Hanriot, *C R* 101, 1156, *Bl* [2] 45, 80)—14 Heated at 170° in a stream of gaseous HBr , or at 100° in sealed tubes with conc $HBrAg$, it yields a bromo propionic acid (Kekulé, *A* 130, 11)—15 Bromine at 100° decomposes lactic acid (Beilstein, *A* 120, 227) Br acting on an ethereal solution of lactic acid forms tribromo pyruvic ether (Wichelhaus, *A* 143, 10, Khimenko, *J R* 8, 125)—16 The dry distillation of calcium lactate produces CO_2 , ethylene, propylene (Gossin, *Bl* [2] 43, 49), acrylic acid, phenol (?) (Claus, *A* 136, 287), and other products—17 Distillation of calcium lactate with soda lime yields acetic, propionic, butyric, hexoic, and other fatty acids. Heating calcium lactate with KOH at 280° yields formic, acetic, propionic, butyric, and oxalic acids (Hoppe Seyler, *H* 3, 352)—18 Among the products of the nutritive fermentation of calcium lactate are hydrogen, CO_2 , acetic, propionic, butyric, and n valeric acids and ethyl alcohol (Pasteur, *Bl* 1862, 52, Strecker, *A* 92, 80, Fitz, *B* 11, 1898, 12, 479, 13, 1309)—19 Heating with m amido benzoic acid forms $CH_3CH(OH)CONH C_6H_4CO_2H$ crystallising from water in small prisms [162°] (Pellizzari, *A* 232, 154), which at 240 forms an anhydride CH_3CH

$\begin{array}{c} | \\ >N C_6H_4 CO_2H \\ CO \end{array}$ [243°] The corre

sponding acetyl derivative

$CH_3CH(OAc)CONH C_6H_4CO_2H$ melts at 148°

Estimation—The substance, acidified with H_2SO_4 , is extracted with ether, the ethereal solution evaporated, the residue treated with water and the aqueous solution ppt with lead acetate and filtered. The filtrate is then ppt with alcoholic NH_3 , and the pp of $PbO_2 \cdot 2(C_2H_5O_2)$ washed with alcohol, dried, weighed, ignited, and weighed again (Palm, *Fr* 26, 33)

Salts—The crystalline lactates do not effloresce in the air, but give off water *in vacuo*. They are not decomposed at 150°. They are insoluble in ether and, for the most part, sparingly soluble in cold water—Ammonium salt forms deliquescent prisms, and gives off NH_3 when exposed to air— NaA' (at 140°) amorphous, deliquescent mass, v sol water and alcohol, ppt by ether from its alcoholic solution— $Na_2C_2H_3O_2 \cdot 2e$ $CH_3CH(ONa)CO_2Na$ obtained by the action of sodium on the preceding at 130°. Hard, deliquescent brittle mass. Decomposed by cold water, with evolution of heat, into $NaOH$ and $NaC_2H_3O_2$. Absorbs CO_2 from the air, forming Na_2CO_3 and sodic lactate. Basic sodium lactate appears to dissolve without decomposition in perfectly dry alcohol. With MeI it gives NaI and $CH_3CH(OMe)CO_2Na$ (Wischneus, *A* 125, 49)—Potassium salt crystallises with difficulty— BaA' , $4aq$ (at 100°):

large cauliflower-like bundles of rectangular needles (Hans Meyer, *B* 19, 2454) Deliquescent, v sol dilute alcohol, insol absolute alcohol and ether— $\text{BaH}_2\text{A}'$, crystals, v sol water Not altered by exposure to air— CaA' , 5aq small white mammillated crystals (from water or alcohol) *S* 10.5 in the cold Extremely soluble in boiling water Sol hot, nearly insol cold, alcohol At 100° it becomes CaA'_2 , and at 280° it is converted into $\text{CaC}_2\text{H}_3\text{O}_6$ (Wurtz a Friedel, *A Ch* [3] 63, 134)— $\text{CaH}_2\text{A}'$, 3aq crystals resembling wavelite, sol absolute alcohol (Engelhardt a Maddrell, *A* 63, 119)— $\text{CaK}_2\text{A}'$, octahedra Deposits CaA' when dissolved in warm water (Strecker, *A* 91, 352)— $\text{CaNa}_2\text{A}'$, 2aq granules (*S*) CaCl_2 3aq prisms, v e sol water (*E a M*)— $\text{Ca}_2(\text{CHO})_2(\text{C}_2\text{H}_3\text{O}_6)\text{Cl}$, 10aq from calcium chloride, formate, and lactate (Böttger, *A* 188, 329) Long needles— SrA' , 3aq very soluble— MgA' , 3aq prisms, insol alcohol, less soluble than the corresponding sarcosylactate *S* 3.6 in the cold, 16.7 at 100° — $\text{Al}_2\text{A}'$, triclinic octahedra (Hans Meyer, *B* 19, 2454)— $\text{AlNa}_2\text{A}'$, 5aq rectangular prisms and tables— FeA' , 3aq small greenish crystals *S* 2.1 at 10° , 8.5 at 100° Insol alcohol—Ferric lactate is a brown amorphous deliquescent mass, v sol water— MnA' , 3aq amethyst coloured monoclinic crystals, m sol cold, v sol hot, water— CoA' , 3aq peach blossom coloured needles, nearly insol cold, m sol boiling water, insol alcohol— NiA' , 3aq apple green needles— ZnA' , 3aq shining crusts, or large crystals irregularly grouped *S* 1.07 at 8° (Buff *A* 140, 160), 1.8 at 10° (Wislicenus, *A* 126, 228), 1.9 at 15° (Strecker *A* 105, 316), 16.7 at 100° Almost insol alcohol, which partly converts it into amorphous ZnA' , 3aq, which again takes up 2aq when exposed to the air (Khimenko, *J R* 12, 98)— ZnA N_2H_4 — ZnA' , N_2H_4 (Lutschak, *B* 5, 30)— $\text{ZnNa}_2\text{A}'$, 2aq— CdA' , small needles Anhydrous when deposited from a boiling solution Insol alcohol *S* 10 in the cold, 12.5 at 100° — $\text{BiC}_2\text{H}_3\text{O}_6$ (Brüning, *A* 104, 194)— CuA' , 2aq dark blue monoclinic tables (Schabus *J* 1854, 40c) *S* 16.7 in the cold, 45 at 100° *S* (alcohol) 9 in the cold, 4 at 78° Decomposed at 200° giving aldehyde, lactide, and CO_2 (Engelhardt, *A* 70, 249)— $\text{CuC}_2\text{H}_3\text{O}_6$, v sl sol water— $\text{Hg}_2\text{A}'$, 3aq rose-coloured or crimson crystals, sl sol water, obtained by mixing the boiling solutions of mercurous nitrate and sodium lactate (*E a M*)—Prisms of the mercurous salt $\text{Hg}_2\text{A}'_2$ are also formed by boiling aqueous lactic acid with HgO (Brunner) — $\text{SnC}_2\text{H}_3\text{O}_6$, crystalline powder, insol water— PbA' , gummy, v sol water— $\text{PbC}_2\text{H}_3\text{O}_6$ (Moldenhauer, *A* 131, 333)— $\text{PbA}'_2\text{O}_2$, 3aq heavy granular pp, formed when lactic acid is mixed with lead acetate and alcoholic NH_3 — UroA' yellow crystalline crusts— AgA' 3aq silky needles *S* 5 in the cold *V* sol hot, nearly insol cold, alcohol

Nitrosyl derivative

$\text{CH}_3\text{CH}(\text{ONO})\text{CO}_2\text{H}$ *S G* 135 Formed by dissolving lactic acid in a mixture of conc HNO_3 and H_2SO_4 , and ppg with water (Henry, *B* 3, 532) Thick oil Sl sol water v e sol ether Decomposes in the cold into HCO_2H and oxalic acid (Henry, *B* 12, 1887)

Acetyl derivative $\text{C}_4\text{H}_7\text{O}_5$, *ie*

$\text{CH}_3\text{CH}(\text{OAc})\text{CO}_2\text{H}$ [167°] (Siegfried) Formed by heating ethyl lactate with AcCl and saponifying the product by heating it with water at 150° for 8 hours (Perkin, *Z* 1861, 166, Wislicenus, *A* 125, 60) Formed also by boiling a solution of zinc acetate and sarcosylactate or lactate (Siegfried, *B* 22, 2715) Occurs in extract of meat. Thin needles, v e sol water Inactive Volatile with steam Decomposed by long boiling with water into acetic and lactic acids Bases quickly effect this decomposition When first prepared it is soluble in alcohol, but on keeping it becomes insoluble in alcohol, does not then melt below 300° , and is saponified with great difficulty by alkalis HI produces no β iodopropionic acid— BaA'_2 , 4aq brittle gumlike mass, v sol water, sol alcohol—Copper salt amorphous deliquescent bluish green mass— ZnA' , gummy mass Its solutions become quickly acid, from conversion into acetic acid and zinc lactate

Benzoyl derivative $\text{C}_{10}\text{H}_{11}\text{O}_5$, *ie*

$\text{CH}_3\text{CH}(\text{OBz})\text{CO}_2\text{H}$ [112°] *S* 25 in the cold Obtained by heating lactic acid with benzoic acid at 180° (Strecker, *A* 80, 42, 91, 360) Formed also by the action of BzCl on calcium lactate (Wislicenus, *A* 183, 277) Tables or needles, m sol boiling water, v sol alcohol and ether Converted by boiling water into benzoic and lactic acids When recrystallised from water benzoyl lactic acid is always accompanied by an oily hydrate $\text{C}_{10}\text{H}_{11}\text{O}_5$, 3aq, which in dry air is slowly converted into the crystalline acids— BaA'_2 , 6aq thin six sided plates— AgA'

Amide $\text{C}_4\text{H}_7\text{NO}_5$, *ie* $\text{CH}_3\text{CH}(\text{OH})\text{CONH}_2$, [74°] Obtained by the action of gaseous or alcoholic NH_3 on lactide (Wurtz a Friedel, *A Ch* [3] 63, 108) Formed also by saturating ethyl lactate with ammonia and allowing the liquid to stand (Brunner, *A* 104, 197), and by heating ammonium lactate in a slow current of dry NH_3 at 130° (Engel, *C R* 98, 574) Small prisms, v sol water and alcohol Does not combine with acids or bases, but is decomposed by them on boiling into NH_3 and lactic acid

Benzoyl derivative of the amide $\text{CH}_3\text{CH}(\text{OBz})\text{CONH}_2$, [124°] From benzoyl lactic ether and alcoholic NH_3 (Wislicenus, *A* 133, 257) White needles, may be sublimed, sl sol water, v sol alcohol Resolved by boiling KOH into lactic and benzoic acids and NH_3 Prolonged treatment with alcoholic NH_3 forms benzamide and lactamide

Isomeric of the amide $\text{C}_4\text{H}_7\text{NO}_5$, Formed by heating ammonium lactate in a current of dry NH_3 at 100° (Engel, *C R* 98, 574) Pale amber coloured syrup Decomposes at 200° In contact with water it immediately forms ammonium lactate

Ethylamide $\text{CH}_3\text{CH}(\text{OH})\text{CONHET}$ [48°] (260°) From lactide and NH_3Et Crystalline (Wurtz a Friedel, *A Ch* [3] 63, 610) Decomposed by alkalis into ethylamine and lactic acid

Anilide $\text{C}_9\text{H}_9\text{NO}_5$, *ie*

$\text{CH}_3\text{CH}(\text{OH})\text{CONHPh}$ [58°] Formed by heating lactic ether with aniline at 150° (Leipen, *M* 9, 48) Colourless prisms, sl sol water, insol ligroin, v sol ether, chloroform, and alcohol

o-Toluide $C_6H_4NO_2$ [72°] From *o*-toluidine and lactic ether Crystalline powder (from benzene) Insol lignroin (Leipen, *M.* 9, 50, 51)

p-Toluide $C_6H_4NO_2$ \cdot $\frac{1}{2}$ $CH_3CH(OH)CO_2NHCH_3$ [102°] From *p*-toluidine and ethyl-lactate White needles $\frac{1}{2}$ sol water

Cyanamide $CN NH(CO CH(OH) CH_3)$
Lacto-cyanamide Formed by dissolving lactide (20 g) in a strong alcoholic solution of potassium cyanide (16 g), passing in CO_2 to remove free alkali and evaporating to crystallisation (Mertens, *J pr* 125, 33) It forms a silver derivative

Methyl ether $C_4H_8O_4$ \cdot $\frac{1}{2}$ $CH_3CH(OH)CO_2Me$ (145° \cdot V) SG $\frac{1}{2}$ 1180 (Schreiner, *A* 197, 1, B 12, 179) Colourless neutral liquid Combines with $CaCl_2$. Is immediately decomposed by water

Ethyl ether $C_4H_8O_4$ \cdot $\frac{1}{2}$ $CH_3CH(OH)CO_2Et$ **Ethyl lactate** (154° \cdot V) SG $\frac{1}{2}$ 10546 Formed by distilling calcium lactate with $KEtSO_4$ (Strecker, *A* 81, 247, 91, 355) Formed also by heating lactic acid (dried at 145°) with alcohol (F & W) and by passing alcohol vapour into lactic acid at 175° (Wislicenus, *A* 125, 58) Colourless liquid, immediately decomposed by water (Schreiner) Forms with $CaCl_2$ the compound $CaCl_2 \cdot 4EtA'$ crystallising in granules Chloral gives a liquid compound, whence phosphorus pentachloride forms liquid $CCl_3CHClOCHMeCO_2Et$ SG $\frac{1}{2}$ 142 (Henry, *Bull Acad Roy Belg* [2] 37, No 5) Lactic ether is a weak hypnotic (Pallacan 5) Berton, *C C* 1887, 1149)

Acetyl derivative of the ethyl ether $CH_3CH(OAc)CO_2Et$ (177°) at 733 mm VD 570 (calc 554) SG $\frac{1}{2}$ 1046 From ethyl lactate and $AcCl$ (Wislicenus, *A* 125, 58) Neutral oil, gradually decomposed by water into alcohol and $CH_3CH(OAc)CO_2H$ Miscible with alcohol and ether

Benzoyl derivative of the ethyl ether $CH_3CH(OBz)CO_2Et$ (288° cor) From ethyl lactate and $BzCl$ at 100°, or from silver benzoyl-lactate and EtI (Wislicenus, *A* 133, 272) Oil, miscible with alcohol and ether Resolved by water at 150° into lactic acid and benzoic ether Alcohol NH_3 gives $CH_3CH(OBz)CONH_2$

Nitroxyl derivative of the ethyl ether $CH_3CH(ONO_2)CO_2Et$ (178°) SG $\frac{1}{2}$ 1153 From ethyl lactate, HNO_3 , and H_2SO_4 (Henry, *B* 3, 532)

Butyryl derivative of the ethyl ether $CH_3CH(O C_3H_7O)CO_2Et$ (208°) SG $\frac{1}{2}$ 1024 From a chloro-propionic ether and potassium butyrate (Wurtz, *A* 112, 235)

Isopropyl ether $CH_3CH(OH)CO_2Pr$ (167°) (Silva, *Bl* [2] 17, 97)

Ethylidene ether $CH_3CH<\begin{smallmatrix} O \\ \diagup \diagdown \\ CO \end{smallmatrix}>CHMe$ (151°) Formed by heating lactic acid with acetic aldehyde at 150° (Leipen, *M* 9, 46). Liquid, sol water Quickly decomposed by hot water into its components

Tri-chloro-ethylidene ether

$CH_3CH<\begin{smallmatrix} O \\ \diagup \diagdown \\ CO \end{smallmatrix}>CHCOCl$ [45°] (228°)

Prepared by heating syrupy lactic acid with excess of chloral for a short time at 150°, and

distilling the product with steam (Wallach, *A* 193, 1) Colourless crystals, readily sol alcohol, ether, and CS_2 , insol water

Methyl derivative $C_4H_8O_4$ \cdot $\frac{1}{2}$ $CH_3CH(OMe)CO_2H$ The Na salt is formed, together with the methyl ether, by treating $CH_3CH(ONa)CO_2Na$ with MeI The free acid is a syrup, volatile with steam It forms an amorphous silver salt $C_4H_7AgO_4$, $\frac{1}{2}$ sol water

Methyl ether of the methyl derivative $C_4H_8O_4$ \cdot $\frac{1}{2}$ $CH_3CH(OMe)CO_2Me$ (185°–188°) (Markownikoff & Krestownikoff, *A* 208, 343) From basic sodium lactate $CH_3CH(ONa)CO_2Na$ and MeI (Wislicenus, *A* 125, 53)

Ethyl ether of the methyl derivative $C_4H_8O_4$ \cdot $\frac{1}{2}$ $CH_3CH(OMe)CO_2Et$ (135° \cdot V) SG $\frac{1}{2}$ 9906 From a bromo propionic ether and $NaOMe$ (Schreiner, *A* 197, 1) Colourless liquid, nearly insol water

Ethyl derivative $C_4H_8O_4$ \cdot $\frac{1}{2}$ $CH_3CH(OEt)CO_2H$ **Ethyl lactic acid** (195°–198°) Obtained by decomposing its ether $CH_3CH(OEt)CO_2Et$ with caustic potash or lime Formed also, together with CH_3I , and acrylic acid, by the action of $NaOEt$ on iodoform (Butlerow, *A* 114, 206, 118, 325, *Bl* 1861, 9) Liquid, partly decomposed by distillation Miscible with water, alcohol, and ether, but separated from its aqueous solution by $CaCl_2$ or Na_2SO_4 Decomposes carbonates Alkalis do not convert it into lactic acid and alcohol When heated with conc $HIAq$ there is formed lactic acid and EtI

Salts — CaA' , 2aq flat prisms, $\frac{1}{2}$ sol water — AgA' bunches of slender silky needles (from hot water)

Ethyl ether of the ethyl derivative $C_4H_8O_4$ \cdot $\frac{1}{2}$ $CH_3CH(OEt)CO_2Et$ (155° \cdot V) (Schreiner, *B* 12, 179) SG $\frac{1}{2}$ 9498 VD 505 (calc 506) Formed by the action of $NaOEt$ on a chloro propionic ether (Wurtz, *A Ch* [3] 59, 169) Formed also by treating lactic ether with sodium and EtI (Wurtz & Friedel, *A Ch* [3] 63, 103) Also from silver ethyl lactate and EtI Colourless liquid, nearly insol water, sol alcohol and ether Alkalis convert it into alcohol and ethyl lactic acid

Amide of the ethyl derivative $CH_3CH(OEt)CONH_2$ **Lactamethane** [63°] (219°) Formed by allowing $CH_3CH(OEt)CO_2Et$ to stand a few days with aqueous NH_3 (Wurtz, *A Ch* [3] 59, 174) Broad plates, sol water, alcohol, and ether Decomposed by distillation with potash into NH_3 and lactic acid

Phenyl derivative $CH_3CH(OPh)CO_2H$ **Phenoxy propionic acid** [113°] Formed from a chloro propionic acid (25 g), strong caustic soda (to neutralisation), and sodic phenylate (24 g) The liquid is evaporated till it becomes thick, dissolved in water, and treated with HCl (L Saarbach, *J pr* 129, 152) Glassy needles (from water) Sol cold water, volatile with steam, $\frac{1}{2}$ sol hot water, alcohol, and ether. Aqueous solutions give a yellow pp with $FeCl_3$. Its salts are soluble in water — NaA' Exhibits rotatory action while dissolving in water Deliquescent — KA' 14aq at 180° — CaA' , 2aq — AgA' sharp needles, blackened by light

Ethyl ether of the phenyl derivative EtA' (244°) SG $\frac{1}{2}$ 1360 Formed when an alcoholic solution of the acid is allowed to stand

More rapidly by passing HCl into such a solution

Amide of the phenyl derivative
 $\text{CH}_3\text{CH}(\text{OPh})\text{CONH}_2$ [180°] Formed from the ether by aqueous ammonia. Crystallises from hot water in long needles. V sol alcohol and ether. Dissolves in hot HCl, on cooling crystals of the hydrochloride of the amide separate.

Bromo-phenyl derivative
 $\text{CH}_3\text{CH}(\text{OC}_6\text{H}_4\text{Br})\text{CO}_2\text{H}$ *Bromo phenoxy propionic acid* [106°] Formed by the action of bromine water on a solution of phenylated lactic acid. Crystallised from alcohol. V sol alcohol and ether, sl so water. Boiling aqueous NaOH cannot turn out the bromine, hence Br is in the benzene nucleus (Saarbach, *J pr* [2] 21, 157) — NaA. Deliquescent needles.

Thymyl derivative
 $\text{C}_6\text{H}_5\text{PrMe O CHMe CO}_2\text{H}$ Formed by heating thymol with α -chloro propionic acid in presence of a 50 p.c. solution of KOH, acidifying with HCl, and adding ammonium carbonate (Seichlone, *G* 12, 48). The acid from synthetical thymol crystallises in prisms [74°], v sol alcohol, ether, and chloroform. The acid from natural thymol crystallises in needles [48°], and forms very soluble and amorphous Ba and Ag salts.

p-Benzyl-phenyl derivative
 $\text{C}_6\text{H}_5\text{CH}_2\text{C}_6\text{H}_4\text{O CHMe CO}_2\text{H}$ [102°] From p-benzyl phenol, KOH, and α -chloro propionic acid (Mazzara, *G* 12, 264).

Benzyl p-tolyl derivative
 $\text{C}_6\text{H}_5\text{CH}_2\text{C}_6\text{H}_4\text{Me O CHMe CO}_2\text{H}$ [115°] Formed in like manner (Mazzara). Small crystals, sl sol water, v sol alcohol and ether. Its solutions give a yellow turbidity with ferric salts and crystalline pps with lead acetate and AgNO_3 .

Allophanyl derivative
 $\text{NH}_2\text{CO NH CO O CHMe CO}_2\text{H}$ [190°] Formed by passing gaseous cyanic acid into an ethereal solution of lactic ether and saponifying the resulting allophanyl lactic ether with conc HClAq at 100° (Traube, *B* 22, 1572). Minute colourless needles, m sol cold, v e sol boiling alcohol or water. When heated above 190° it splits up into lactic and cyanic acids — AgA' white powder, decomposed by boiling water — PbA', crystalline pp.

Ethyl ether of the allophanyl derivative Et' [170°] Colourless needles, v sol hot alcohol and hot water, v sl sol ether. Decomposed by alkalis into CO_2 , ammonia, alcohol, and lactic acid. Ammonia yields biuret.

Isoamyl ether $\text{C}_6\text{H}_{11}\text{A}$ [131°].

Monobasic anhydride

$\text{C}_6\text{H}_{10}\text{O}_5$ i.e. $\text{CH}_3\text{CH}(\text{OH})\text{CO O CHMe CO}_2\text{H}$ *Dilactic acid* Formed when aqueous lactic acid is left for several months over sulphuric acid *in vacuo* (Wislizenus, *A* 164, 181). Requires 1 mol of KOH for each mol of $\text{C}_6\text{H}_{10}\text{O}_5$ to neutralise it, but the neutral solution gradually becomes acid from liberation of free lactic acid, potassium lactate being also formed. By heating lactic acid at 140° this anhydride is formed together with lactide. It may also be formed from α -bromo propionic acid and potassium lactate (Brüggen, *Z* 1869, 338). It forms

amorphous Mg and Ca salts. The ethyl ether $\text{CH}_3\text{CH}(\text{OH})\text{CO O CHMe CO}_2\text{Et}$ (c 235°) S G 2 1 134 is formed by the action of chloro-propionic ether on potassium lactate (Wurtz & Friedel, *A Ch* [3] 63, 112). It is decomposed when heated with water into lactic acid and alcohol.

Di-ethyl ether of the di-basic anhydride $\text{C}_6\text{H}_{10}\text{O}_5$ i.e. $(\text{CH}_3\text{CH}(\text{CO}_2\text{Et}))_2\text{O}$ or $\text{CH}_3\text{CH}(\text{OEt})\text{CO O CHMe CO}_2\text{Et}$ (190° *in vacuo*) Formed by treating α -chloro propionic ether with $\text{CH}_3\text{CH}(\text{ONa})\text{CO}_2\text{Et}$ at 115° (Brüggen, *A* 148, 224). Scarcely attacked by conc KOHAq. Alcoholic KOH gives lactic acid and ethyl lactic acid. NH_3 in ether forms an oily amide $\text{C}_6\text{H}_{10}\text{NO}_5$, decomposed by KOH giving lactic and ethyl-lactic acids.

Neutral anhydride $\text{C}_6\text{H}_{10}\text{O}_5$ i.e.

$\text{CH}_3\text{CH} < \begin{smallmatrix} \text{CO} \\ \text{O} \end{smallmatrix} > \text{CH CH}_3$ *Lactide* [124 5°]

(255°) V D 4 81 (calc 4 96) (Henry, *B* 7, 753). Formed by the dry distillation of lactic acid (Gay Lussac & Pelouze, *A* 7, 43, Pelouze, *A* 53, 116, Engelhardt, *A* 70, 243, Wurtz & Friedel, *A Ch* [3] 63, 101). Prepared by passing dry air through lactic acid at 150° (Wislizenus, *A* 167, 318). Monoclinic tables (from alcohol). May be sublimed. V sl sol. hot water, but gradually converted thereby into lactic acid. Bases quickly convert it into lactic acid. Ammonia gives lactamide. Ethylamine gives the ethylamide of lactic acid. $\text{CH}_3\text{CH}(\text{OEt})\text{CO}_2\text{Et}$ forms a compound $\text{C}_{11}\text{H}_{20}\text{O}_5$ (270°) decomposed by potash into alcohol and lactic acid.

Nitrile $\text{C}_6\text{H}_9\text{NO}$ i.e. $\text{CH}_3\text{CH}(\text{OH})\text{CN}$ *Aldehyde cyanhydrin* (183°) Formed in the cold by allowing a mixture of aldehyde (1 mol.) and anhydrous HCN to stand for 9 days (Maxwell Simpson & Gautier, *Bl* [2] 8, 277). Liquid, not solidified at -21°. Partially decomposed into its components by distillation. Miscible with water, alcohol, and ether. Aqueous KOH forms KCy and aldehyde (or aldehyde resin). Conc HClAq acts violently upon it, at 0° the products are lactic acid and NH_4Cl .

Sarcolactic acid $\text{C}_6\text{H}_8\text{O}_5$ i.e.

$\text{CH}_3\text{CH}(\text{OH})\text{CO H}$ *Paralactic acid* (Heintz, *P* 75, 391) $[\alpha]_D = 3.5^\circ$. Occurs in muscular tissue, thymus and thyroid gland, urine after much exercise, spleen, lymphatic glands, and in pig's bile (Liebig, *A* 62, 278, 326, Wislizenus, *A* 167, 302, Strecker, *A* 123, 354, Colasanti & Moscatelli, *H* 12, 416, *G* 17, 548, 18, 548, Marcuse, *BC* 1887, 92, Nebelhaus, *Zent Biol* 25, 123, Hirschler, *H* 11, 41, Gleiss, *Pf* 41, 69). Sarcolactic acid is absent from living blood, but occurs in blood after death (Salomon, Virchow's *Archiv*, 113, 356, cf. Berlinerblau, *C C* 1888, 757, Vissokovitch, *C C* 1888, 117). Sarcolactic acid may occur sometimes along with ordinary lactic acid as a product of fermentation (Maly, *B* 7, 1567). Its presence is then due to *micrococcus acidiparalactici*, which can convert glucose into sarcolactic acid (Nenoki & Sieber, *M* 10, 532). Sarcolactic acid is formed in the fermentation of moists by cheese (Helger, *A* 160, 336). It is also formed by the action of nitrous acid on the amido propionamide present in urine. A dextro-

rotatory lactic acid is formed by the action of *Penicillium glaucum* on ordinary ammonium lactate (Lewkowitzh, *B* 16, 2720)

Preparation.—1 Chopped flesh is exhausted with cold water, the extract mixed with baryta water, the albumen coagulated by boiling and removed by filtration, and the clear liquid concentrated by evaporation. Sulphuric acid is added to the syrupy residue, and it is shaken with ether, which leaves sarcosolactic acid when evaporated—2 Extract of meat (1 pt) is dissolved in warm water (4 pts) and added with 90 p.c. alcohol. The filtrate is evaporated to a syrup, mixed with 4 pts of alcohol, filtered, evaporated, acidified by H_2SO_4 and extracted with ether (Khimenko, *J R* 12, 17, *Bl* [2] 34, 321)

Properties.—Dextrorotatory syrup, forming levorotatory salts. Resembles ordinary lactic acid in its reactions. In a dry atmosphere it changes in the cold to a levorotatory anhydride $[\alpha]_D = -86^\circ$. At 140° it forms ordinary lactide, whence water produces ordinary inactive lactic acid (Strecker, *A* 105, 313)

Reactions.—1 Hot dilute sulphuric acid splits it up into formic acid and aldehyde—2 Chromic acid mixture gives CO_2 and acetic acid

Salts.— CaA' , 4aq (Engelhardt, *A* 65, 359) S 8 in the cold. V sol boiling water and alcohol— CaA' , 5aq changes into CaA' , 5aq on recrystallisation— MgA' , 4aq. More soluble in water and alcohol than ordinary magnesium lactate— NiA' , 3aq— ZnA' , 2aq. Forms more distinct crystals than ordinary zinc lactate. S (of ZnA' , 2aq) 5.7 at 14.5° , the solubility of ordinary zinc lactate being 1.7 (Wislicenus) S (98 p.c. alcohol) 10.4— ZnA' , 3aq. Ppd by adding alcohol to an aqueous solution of the zinc salt— AgA' , 1/2aq flat needles

Ethyl ether EtA' $[\alpha]_D = -14.2^\circ$. From the silver salt and EtI (Khimenko)

Chloro lactic acid *v* **CHLORO OXY-PROPIONIC ACID**

Chloride of lactic acid *v* **Chloride of α -CHLORO-PROPIONIC ACID**

LACTIDE *v* **Neutral anhydride of LACTIC ACID**

LACTIM A compound of the form

LACTIMIDE C_3H_5NO *s*

$CH_3CH \begin{array}{c} \diagup \text{CO} \\ | \\ \text{NH} \end{array}$ $[275^\circ]$ Produced together with ethylamine and CO_2 by heating alanine in dry HCl at 190° as long as water comes off (Preu, *A* 134, 872). The brown amorphous product is treated with lead hydroxide and H_2S and recrystallised from alcohol. Colourless needles, may be sublimed. V sol water and alcohol. Has a bitter taste. Its solution does not dissolve Ag_2O or give a pp with $ZnCl_2$ or $AgNO_3$.

LACTO-ALBUMEN *v* **MILK**

LACTO-ALBUMOSE *v* **MILK**

LACTO-ZONIC ACID $C_{12}H_{21}O_{17}$. Formed by treating a solution of milk sugar (1 pt) in water (7 pts) with bromine (1 pt) at ordinary temperatures for some days, the bromine is next removed by a stream of air and H_2S , the HBr is

removed with white lead followed by Ag_2O and the metals with H_2S , on treating the syrup so obtained with glacial acetic acid the lacto bionic acid is left. The product is purified by conversion into lead salt, with specially prepared basic lead acetate, and decomposition of the same with H_2S (Emil Fischer & Jacob Meyer, *B* 22, 362). Colourless syrup of strong acid reaction, v sol water, v sl sol alcohol, insol ether. Shows no tendency to crystallise. Does not reduce alkaline copper solutions even on boiling. On warming a short time with dilute mineral acids it splits up into galactose and glycolic acid

LACTOCYANAMIDE *v* **LACTIC ACID**, p 112

LACTONES Anhydrides of oxy acids formed by elimination of water between the hydroxyl and carboxyl groups, both being in the same carbon chain. The name is derived from *lactide* which, until its vapour density had been determined, was written $CH_3CH \begin{array}{c} \diagup \text{O} \\ | \\ \text{CO} \end{array}$. Lactones are usually derived from γ - or from δ -oxy acids. The formula $R''R'C \begin{array}{c} \diagup \text{CH}_2\text{CH}_2 \\ | \\ \text{O CO} \end{array}$ represents a γ lactone, while

$R''R'C \begin{array}{c} \diagup \text{CH}_2\text{CH}_2 \\ | \\ \text{O CO} \end{array} > CH_2$ is a δ lactone (Fittig, *A* 200, 21, 203, 67, 216, 52)

Formation.—1 γ Oxy acids split up in the cold, and immediately on heating their aqueous solution into water and a γ -lactone—2 Formed by boiling their carboxylic acids with dilute H_2SO_4 (Erdmann, *A* 228, 176)—3 From esters of γ oxy acids on distillation, alcohol being split off, *e.g.* oxy isocaproic ether (Bredt), oxy valeric ether (Kissling)—4 From unsaturated acids (*v* *A* 227, 8, 26), *e.g.*

Properties.—Volatile liquids, neutral to litmus. Volatile with steam.

Reactions.—1 γ Lactones do not take up water to form an oxy acid by mere boiling. On the other hand most δ lactones in presence of water, cold or hot, are partially converted into acid, and tend to assume equilibrium with 65 p.c. of lactone to 35 p.c. of acid (Fittig & Wolff, *A* 216, 187, Hantzsch, *A* 222, 28)—2 All lactones are converted into salts of the corresponding oxy acids by boiling with aqueous solutions of alkalis, alkaline earths, and sometimes even with $CaCO_3$ (Fittig, *A* 208, 116). 3 All lactones form compounds with NH_3 , which easily split up into their components (Wolff, *A* 229, 278). These compounds are probably acid amides—4 No lactone at present known reacts with hydroxylamine, but a few aromatic lactones readily react with phenylhydrazine (*e.g.* phthalide). Hence the fact of an oxygen compound reacting with phenylhydrazine cannot be taken (as previously assumed) as a proof of its aldehydic or ketonic nature. This can only be proved by its behaviour towards hydroxylamine (V Meyer & Münchmeyer, *B* 19, 1706). The compound formed with phthalide appears to be $HOCH_2C_6H_4CO \cdot N_2H_5$, ph formed by direct addition (Wislicenus, *B* 20, 401)—5 Lactones (1 mol) appear to react with oxalic ether (1 mol.) in presence of $NaOEt$

(1 mol) Phthalide gives $C_{12}H_{10}O_5$ [122°] and valerolactone also gives a crystalline compound (Wilschusen, *B* 20, 2061)

Lactones are for the most part described in this Dictionary under the oxy acids of which they are the anhydrides

LACTONIC ACID v GALACTONIC ACID

Lactonic acids Acids which are at the same time lactones When warmed with alkalis they give rise by assimilation of water to acids of higher basicity

LACTONITRILE v Nitrile of LACTIC ACID

LACTO-PROTEIN v MILK

LACTOSE or Milk sugar v SUGAR and MILK

LACTOSIN $C_{12}H_{22}O_{11}$ Occurs in the roots of all the Caryophyllaceae, being most conveniently obtained from *Silene vulgaris* (A Meyer, *B* 17, 685) White amorphous powder (anhydr), $[a]_D = +168$, or small glistening crystals ($+H_2O$), $[a]_D = +211.7$ It forms gummy solutions with water, but is sparingly soluble in alcohol The aqueous solution of the crystallised lactosin gives no pps with neutral or basic lead acetate, although a pp is produced by lead acetate and NH_4 Fehling's solution is not reduced on short boiling By boiling with dilute H_2SO_4 it is inverted into lactose and a new sugar

LACTUCARIUM A brownish viscid substance obtained by evaporating juice which exudes from incisions in the leaves and stem of certain species of lettuce, especially *Lactuca virosa* It has an odour resembling opium and acts as a narcotic According to Ludwig (*Ar Ph* [2] 7, 129) it contains (50 p c of) 'lactucone' $C_{14}H_{26}O_8$, a crystalline substance [150°–160°] soluble in boiling alcohol, 'lactucic acid,' lactucin, a wax, and oxalic acid According to Hesse (*A* 234, 243) lactucarium contains the acetyl derivatives of (a) and (b) lactucerin

LACTUCERIN $C_{14}H_{26}O_8$ (L), or $C_{12}H_{24}O_8$ (K), or $C_{10}H_{20}O_8$ (H) *Lactucone* [210°] Obtained by washing lactucarium with benzene and extracting the residue with boiling alcohol, the crystals obtained may be purified by shaking their ethereal solution with aqueous KOH, and ppg by the addition of alcohol and water (Lenoir, *A* 60, 83, Kassner, *A* 238, 220) Lactucerin so prepared forms minute white needles [200°], but after sublimation in CO_2 it melts at 210° On fusion with KOH it gives lactucol $C_{14}H_{26}O_8$, hydrogen, and acetic acid It is dextrorotatory According to Hesse, lactucerin consists of the mono-acetyl derivatives of (a) and (b) lactucerinol From the milk juice of *Lactuca canadensis*, by crystallising from hot alcohol Flowers (*Ph* [3] 10, 44) obtained a 'lactucern' [89°] crystallising in colourless needles

Lactucone $C_{14}H_{26}O_8$ (?) [296°] Microscopic needles Insoluble in water, difficultly soluble in alcohol Occurs in French lactucarium from *Lactuca altissima*, from which it is extracted with 90 p c alcohol Acetic anhydride does not act upon it even at 200° By distillation with P_2S_5 it gave a hydrocarbon of the constitution $C_{14}H_{22}$, boiling between 247°–252° (Franchimont, *B* 12, 10)

Lactucol $C_{14}H_{26}O_8$ [162°] Obtained by fusing lactucerin with KOH (Kassner, *A* 233, 224) Needles Dextrorotatory, $[a]_D = 46^\circ$

Acetyl derivative $C_{16}H_{28}AcO$ [200°]

Like lactucol and lactucerin its solutions in ether, chloroform, and CS_2 are dextrorotatory, $[a]_D = 68^\circ$

(a)-**LACTUCEROL** $C_{14}H_{26}O_8$ [166°–181°] Obtained by exhausting lactucarium with ligroin and extracting the residue with alcohol The crystals so obtained are saponified by alcoholic potash, and the product ppg with water The pp is recrystallised from alcohol, from which (a) lactucerinol separates first (Hesse, *A* 234, 245, 244, 268)

Properties—Crystallises from 90 p c alcohol in silky needles (containing 2aq) From chloroform or ether it separates in anhydrous crystals. Insol water and alkalis It melts at 162°, but after purification by conversion into its di-acetyl derivative and saponification of the product its melting point is higher Conc H_2SO_4 colours its solution in chloroform red It absorbs Br with evolution of HBr It is dextrorotatory, in a 2.3 p c solution in chloroform $[a]_D = 76.2$ at 15° It may be distilled in a current of CO_2

Acetyl derivative $C_{16}H_{28}AcO$ [202°–207°] Occurs in lactucarium, and is formed by heating (a) lactucerinol for a short time with Ac_2O at 80° Small plates, m sol cold alcohol, v sol ether Dextrorotatory

Di-acetyl derivative $C_{16}H_{28}Ac_2O$ [198°–200°] From (a) lactucerinol and Ac_2O by boiling for 2 hours Satiny plates In a 1 p c solution in chloroform $[a]_D = 63.6$ at 15°

Di-propionyl derivative $C_{16}H_{28}(C_2H_5O)_2$ [152°] Minute needles (from alcohol), v e sol $CHCl_3$, and ether

Di-benzoyl derivative $C_{16}H_{28}Bz_2O_2$ [156°] White crystals, insol water, v sol ether and chloroform, sl sol alcohol Saponified by alcoholic potash

(b)-**Lactucerinol** $C_{12}H_{24}O_8$ $[a]_D = 38$ at 15° in a 4 p c solution in chloroform Occurs as a mono acetyl derivative in lactucarium, and separated from its (a)-isomeride by crystallisation from alcohol Long silvery needles (from ether or chloroform) Separates from alcohol as a gelatinous mass (containing 2aq) More soluble in alcohol, and less dextrorotatory than its isomeride

Acetyl derivative $C_{14}H_{26}Ac_2O$ [230°] Plates (from alcohol) Less sol alcohol and ligroin than its isomeride

LACTUCIC ACID Obtained from the juice of *Lactuca canadensis* after separating 'lactucern,' adding water, ppg with lead acetate, decomposing the lead salt with H_2S and evaporating (Flowers, *Ph* [3] 10, 44) Brownish green amorphous substance, with acid, bitter taste. Sol alcohol, insol petroleum spirit, ether, and chloroform Ludwig (*J* 1847, 824) and Wals (*N Jahr Pharm* 15, 118) obtained a substance ($C_{10}H_{20}O_8$, ?) called lactucic acid by triturating lactucarium (1 pt) with dilute H_2SO_4 (1 pt), adding alcohol (5 pts of 84 p c), filtering, shaking the filtrate with slaked lime, decolourising with animal charcoal, evaporating, and crystallising the residue from boiling water Light yellow amorphous mass, gradually becoming crystalline Its solutions are coloured wine-red by alkalis, and reduce boiling Fehling's solution.

LACTUCIN $C_{14}H_{26}O_8$, or $C_{12}H_{24}O_8$, or $C_{10}H_{20}O_8$ S 125 in the cold Occurs in the juice of common lettuce (*Lactuca sativa*) and of *Lactuca*

althusma (Aubergier, *B J* 24, 522, *A* 44, 299, Wals, *A* 82, 85, *N Jahr Pharm* 15, 118, Ludwig & Kromayer, *Ar Ph* [2] 111, 1, Kromayer, *Ar Ph* [2] 105, 3, Buchner, *Rep Pharm* 43, 1, Flowers, *Ph* [3] 10, 44) Obtained by macerating the dried juice with hot water ($\frac{1}{2}$ pt) for four days, pressing the mass, boiling the residue with water, and ppg the filtrate with lead subacetate, removing excess of lead from the filtrate by H_2S , and evaporating Pearly scales (from alcohol). M sol alcohol and HOAc, sl sol ether Conc HNO_3 turns it brown Its solutions are not ppg by ordinary reagents

LACTUCOPICRIN $C_{14}H_{16}O_{11}$. An amorphous very bitter substance which remains in the mother-liquor in the preparation of lactucin (Kromayer, *Die Bitterstoffe*, 1861, Flowers, *Ph* [3] 10, 222) Sol water and alcohol, its solutions not being ppg by lead salts

LACTURAMIC ACID ν **URAMIDO PROPIONIC ACID**

LACTYL CHLORIDE is the chloride of α -CHLORO PROPIONIC ACID

From this urea and a chloro propionic ether at 100° (Freytag, *J pr* [2] 20, 380) Crystalline.

LACTYL-UREA $C_4H_6N_2O_4$: a.

Methyl hydantoin [140°]

(H), [145°] (Urech, *B* 6, 1113) Formed by treating aldehyde ammonia with crude KCy and hydrochloric acid $CH_3CH(OH)NH_2 + HCN + HClNO = NH_4 + C_2H_5N_2O_2$ (Heintz, *A* 169, 120) Formed also by heating uramido propionic acid Prisms, or cauliflower-like tufts (containing aq), v sol water and alcohol, nearly insol ether May be sublimed Tastes bitter Neutral in reaction Boiling baryta water converts it into uramido-propionic acid Heating with barium hydrate at 100° – 140° gives alanine Pure HNO_3 gives a quantitative yield of a nitro derivative, but no gas is evolved (Franchimont, *R T C* 6, 217) — $AgC_2H_5N_2O_2$ formed by treating lactyl urea with moist Ag_2O Insol water, sol NH_4Aq Ppd as a white powder by adding HNO_3 to its ammoniacal solution

LEVULAN $C_7H_{10}O_6$ [250°] $[\alpha]_D = -221^\circ$ Occurs in an impure condition in the residues obtained from desugarising molasses by Steffen's process (Lippmann, *B* 14, 1509) White amorphous powder Sol hot water, the solution gelatinises on cooling By long boiling it becomes much more soluble and loses its power of gelatinising Insol alcohol It does not reduce Fehling's solution but produces a blue pp By HNO_3 it is oxidised to mucic acid Dilute H_2SO_4 at 120° converts it into levulose

LEVULIN $C_5H_8O_4$ (dried at 110°) A substance resembling dextrin, contained in the juice of the tubers of the Jerusalem artichoke (*Helianthus tuberosus*) and of *Dahlia variabilis*, and in oak bark (Ville & Joulie, *Bl* [2] 7, 262, Popp, *A* 156, 181, Dieck & Tollens, *A* 198, 228, *B G* 1879, 275, Etti, *B* 14, 1826, Lefranc, *J Ph* [5] 2, 216, Reidemeister, *J Th* 1881, 68) Prepared by ppg the juice of artichokes with lead acetate, filtering, removing excess of lead by

H_2S , neutralising with $MgCO_3$, filtering and evaporating The residue is extracted with alcohol, until it is optically inactive It is then extracted with absolute alcohol, which leaves inulin undissolved, and ppg with ether

Properties —Amorphous deliquescent mass, optically inactive, but becomes levorotatory on boiling with dilute HCl, being split up into levulose and glucose V sol water and dilute alcohol, sl sol absolute alcohol, insol ether Has an insipid taste Turns brown at 140° forming caramel Not ppg by lead subacetate Reduces Fehling's solution after long boiling Dilute HNO_3 gives oxalic acid and saccharic acid Alkalis do not turn it brown First hydrolysed by yeast and then undergoes alcoholic fermentation Levulin prevents the ppg of ferric and cupric salts by alkalis $AgNO_3$ gives a white pp blackened on heating — $K_2C_2H_3O_6$ ppg by adding alcoholic KOH to its alcoholic solution — $Ba_2C_2H_3O_6$ aq amorphous — $Pb_2C_2H_3O_6$ aq amorphous, ppg by adding an alcoholic solution of lead subacetate to an alcoholic solution of levulin

LEVULINIC ACID ν β **ACETYL PROPIONIC ACID**

LEVULOSE ν **SUGAR.**

LANTHANUM La At w 138.2 Mol w. unknown SG 6.163 Melts between M P of Sb (450°) and that of Ag (950°) (Hillebrand & Norton, *P* 156, 466) SH 04485 (H & A, *N P* 158, 71) SVS 22.4 Chief lines in emission spectrum 5183, 4921, 4920 in the green, 4824, 4655, 4558 in the blue, 4522, 4330, 4268 in the indigo, 4238, 4196, 4086, 4077 in the violet (Thalén) In 1803 Klaproth separated a new earth from a Swedish mineral, the earth was examined by Hisinger and Berzelius and called by them *ceria* (from the planet *Ceres* then recently discovered) In 1839 Mosander showed that *ceria* contained two oxides (*P* 46, 648) the name *ceria* was retained for one, and the other was given the name *lanthana* ($\lambda\alpha\nu\theta\acute{\alpha}\nu\epsilon\iota\nu$ = to be concealed) In 1841 Mosander discovered that *lanthana* was a mixture of two oxides (ν *P* 60, 297), one of these he called *lanthana* and the other *didymia* ($\delta\acute{\iota}\delta\upsilon\mu\omicron\varsigma$ = twofold)

Occurrence —As silicate, with silicates of Ce and Di, in *cerite*, *gadolinite*, *orthite*, &c (Rammelsberg, *P* 107, 631) *Lanthanite*, from Bethlehem in Pennsylvania, U.S., is a carbonate of La and Di (Lawrence Smith, *Am S* [2] 18, 378) La containing minerals occur in small quantities in a few localities

Preparation —The mixed oxides of Ce, La, and Di are separated from *cerite* by treatment with H_2SO_4 , &c, as described under *Cerium* (vol 1 p 723), the oxides are dissolved in HNO_3Aq , the solution is evaporated to dryness the residue is heated to full redness until pale yellow, and then treated with boiling dilute HNO_3Aq in which nitrates of La and Di dissolve while basic Ce nitrate remains insoluble There are various ways of separating La from Di in the nitric acid solution The hydrated oxides may be obtained by ppg with NH_4Aq , the pp is dissolved in H_2SO_4Aq , and the mixed sulphates are obtained by crystallisation, the sulphates are dried and powdered, 1 part is dissolved in small successive portions in 6 parts

water at 2°-3°, the solution is then heated to ca. 40° when $\text{La}_2(\text{SO}_4)_3$ separates nearly free from $\text{D}_1(\text{SO}_4)_3$. The $\text{La}_2(\text{SO}_4)_3$ may be purified by re solution in ice cold water and heating to 40°, the operations being repeated until the sulphate is perfectly white and shows no D₁ lines in the spectrum. Or the solution of $\text{La}_2(\text{SO}_4)_3$ may be pptd by oxalic acid, the pp strongly heated, dissolved in HNO_3 , and fractionally pptd by NH_4Aq , the ppn must be effected from very dilute solutions by means of very dilute NH_4Aq , the first third of the pp contains most of the D₁ oxide, ppn is continued so long as the pp shows D₁ lines in the spectrum. This method gives good results when comparatively much La is present (Mosander, *l.c.*, Bunsen a. Jøgel, *P* 155, 377), but it is slow and laborious. Marignac (*J pr* 48, 406) adds excess of HNO_3 to the solution of the nitrates of La and D₁, heats, and adds oxalic acid, the pp dissolves, when crystallisation begins the solution is allowed to cool, and is then poured off from the pp which is rich in D₁ oxalate, these operations are repeated, a very acid solution of La salt is finally obtained from which NH_4Aq pptts $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$. This method is recommended when much D₁ is present with little La.

The method of Von Welsbach (*Sitz W* 92 [2nd part], 317) was found very good by Robinson (*priv comm*). A large quantity of the mixed nitrates of Ce and La obtained from *cerite* after separating basic Ce nitrate (*v* vol 1 p 723) is mixed with the necessary quantity of NH_4NO_3 , about $\frac{1}{10}$ th part conc HNO_3Aq is added, and the liquid is evaporated until small crystals appear on the surface, a little water is then added, and crystallisation is allowed to proceed for about 24 hours, the crystals are drained and washed with a little HNO_3Aq which is added to the mother liquor, the mother liquor is evaporated and crystallised, the liquor from this is again evaporated, and so on until 6-8 fractions are obtained. The first fraction contains almost all the La. By fractionating the middle fraction, placing the first fractional pp in the former first fraction, and repeating this process a few times, pure $\text{La}(\text{NO}_3)_3$ is obtained. For other methods of separating La salts from salts of Ce and D₁ v Hermann, *J pr* 82, 385, Erk, *Z* [2] 7, 100, Cleve, *Bl* [2] 21, 196, 246.

La_2Cl_6 is obtained by dissolving the pp of $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ (obtained as described above) in HClAq , adding NH_4Cl , evaporating to dryness, and heating strongly in a covered crucible. By reducing La_2Cl_6 by heating with K and washing out KCl in alcohol, metallic La is obtained. Hillebrand a. Norton obtained approximately pure La by electrolysis La_2Cl_6 covered with a fused mixture of KCl and NaCl, using a thick iron wire as negative electrode and a battery of 4 Bunsen's cells (*P* 156, 466, cf Bunsen, *P* 155, 633).

Properties and Reactions—White metal, fairly malleable and ductile, rather harder than Ce. Oxidises rapidly in dry air, but burns only at temperature considerably higher than that at which Ce burns. Decomposes cold water slowly, hot water rapidly. Easily dissolved by acids, including cold conc HNO_3 , which scarcely acts on Ce.

The atomic weight of La has been deter-

mined (1) by converting the oxide into the sulphate and *vice versa* (Rammelsberg, *P* 55, 65, Marignac, *A Ch* [8] 27, 228, [4] 30, 67, Holzmänn, *J pr* 75, 348, Czudnowicz, *J pr* 80, 33, Hermann, *J pr* 82, 395, Zschiesche, *J pr* 104, 174, Erk, *Z* [2] 7, 106, Cleve, *Bl* [2] 81, 196, Brauner, *O J* 41, 75, Crookes, *Pr* 38, 414, (2) by analysing La iodate (Holzmänn, *J pr* 75, 349), (3) by estimating Cl in La chloride (Hermann, *J pr* 82, 395), (4) by converting La carbonate into oxide (Hermann, *l.c.*), (5) by determining S H of La (Hillebrand a. Norton, *P* 158, 71), (6) by considering the chemical relations of La with other elements in the light of the periodic law.

The at w of La was taken for many years as c 92.2, the oxide was formulated LaO and the chloride LaCl . Mendeleeff (*v C N* 41, 49) proposed to multiply the usually accepted at w by 2, and to regard the oxide as LaO_2 , by doing this he placed La in Group IV along with Ce. As the properties of La salts were not much known when Mendeleeff's memoir was published, he did not strongly press the arguments in favour of the position assigned by him to La. Fuller investigation showed that the usually accepted at w of La should be increased by one half, that the oxide should be regarded as similar to the oxides of the earth metals (M_2O_3), and that La should be placed in Group III along with Al, Ga, Sc, &c (*v* **EARTHS, METALS OF THE**, vol II p 424).

La is distinctly metallic in its chemical relations, it forms the oxide La_2O_3 , and there are indications of the existence of a higher oxide, the chloride is La_2Cl_6 or LaCl_3 . La forms several

salts of the form LaX_3 , $\text{X} = \text{NO}_2, \frac{\text{SO}_4}{2}, \frac{\text{PO}_4}{3}$

&c, a few double salts and one or two basic salts are known. The investigation of the La compounds shows that this metal is to be placed with the metals of the earths (Group III), it is more closely related to the even series members of the group (Sc, Y, and Yb) than to the odd series members (Al, Ga, In, Tl). The strongly basic character of La_2O_3 marks the connection of La with the alkaline earths and alkali metals. The examination of La compounds is yet far from complete (*cf* **METALS, RARE**).

Detection and Estimation—Most of the La salts are colourless, the soluble salts have an astringent, sweetish taste, solutions of La salts do not show any absorption-bands. Alkalis, NH_4HS , and KCN, form gelatinous pps insoluble in excess of pptant. Alkali carbonates ppt $\text{La}_2(\text{CO}_3)_3$, BaCO_3 forms a pp without warming, $\text{H}_2\text{C}_2\text{O}_4$ forms a white pp at first curdy, then crystalline, more soluble in acids than the oxalates of Ce and D₁, $\text{Na}_2\text{S}_2\text{O}_3$ does not produce any pp. La salts do not colour beads of borax or microcosmic salt.

La may be estimated as La_2O_3 or $\text{La}_2(\text{SO}_4)_3$. La_2O_3 is obtained (1) by ppg with NH_4Aq , washing as rapidly as possible with water containing NH_3 (to prevent formation of La_2CO_3 and partial solution of La), solution in HNO_3Aq , re ppn by NH_4Aq , washing with NH_4Aq , and strongly heating, (2) by ppg $\text{La}_2(\text{C}_2\text{O}_4)_3$ by addition of $\text{H}_2\text{C}_2\text{O}_4$ and standing, washing, and heating to white heat. $\text{La}_2(\text{SO}_4)_3$ is obtained by ppg with

NH_4Aq , as above, dissolving in warm dilute $\text{H}_2\text{SO}_4\text{Aq}$, evaporating to dryness at 100° , and gradually heating to redness

Lanthanum, arsenate of $\text{La}_2(\text{HASO}_4)_3$, and arsenite of $\text{La}_2(\text{HASO}_3)_3$, v Smith, *A* 191, 331 Lanthanum, borate of $(2\text{La}_2\text{O}_3 \cdot \text{B}_2\text{O}_3)_n$, obtained, along with crystals of La_2O_3 , by dissolving La_2O_3 in molten borax (Nordenskjöld, *J* pr 85, 431)

Lanthanum, bromide of $\text{La}_2\text{Br}_6 \cdot 14\text{H}_2\text{O}$, or $\text{LaBr}_3 \cdot 7\text{H}_2\text{O}$. Colourless crystals, e sol water or alcohol, obtained by dissolving $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HBrAq and evaporating (Cleve, *Bl* [2] 89, 151, 43, 56) By the action of Br in vapour on La_2O_3 , the oxybromide LaOBr is obtained (Frerichs a Smith, *A* 191, 331) Double salts are described by Cleve (*l c*) — $\text{La}_2\text{Br}_6 \cdot 2\text{AuBr}_3 \cdot 18\text{H}_2\text{O}$, $\text{La}_2\text{Br}_6 \cdot 3\text{ZnI}_2 \cdot 27\text{H}_2\text{O}$, also by F a S (*l c*), $\text{La}_2\text{Br}_6 \cdot 3\text{NiBr}_2 \cdot 18\text{H}_2\text{O}$, and $\text{La}_2\text{Br}_6 \cdot 3\text{ZnBr}_2 \cdot 39\text{H}_2\text{O}$

Lanthanum, carbide of A carbide of La is said to be produced by heating the oxalate or formate in absence of air, it is described as similar to, but more easily acted on by acids than, Ce carbide (Delafontaine, *C N* 11, 253)

Lanthanum, chloride of La_2Cl_6 or LaCl_3 A white crystalline mass, e sol water or alcohol Obtained by adding NH_4Cl to a solution of $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HClAq , evaporating to dryness, and heating in a closed crucible until all NH_4Cl is volatilised (Hermann, *J* pr 82, 406, Hillebrand a Norton, *P* 158, 71) Mosander (*P M* 23, 241) says that LaCl_3 can be obtained by evaporating $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HClAq to dryness, and heating the residue in a stream of HCl gas

By slowly evaporating $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HClAq , large colourless triclinic crystals of $\text{LaCl}_3 \cdot 7\text{H}_2\text{O}$ are obtained Double salts are described by Smith (*A* 191, 331), and Cleve (*Bl* [2] 21, 196, 39, 151) — $\text{M} 9\text{H}_2\text{Cl}_2 \cdot 24\text{H}_2\text{O}$,

$\text{M} 3\text{PtCl}_2 \cdot 24\text{H}_2\text{O}$, $\text{M} 2\text{PtCl}_2 \cdot 26\text{H}_2\text{O}$, $\text{M} 8\text{AuCl}_3 \cdot 21\text{H}_2\text{O}$, $\text{M} 2\text{AuCl}_3 \cdot 20\text{H}_2\text{O}$ ($\text{M} = \text{La}_2\text{Cl}_6$) Oxychlorides are obtained by heating the hydrated chloride in air, and by the action of Cl on La_2O_3 (v LANTHANUM, OXYCHLORIDES OF)

Lanthanum, chromate of $\text{La}_2(\text{CrO}_4)_3 \cdot 8\text{H}_2\text{O}$, v. Smith, *A* 191, 355

Lanthanum, cyanide of LaCy_3 , v. vol u p. 341

Lanthanum, fluoride of $\text{La}_2\text{F}_6 \cdot \text{H}_2\text{O}$ A gelatinous pp by adding HFAq to solution of La acetate (Cleve, *Bl* [2] 89, 151, 43, 56) From solution of La sulphate, Smith obtained a pp of $\text{La}_2\text{F}_6 \cdot 3\text{HF}$ (*A* 191, 331) According to Marignac, H_2SiF_6 pptts La_2F_6 from La salts (*J* pr 48, 406)

Lanthanum, hydroxide of $\text{La}_2\text{O}_3 \cdot \text{H}_2\text{O}$, or La_2O_3 , may also be regarded as *hydrated oxide* $\text{La}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ A white gelatinous pp by adding KOH Aq or NaOH Aq to solution of a La salt (NH_4Aq pptts basic compounds) Also produced by action of warm water on La_2O_3 $\text{La}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is a strongly basic hydroxide, it turns red litmus blue, decomposes NH_4ClAq on warming with evolution of NH_3 , absorbs CO_2 from the air, reacts with acids to form salts

LaX_3 ($\text{X} = \text{NO}_2, \frac{\text{SO}_4}{2}, \frac{\text{PO}_4}{3}$, &c) Thomsen gives

the heat of neutralisation with $\text{H}_2\text{SO}_4\text{Aq}$ and HClAq as $[\text{La}^\circ\text{O}^\circ\text{H}^\circ \cdot 3\text{H}^\circ\text{SO}^\circ\text{Aq}] = 82,820$; $[\text{La}^\circ\text{O}^\circ\text{H}^\circ \cdot 6\text{HClAq}] = 74,970$ (*Th.* 1, 375).

Lanthanum, haloid compounds of. LaF_3 , LaCl_3 , and LaBr_3 have been isolated, the formulae may be written La_2F_6 , &c, as none of these compounds has been gasified All form hydrates, and all combine with haloid compounds of Au and some other heavy metals to form double salts Oxychlorides and oxybromides, LaOX , are known

Lanthanum, iodide of LaI_3 has not been isolated, but the double salt $2\text{LaI}_3 \cdot 3\text{ZnI}_2 \cdot 27\text{H}_2\text{O}$ is described by Frerichs a Smith (*A* 191, 355)

Lanthanum, oxides of Only one oxide, La_2O_3 , is known with certainty, there are indications of the existence of an oxide containing more O

LANTHANUM SESQUIOXIDE, La_2O_3 Obtained by strongly heating $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, or the oxalate, or any La salt the acid of which is volatilisable Forms a white, amorphous, infusible powder, SG 6.48–6.53 (Cleve, *l c*, Nilsson a Pettersson, *B* 13, 1464) SH 0749 (N a P, *l c*, v also *Pr* 31, 46) Diamagnetic (N a P, *l c*) Combines with water to form $\text{La}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ (v LANTHANUM, HYDROXIDE OF) Easily sol in acids Nordenskjöld (*J* pr 85, 431) obtained La_2O_3 in lustrous rhombic crystals, $abc = 56581 \cdot 6863$, SG 5.296, by dissolving the amorphous oxide in borax in a porcelain oven, the crystals did not directly combine with water, but were easily sol in acids The great infusibility of La_2O_3 , and its power of emitting white light when strongly heated, render it useful as a light giver, Von Welsbach has patented an arrangement whereby La_2O_3 is heated in the flame of a Bunsen lamp and emits a clear white light (English Patent, 15,286, July 1886).

LANTHANUM PEROXIDE According to Mosander (*P M* 23, 241) a peroxide of La is ppd by adding BaO_2 to a neutral La salt, on drying it loses O Hermann (*J* pr 82, 397) says that a peroxide is obtained by heating oxalate, nitrate, or carbonate of La in the air, it dissolves in HClAq with evolution of Cl, heated in H it yields La_2O_3 Zschiesche (*J* pr 104, 74) was unable to confirm Hermann's observations Cleve (*Bl* [2] 43, 56) by ppg La salts by alkali and $\text{H}_2\text{O}_2\text{Aq}$ obtained an oxide to which he assigned the composition La_2O_5

Lanthanum, oxybromide of LaOBr Obtained by the action of Br vapour on heated La_2O_3 (Frerichs a Smith, *A* 191, 331)

Lanthanum, oxychlorides of LaOCl and $\text{La}_2\text{O}_2\text{Cl}_2$ ($= 3\text{La}_2\text{O}_3 \cdot \text{La}_2\text{Cl}_6$) The former is a greyish mass, unchanged by water, obtained by heating La_2O_3 in Cl to 200° (Frerichs a Smith, *A* 191, 331, Cleve, *Bl* [2] 89, 151, 43, 56) The latter is obtained by heating $\text{LaCl}_3 \cdot 7\text{H}_2\text{O}$ and washing the residue with water (Hermann, *J* pr. 82, 385)

Lanthanum, salts of. La forms one series of salts, LaX , where $\text{X} = \text{NO}_2, \frac{\text{SO}_4}{2}, \frac{\text{PO}_4}{3}$, &c Most

of the La salts are colourless, those which are soluble have a sweetish astringent taste The salts of volatilisable acids yield La_2O_3 when strongly heated La_2SSO_4 combines with the alkali sulphates, but the products are not alums A good many double La salts are known, a few basic salts have been isolated. The following are the chief La salts. *arsenate, arsenite, borate,*

bromate, carbonate, chlorate, chromate, hypochlorite, iodate, molybdate, nitrate, perchlorate, periodate, phosphates, phosphite, selenate, selenite, silicate, sulphates, sulphites, thiosulphate, tungstate, v CARBONATES, NITRATES, SULPHATES, &c

Lanthanum, sulphide of La_2S_3 , Red-yellow, microscopic crystals, obtained by the action of 8 parts Na polysulphide with 1 part La_2O_3 , and washing with water (Beringer, *A* 42, 134) Mosander obtained a greyish powder by heating La_2O_3 in CO_2 laden with CS_2 (*P* 60, 297), and by a similar reaction Frichs & Smith (*A* 191, 355) obtained La_2S_3 as a brownish grey powder, soluble in acid with evolution of H_2S , decomposed by water to LaO_2H_3 and H_2S Didier (*C R* 100, 1461) obtained a similar body by heating La_2O_3 in H_2S gas M M P M

LAN-HOPINE $\text{C}_{22}\text{H}_{23}\text{NO}$, [α 200°] A base homologous with papaverine, occurring in opium (Hesse, *A* 153, 57, *Suppl* 8, 271, *C C* 1870, 168)

Preparation—The aqueous extract of opium is pptd by Na CO_3 , the pp dissolved in ether, the ethereal solution shaken with dilute HOAc, and the acid solution poured into aqueous NaOH After 24 hours the ppt thebaine and papaverine are filtered off, the filtrate neutralised with HCl, pptd by NH_3 , and shaken with chloroform The chloroform takes up codeine, lanthopine, and meconidine, and is then shaken with dilute HOAc, and the solution exactly neutralised by NaOH, when lanthopine is pptd

Properties—White powder composed of minute prisms (from CHCl_3) Insol water, nearly insol alcohol, v sl sol ether and benzene, m sol chloroform When pptd from solutions by KOH or lime it dissolves in excess of the precipitant NH_3 gives a pp insol excess It does not give a blue colour with FeCl_3 Conc HNO_3 gives an orange red colour H_2SO_4 gives no colour in the cold, but a brownish yellow colour at 150°

Salts—The sulphate forms extremely thin needles— $\text{B}^+\text{HCl}6\text{aq}$ extremely thin needles, appearing like a jelly when in mass, v sl boiling water— $\text{B}^+\text{H}_2\text{PtCl}_62\text{aq}$ lemon yellow crystalline powder, insol water, alcohol, and HCl aq

LANUGINIC ACID $\text{C}_{41}\text{H}_{64}\text{O}_6$, H 73 p.c., N 163 p.c., S 34 p.c., O 314 p.c. An acid produced by the action of boiling baryta water upon wool (Champion, *C R* 72, 330, Knecht & Appleyard, *J* 22, 1120) The excess of baryta is removed by CO_2 , the acid pptd by lead acetate, and the pp decomposed by H_2S Yellowish porous mass, v sol hot water, sl sol alcohol, insol ether Its aqueous solution ppts colouring matters as lakes It also ppts tannin and most metallic oxides from their acetates It reacts like a proteid with Millon's reagent and with phosphotungstic acid

LAPACHIC ACID $\text{C}_{11}\text{H}_{14}\text{O}_5$, α $\text{C}_{11}\text{H}_{13}\text{O}_5(\text{OH})\text{CH}^+\text{Pr}$ *Oxy-amenyl naphthogumone* *Targuine* [138°]

Occurrence—A yellow colouring matter present in the 'lapacho' wood of a genus of the Bignonaceae, several species of which are indigenous to the Argentine Republic and other parts of South America (Siewert, *Report of Argentine Republic*, cap 15, *Philadelphia*). Occurs

also in Greenheart from Surinam (Stein, *J pr* 99, 8), and in Bethabarra wood (Greene & Hooker, *Am* 11, 267)

Preparation—The wood (10 kilos), in the form of saw dust, is boiled with a moderately-concentrated solution of sodium carbonate (500 grms crystallised salt in 80 litres water), the extraction is repeated several times The solution is of a blood red colour, and the addition of hydrochloric acid precipitates the crude acid together with a red brown resin, from which it is best purified by frequent solution and recrystallisations from benzene (Paternò, *G* 9, 505, 12, 337, Arnaudon, *C R* 46, 1152) Yield 5 p.c. of pure material

Properties—Monoclinic prisms, $\alpha b c = 7206 \cdot 1 \quad 6492$, $n = 97 \cdot 9$ (Panebianco, *G* 10, 80), v sol boiling alcohol, benzene, and ether It dissolves readily in solutions of the alkalis and alkaline earths, forming red solutions containing salts of the acid It decomposes carbonates on boiling

Reactions—1 Completely oxidised by *chromic acid*—2 Alkaline KMnO_4 gives oxalic acid—3 Boiling *nitric acid* (*S G* 138) yields phthalic acid—4 Distillation with *zinc-dust* yields isobutylene, naphthalene, and possibly a homologue of naphthalene—5 Boiling with HIAq and phosphorus forms amyl naphthalene (305°) and a little di (β)-naphthyl, both being perhaps derived from an intermediate naphthyl amylene 6 Cold conc HNO_3 (*S G* 149) or H_2SO_4 gives lapachone—7 *Zinc-dust* and *potash* reduce it to an unstable crystalline hydride, re-oxidised by air to lapachic acid

Salts— $\text{NaA}'5\text{aq}$ scarlet radio-crystalline mass S (of NaA') 151 at 24° Sol alcohol— $\text{KA}'\text{S}$ 333 at 24°— $\text{NH}_4\text{A}'\text{aq}$ large brick red crystals— $\text{CaA}'_2\text{aq}$ amorphous red pp S 224 at 24°— $\text{BaA}'_2\text{aq}$ long slender needles (from boiling water) S 23 at 26°— $\text{SrA}'_2\text{aq}$ — PbA'_2 , amorphous red pp, insol water— AgA' scarlet powder—Aniline salt $\text{C}_{11}\text{H}_9\text{NH}_2\text{A}'$ [123°], orange prisms (from alcohol)— α -Toluidine salt $\text{C}_{11}\text{H}_9\text{MeNH}_2\text{A}'$ [135°], yellow laminae— p -Toluidine salt [130°], orange yellow laminae

Acetyl derivative $\text{C}_{11}\text{H}_{12}\text{AcO}_5$ [83°] Formed, together with a compound $\text{C}_{11}\text{H}_{11}\text{O}_5$ (?), by heating lapachic acid with NaOAc and Ac_2O (Paternò) Sulphur yellow prisms, insol water, sol alcohol, ether, and benzene Readily converted by potash into lapachic acid Br in HOAc converts it into bromo lapachone HNO_3 (*S G* 148) at 0° forms a nitro-compound $\text{C}_{11}\text{H}_{12}(\text{NO}_2)\text{AcO}_5$ [170°], crystallising in reddish plates The compound $\text{C}_{11}\text{H}_{11}\text{O}_5$ forms small white acicular prisms [132°], v sl sol cold alcohol and ether Boiling alcoholic KOH does not saponify it, but converts it into a compound $\text{C}_{11}\text{H}_{12}\text{O}_5$, which crystallises (from alcohol) in orange needles [141°] Br does not convert the compound $\text{C}_{11}\text{H}_{11}\text{O}_5$ into bromo lapachone

Bromo-lapachone $\text{C}_{11}\text{H}_{11}\text{BrO}_5$ α

$\text{C}_{11}\text{H}_{12}\text{O}_5 < \frac{\text{CHBr}}{\text{O}} > \text{CHPr}$ (?) [140°] Formed by

warming lapachic acid with Br in HOAc (Paternò, *G* 12, 353) Orange laminae, v sol Lot alcohol, sol HOAc, and benzene, sl sol ether, insol cold aqueous alkalis HNO_3 oxidises it to phthalic acid.

Lapachone $C_{12}H_{10}O_4$, *see*

$C_{12}H_{10}O_4 < \begin{smallmatrix} OH \\ | \end{smallmatrix} > CHPr (?)$ [156°] Formed by the action of H_2SO_4 or cold conc HNO_3 (SG 149) on lapachic acid (Paternò, *G* 12, 837, Hooker & Greene, *B* 22, 1723) Silky orange red needles (from alcohol), insol water, v sol hot alcohol and benzene HNO_3 oxidises it to phthalic acid Distillation over red hot zinc dust gives naphthalene and isobutylene Ac_2O has no action Boiling with $NaOAc$ and Ac_2O forms a compound $C_{22}H_{22}O_4$, crystallising in brown tables with blue reflex, nearly insol Ac_2O $NaHSO_4$ forms a white crystalline compound Combines readily with hydroxylamine and with NH_3 Its molecular weight, found by Raoult's method, agrees with the formula $C_{12}H_{10}O_4$ Lapachone is converted by heating with alkalis into $C_{10}H_8O_4(OH)CH_2CH(OH)Pr$, which separates from cold alcohol or $HOAc$ in large crystals [125°], v sol most solvents, readily converted into lapachone by dilute HCl , and forming the salts $BaA''aq$ and $AgA''aq$, both crystallising in red needles

LARCH FUNGUS This fungus extracted with 95 p c alcohol yields a mixture of at least four different resins (Masing, *Ar Ph* [3] 6, 111)

(a) $C_{12}H_{12}O_4$ [125°] S (95 p c alcohol) 3 at 14° Insol chloroform

(b) $C_{12}H_{10}O$ [90°] S (95 p c alcohol) 7 Sol chloroform

(c) $C_{12}H_{10}O_4$ Agaric acid. [272°] Needles, v sl sol boiling alcohol, insol chloroform (Jahns, *Ar Ph* 221, 269)

(d) A portion easily soluble in alcohol, and partly ppd by water, leaving in solution a resin [C 61.9 p c, H 8.1 p c, O 30.0 p c] S 17, S (alcohol) 17 The resinous mixture is altered by boiling with milk of lime, the pp then thrown down by HCl being separated by chloroform into two substances $C_{12}H_{10}O_4$, insol chloroform, S (alcohol) 6, and $C_{12}H_{12}O_4$, sol chloroform, S (alcohol) 21

LARDACEIN v PROTEINS

LARD OIL A nearly colourless fatty oil, obtained by pressing hog's lard SG 20° 9122, d_4^{20} 1.4686 (Long, *Am* 10, 392)

LARICIC ACID $C_{16}H_{16}O_4$ [153°] S 1.14 at 60° Obtained from the small branches of larch trees (*Pinus larix*) from 20 to 30 years old (Stenhouse, *Pr* 11, 405) The bark is exhausted with water at 80°, and the extract evaporated and distilled The distillate is evaporated at 80° and the resulting crystals purified by sublimation Long monoclinic crystals resembling benzoic acid, usually in twins Sublimes at 93° Volatile with steam Has a bitter astringent taste and powerful odour Reddens litmus slightly M sol boiling water and alcohol, insol ether Nitric acid oxidises it to oxalic acid Its aqueous solution is ppd by baryta water, but not by lead or silver salts Ferric chloride gives a purple-red colour The K salt forms flat reddish brown crystals, decomposed by CO_2

LARREA RESIN Occurs on branches of *Larrea mexicana* (Stillmann, *B* 13, 756) 61.7 p c of it dissolves in alcohol, 26.3 in aqueous potash, and 1.4 p c consists of a colouring matter soluble in water

LASERPITIN $C_{22}H_{22}O_4$ (Feldmann, *A* 135, 886; *B* 1866, 1.457) or $C_{12}H_{22}O_4$ (Kütz, *Ar Ph*

[3] 21, 161) [114°] (F); [118°] (K) A bitter principle contained in the root of *Laserpitium latifolium* Extracted by 80 p c alcohol (F) or by light petroleum (K) Prisms Insol water, sol benzene, chloroform, ether, and CS_2 May be sublimed Its alcoholic solution is ppd by water, but not by alcoholic lead acetate (F) Insol dilute acids and alkalis Conc H_2SO_4 and conc $HClAq$ form deep red solutions (K) When heated with conc alcoholic KOH it is resolved into angelic acid and laserin $C_{11}H_{12}O_4$ (F) or $C_{22}H_{22}O_4$ (K), a crystalline resin, insol acids, sol ether, alcohol chloroform, and $HOAc$ Potash fusion gives methyl crotonic acid and laserin (K)

Laserpitin forms an acetate $C_{13}H_{22}O_4HOAc$ crystallising from acetic acid in silky needles (K)

Acetyl derivative $C_{13}H_{21}AcO_4$ [113°] From laserpitin, Ac_2O , and dry $NaOAc$ (K) Colourless needles, insol water, sol $HOAc$, alcohol, ether, and $CHCl_3$

Bromo derivative $C_{20}H_{20}Br_2O_4$ [90°] Formed by the action of Br on a solution of laserpitin in $CHCl_3$ (K) Needles, sol alcohol, ether, $CHCl_3$, and $HOAc$

Di-nitro- derivative $C_{13}H_{20}(NO_2)_2O_4aq$ [115°] From laserpitin and HNO_3 (K) Amorphous mass, insol water, sol alcohol, ether, $CHCl_3$, and $HOAc$

LAUDANINE $C_{20}H_{27}NO_3$ (Hesse, *A* 153, 57, 176, 201, *Suppl* 8, 272) [165°] SG 1.256 (Schröder, *B* 13, 1075) S (ether) 155 at 18° [α] = -13.5 in a 2 p c chloroform solution at 22.5°

Preparation—An aqueous extract of opium is ppd by lime or Na_2CO_3 , the filtrate is shaken with ether, the ethereal solution is shaken with dilute acetic acid, the acetic acid solution is neutralised exactly with NH_3 , the ppd lanthopine is removed by filtration, the filtrate is ppd by excess of ammonia, and the pp crystalised from ether Laudanine separates first from the ethereal solution, and afterwards codamine. The laudanine is dissolved in acetic acid solution, and the solution mixed with excess of $NaOH$, which ppt's cryptopine The alkaline filtrate is ppd by ammonium chloride, and the pp dissolved in aqueous $HOAc$, on adding KI laudanine hydro iodide is ppd, and this is decomposed by ammonia and the free base crystallised from ammonia

Properties—Stellate groups of small six-sided prisms (from alcohol) Cannot be sublimed Tasteless Lævorotatory In the crystalline state it is v sol benzene, $CHCl_3$, and boiling alcohol, sl sol cold alcohol, v sl sol ether In the amorphous state it is much more soluble Its salts have a bitter taste From their solutions caustic potash and ammonia ppt the base in white amorphous flocks, which soon become crystalline, and dissolve in excess of the precipitant Chloroform extracts the base from the ammoniacal but not from the potash solution Conc H_2SO_4 (containing ferric salt) gives an intense rose red solution, which at 150° changes to dark violet Conc HNO_3 gives an orange-red solution $FeCl_3$ gives an emerald-green colour The base is poisonous, its hydrochloride acting physiologically like strychnine.

Salts— B, H_2SO_4, aq concentric groups of

needles, v e sol water, almost insol dilute H_2SO_4 .—B'HC1 6aq prisms, v sol water and alcohol, v sl sol NaClAq Inactive to light—B'HB'r 2aq nodules S 35 at 20°—B'HI aq crystalline powder S 2 at 15° v sol boiling water, insol KIAq—B' H_2PtCl_6 2aq yellow amorphous pp, v sol boiling water—B' $H_2C_2O_4$ 6aq concentric groups of delicate needles [110°] S 22 at 10°—B' $C_4H_9O_3$ 3aq [100°] S 49 at 15°

LAUDANOSINE $C_{21}H_{33}NO_4$ [89°] S (ether) 52 at 16° $[\alpha]_D^{20} = 105$ in a 2 p c alcoholic solution at 22 5° $n_D^{20} = 56$ in a 2 p c chloroform solution at 22 5°

Preparation—Obtained from opium by ppg the aqueous extract with Na_2CO_3 , dissolving the pp in ether, shaking the ethereal solution with dilute HOAc, and pouring the acid solution into aqueous NaOH The pp contains a large number of bases, and is warmed with alcohol and dilute HOAc, and partially evaporated at 50° Papaverine and narcotine are then ppd, and thebaine and tartrate is ppd by adding tartaric acid to the filtrate The filtrate is exactly neutralised with NH_3 , and $NaHCO_3$ added After a week the pp is collected and extracted with benzene Cryptopine and protopine separate first from the benzene, and when the filtrate is shaken with $NaHCO_3$, laudanosome separates (Hesse, *A Suppl* 8, 321) It is purified by dissolving in acetic acid, ppg with KI, decomposing the resulting salt with NH_3 , and recrystallising from benzene

Properties—Needles More soluble in ether than thebaine and cryptopine, extremely sol alcohol and chloroform, v sol boiling benzene and ligroin, insol water and alkalis Conc H_2SO_4 (containing ferric salt) gives a brownish red solution, which at 150° becomes green, and finally dark greenish violet $FeCl_3$ gives no colour Tastes slightly bitter, its salts have an extremely bitter taste Its alcoholic solution exhibits a strong alkaline reaction Dextro rotatory Its hydrochloride is also dextro rotatory, $[\alpha]_D^{20} = 108$ in a 2 p c solution at 22 5°

Salts—B'HI aq small prisms, v sl sol cold water, v sol alcohol—B' H_2PtCl_6 3aq yellow amorphous pp, insol cold water—B' $H_2C_2O_4$ 3aq prisms, v e sol water

LAUREL OILS The essential oil from the leaves of the common cherry laurel (*Cerasus laurocerasus*) consists of benzoic aldehyde, HCy, a volatile oil (possibly benzyl alcohol) convertible by oxidation into benzoic acid, and minute quantities of an odorous resin (Elden, *Ph* [3] 5, 761, cf Leger, *Ph* [3] 3, 971) The essential oil from the fruits of *Laurus nobilis* contains a levorotatory terpene $C_{15}H_{26}$ (164°), SG 15 908, a levorotatory sesquiterpene $C_{15}H_{22}$ (250°), SG 15 925, and lauric acid $C_{12}H_{24}O_2$ (Blas, A 134, 1, Gladstone, *C J* 17, 1) The essential oil from the leaves of the Californian laurel (*Oreodaphne californica*) contains terpineol (168°) and umbellol $C_8H_{10}O$ (216°) (Stillmann, *B* 13, 629)

Laurel-nut oil is a fatty oil, SG 932, derived from *Calophyllum inophyllum* growing in the East (Hooper, *Ph* [3] 19, 525)

LAURENE v DI METHYL-ETHYL-BENZENE

LAURIC ACID $C_{12}H_{24}O_2$ Dodecic acid Mol. w. 200 [43 6°] (Heintz) (225°) at 100 mm.

(Krafft, *B* 13, 1415) SG 22 883 (Görgey). H C 1759730 (Lougumme, *A Ch* [6] 11, 222) Occurs as glyceryl ether in the berries of the bay tree (*Laurus nobilis*) (Marsson, *A Ch* 41, 33, Blas, A 134, 1), in the fat of pichurum beans (Schamer, *A* 53, 393), in the volatile oil of these beans (Müller, *J pr* 58, 469), in small quantity in spermaceti (Heintz, *A* 92, 394), in croton oil (Schlippe, *A* 105, 14), in the fruit of *Cylco daphne sebifera* (Gorkom, *Tydschrift af neerl Indie*, 81, 410), in the so called Dika bread, the fruit of *Mangifera gabonensis* (Oudemans, *J pr* 81, 356), in the age of the Mexicans, a fat obtained from *Coccus Azza* (Hoppe, *J pr* 80, 102), and in cocoa nut oil (Görgey, *A* 66, 303)

According to Scherring (*A* 96, 236) it is among the products of the distillation of cetyl alcohol with potash-lime, but Heintz (*A* 97, 271) denies this A dodecic acid [35°], isomeric with lauric acid, may be obtained by treating the amide of myristic acid with Br and NaOH, and converting the resulting dodecylamine into the nitrile and thence into the amide [97°] of dodecic acid, and boiling the amide with conc HClAq (Lutz, *B* 19, 1433)

Preparation—Lauric acid may be obtained from fats containing it by saponification followed by fractional precipitation of the acids by barium acetate (Heintz, *A* 92, 294, *P* 92, 429, 583, *J pr* 66, 1) It may also be obtained from the fat of bay berries by saponifying, distilling the solid fatty acids under reduced pressure, and rectifying *in vacuo* (Krafft, *B* 12, 1665)

Properties—Silky needles united in tufts (from alcohol) or scaly crystalline mass (after fusion) Its alcoholic solution has a slight acid reaction It is slightly volatile with steam Insol water, v sol alcohol and ether. Gives diennyl ketone ($C_{11}H_{22}O$) when its calcium salt is distilled

Salts—KA' Amorphous S (alcohol) 45 at 15°, 38 at 78° (Oudemans, *C C* 1863, 737)—KHA' Crystalline S (alcohol) 15 at 15°; 400 at 78°—NaA' White powder S (alcohol) 25 at 15°, 145 at 78°—NaHA' S (alcohol) 2 at 15°—NH₄HA' S (alcohol) 6 at 15°—BaA' crystalline spangles (from alcohol) S 07 at 100°, 0054 at 15° (Oudemans), 009 at 17°, 50 at 100° (Görgey) S (alcohol) 0187 at 15°, 1009 at 78° (O), 07 in the cold, 5 at 78° (G)—CaA' aq S 0039 at 15°, 0547 at 100° S (alcohol) 0719 at 15°, 220 at 78° (O)—SrA' aq S 0272 at 15°, 036 at 100° S (alcohol) 96 at 15°, 36 at 78°—MgA' 3aq S 023 at 15°—PbA' [110°–120°] (Heintz) S 0011 at 100° S (alcohol) 0047 at 15°, 235 at 100°—CoA' aq—NiA' aq—NiA' 3aq—CuA' S 0023 at 15°, 0029 at 100°—AgA' white powder, consisting of minute slender needles S 0001 at 15°, 0405 at 100° S (alcohol) 0323 at 15°, 0824 at 78°

Ethyl ether EtA' [–10°] (269°) at 750 mm (Delfs, *A* 92, 278) SG 22 86 (Görgey) V D 84 (calc 79) From the acid, alcohol, and HCl

Glyceryl ether $C_3H_7(C_{12}H_{25}O_2)_3$ (Schiff, *B* 7, 781) *Trilaurin Lauratearin* [45°] H. C. 5707420 (Lougumme, *A Ch* [6] 11, 222). Obtained from bay berries by extracting with alco-

hol Silky needles, sl sol cold alcohol, v sol ether

Phenyl ether $\text{A}'\text{C}_6\text{H}_5$, [24½°], (210° at 15 mm), pearly plates

p-Tolyl ether $\text{A}'\text{C}_6\text{H}_4$, [28°], (220° at 15 mm) (Krafft a Burger, B 17, 1878)

Amide $\text{C}_{11}\text{H}_{23}\text{CONH}_2$, [102°] (Krafft a Stauffer, B 15, 1729) From the chloride and NH_3

Chloride $\text{C}_{11}\text{H}_{23}\text{COCl}$ [-17°] (142½° at 15 mm) Colourless liquid (Krafft, B 17, 1878)

Nitrile $\text{C}_{11}\text{H}_{23}\text{CN}$ [4°] (198° at 100 mm) S G $\frac{1}{4} = 835$, $\frac{1}{2} = 827$, $\frac{100}{100} = 767$ Formed by distilling lauramide with P_2O_5 (Krafft a Stauffer, B 15, 1729) Colourless liquid of peculiar odour

LAURIC ALDEHYDE $\text{C}_{11}\text{H}_{23}\text{CHO}$ [45°] (143° at 22 mm) Prepared by the dry distillation of a mixture of calcium laurate and formate (Krafft, B 18, 1414) White crystalline odourless solid

LAURIN $\text{C}_{12}\text{H}_{24}\text{O}_2$ Bay berry camphor A substance discovered by Bonastre (*J Ph* 10, 32) in the berries of the bay tree, and further examined by Marsson (A 41, 329) and Delffs (A 88, 354) It is prepared by boiling the skinned and pounded berries with alcohol of 85 to 90 p.c., filtering at the boiling heat, and leaving the liquid to itself for several days Lauric stearin is then first deposited, and on filtering again and leaving the liquid to evaporate, laurin is deposited in crystals contaminated with a viscid oil, from which they may be freed by pressure between paper and recrystallisation Dimetric crystals, destitute of taste and smell, insol water, v sol alcohol, even in the cold, sol ether The solutions are neutral to test papers Laurin does not dissolve in alkalis Laurin can not be distilled without decomposition Its alcoholic solution is not precipitated by acetate of lead or nitrate of silver

LAUROCERASIN A name given by Lehmann (*N R P* 23, 440) to amygdalin when extracted from the leaves of the cherry laurel (*Cerasus laurocerasus*) or the bark of the berry-bearing alder (*Rhamnus Frangula*), v AMYGDALIN

LAURONE $\text{C}_{23}\text{H}_{46}\text{O}$ i.e. $(\text{C}_{11}\text{H}_{23})_2\text{CO}$ Di-*enyl ketone* [69°] S G, $\frac{1}{4} = 802$, $\frac{100}{100} = 788$ Formed by distilling barium laurate with lime Shining plates (from alcohol) On reduction it gives tricosane (Overbeck, P 86, 591, A 84, 289, Krafft, B 15, 1712)

LAURONOLIC ACID $\text{C}_6\text{H}_{11}\text{O}_2$ i.e. $\text{C}_6\text{H}_9\text{CO}_2\text{H}$ Formed by distilling camphanic acid, or by heating its barium salt with water at 200°, campholactone is formed at the same time (Woringer, A 227, 7)

Properties—Oil Sol water and ether Volatile with steam In presence of HCl some of it changes into the isomeric campholactone When distilled with water, a great part changes to the campholactone

Salts— CaA' , 3aq Forms dendritic crystals on the surface of an evaporating solution— AgA'

LAUROSTEARIN v *Glyceryl ether of LAURIC ACID*

LAUROXYLIC ACID v. DI METHYL BENZOIC ACID.

LAUTH'S VIOLET v AMIDO IMIDO IMIDO DI PHENYL SULPHIDE

LAVENDER OIL A volatile oil obtained by distilling the flowers of *Lavendula officinalis* with steam S G 12 875 It contains a levorotatory terpene $\text{C}_{10}\text{H}_{18}$ (162°) which forms a crystalline hydrochloride and various oxygenated bodies which yield camphor on further oxidation (Dumas, A Ch 13, 775, Lallemand, A 114, 198, Barth, Z 1867, 509, Bruylants, J Ph [4] 30, 39) English oil of lavender submitted to fractional distillation yields 30 p.c. of the terpene (176°-186°), and 30 p.c. of oxygenated products (200°-207°) (Shenstone, Ph [2] 13, 207)

LEAD Pb At w 206.4 Mc° w not known with certainty, but probably same as w (v. p 124) [330°-335°] (Brigel, B 6, 191, Pictet, P M [5] 7, 446), [326°] (Riemsdyk, C N 20, 32, Person, J 1849) (Between 140° and 1600°) (Carnelley a Williams, C J 35, 565) S G 11 335 at 0° (Quincke, P 97, 396), 11 37 at 0° (Reich, J pr 78, 328), 11 345 to 11 358 at 4°, 11 352 to 11 366 at 23° (Schweitzer, Am Ch 7, 174) S G molten 10 37-10 65 (Roberts a Wrightson, A Ch [5] 30, 181) For other values for S G v Clarke's *Table of Spec Gravities* [1888], pp 5-6 S H -78° to 11° 03065 (Regnault, A Ch [3] 26, 286), S H 19° to 48° 0315 (Kopp, Tr 1865 71), S H molten 340° to 450° 0402 (Person, A Ch [3] 24, 129) C E 0° to 100° 00002799 (Matthiessen, Pr 15, 220) T C (Ag=100) 8.5 (Wiedemann a Franz, P M [4] 7, 33) Heat of fusion 5858 (Rudberg, P 19, 125), 5369 (Person, A Ch [3] 24, 129) E C (Hg at 0°=1) 4.8 at 0°, 3.363 at 100° (Lorenz, W 13, 422, 582) Crystallises in regular octahedra For emission spectrum of lead v Werther, J pr 88, 180, Cornu, C R 73, 332, L de Boisbaudran, C R 77, 1152, Hartley a Adeney, Tr 1884 63

Occurrence—Lead occurs native in small quantities (e.g. v Chapman, P M [4] 31, 176, Koksharov, J M 1875 873, Igelstrom, J M 1889 (ii) 32) *Galena* (PbS) is very widely distributed, the other most important ores of lead are *cerussite* (carbonate), *anglesite* (sulphate), *pyromorphite* (phosphate), and *mimetesite* (arsenate) Small quantities of oxychloride, chromate, molybdate, tungstate, vanadate, &c., of Pb also occur Lead has been known and used from very early times

Formation—1 PbS is roasted in a reverberatory furnace until a portion is oxidised partly to PbO and partly to PbSO₄, the doors are then closed, and the PbS, PbO, and PbSO₄ react to produce SO₂ and Pb, PbS + 2PbO = 3Pb + SO₂, PbS + PbSO₄ = 2Pb + 2SO₂, -2 PbS is roasted in a reverberatory furnace, the temperature being gradually increased until a considerable quantity of PbSO₄ and a little PbO are produced, the doors are then closed, and the temperature is raised until the mass softens but does not melt When the PbS and PbSO₄ react to produce Pb and SO₂, the residue is again roasted, whereby more PbSO₄ is formed, and on raising the temperature with closed doors the PbSO₄ and PbS react as before After a time the quantity of PbSO₄ relatively to PbS becomes so great that the chief product of their reaction is PbO (PbS + 3PbSO₄ = 4PbO + 4SO₂), coal and wood are then thrown into the furnace, and heating is

continued, when the PbO is reduced to $\text{Pb}(\text{PbO} + \text{C} = \text{Pb} + \text{CO})$, at the same time some of the PbSO_4 is partly reduced to PbS , which, reacting with the remaining PbSO_4 , produces Pb and SO_2 ($2\text{PbSO}_4 + 2\text{C} = \text{PbSO}_4 + \text{PbS} + 2\text{CO}_2$) — 3 PbS is melted with scrap Fe , $\text{PbS} + \text{Fe} = \text{FeS} + \text{Pb}$ — 4 PbCO_3 is strongly heated with C , $\text{PbCO}_3 + 2\text{C} = \text{Pb} + 3\text{CO}$ — 5 PbO is reduced by heating in H or CO , or with C , KCN , or Na — 6 Zinc is suspended in an acidulated solution of a Pb salt, when Pb is ppt on the zinc — 7 PbCl_2 is mixed with Na_2CO_3 , and heated with KCN or C

Preparation — 1 By melting Pb prepared by one of the foregoing methods, exposing the molten mass to a gentle current of air, blowing water vapour through the mass, and running off the metal from beneath the film of oxides of Cu , Sb , Fe , &c., nearly pure Pb is obtained — 2 Pb oxalate is strongly heated in a carbon crucible, or is mixed with powdered C and heated — 3 Stas prepared pure lead by the following process (*Chem. Propriétés* 324) Commercial Pb acetate was dissolved in water, and digested at 40° to 50° in a leaden vessel with sheets of Pb until all Cu and Ag were ppt , the filtered liquid was run into almost boiling water, strongly acidulated with H_2SO_4 , the ppt PbSO_4 was very thoroughly washed, and then suspended in a solution of NH_4 sesquicarbonate and NH_3 until transformed into PbCO_3 , the PbCO_3 was thoroughly washed, a part of it was decomposed to PbO by heating in a Pt dish, and the rest was almost, but not quite, entirely dissolved in dilute HNO_3Aq , the solution of $\text{Pb}(\text{NO}_3)_2$ was heated to boiling, and the PbO was added little by little, the last traces of Fe were thus ppt as oxide, the boiling liquid was filtered and poured into solution of NH_4 sesquicarbonate. In this way pure PbCO_3 was obtained. The PbCO_3 was dried, and added little by little to pure molten KCN contained in an unglazed porcelain crucible placed within a larger crucible, the space between being filled with powdered Al_2O_3 , previously heated and mixed with 5 p.c. melted and powdered borax. The Pb thus obtained was again placed in pure molten KCN , and kept there until the upper surface of the Pb appeared convex and lustrous like pure Hg , after partial cooling the Pb was run off into a mould of polished steel. If a trace of PbO or PbS is present in the molten Pb the surface does not become convex.

Properties — Almost white, lustrous metal. Ordinary lead is blue gray, it contains traces of Ag , Cu , Sb , and sometimes Fe and Mn . Very malleable and ductile, but the properties are greatly affected by small quantities of impurities, notably by PbO , which is somewhat soluble in molten Pb . Tenacity very low. Somewhat sonorous. Leaves a mark on paper. Lead is so soft that it can be cut by a knife or scratched by the nail, traces of foreign metals, or of As or S , increase the hardness of Pb . By slowly cooling molten Pb , piercing a hole in the crust by an iron rod, and pouring off the still molten portion, the metal is obtained in regular octahedra often aggregated together similarly to crystals of NH_4Cl (Marx, *S* 57, 193, Stolba, *D P J*, 364, 371). Crystals of Pb are also obtained by hanging a rod of zinc in a slightly acidulated solution of a Pb salt, or by passing an electric current through

such a solution. Pb vaporises at high temperatures (1400° – 1600°), the vapour is very poisonous. The lustrous surface of Pb quickly tarnishes in ordinary air from formation of a film of oxide (probably Pb_2O). Very finely divided Pb is quickly changed to the suboxide Pb_2O , such finely divided Pb may be obtained by covering a Zn plate with a little PbSO_4 , made into a paste with water, laying another Zn plate on the top, and placing the whole in NaClAq for 9 or 10 days (*v* Bolley, *Ph C* 1850 59). Pb is readily changed to PbO on the surface by melting in air. Pb is not changed in dry air, nor when kept under pure water from which all air has been removed, in contact with water and the atmosphere it becomes gradually covered with a white deposit of 2PbCO_3 , $\text{PbO.H}_2\text{O}$, and small quantities of a soluble Pb salt are also formed (*v* *Reactions*, No 2). Pb is soluble in HNO_3Aq , and is slowly changed to PbCl_2 by the action of HClAq in the air, hot conc. H_2SO_4 forms PbSO_4 , Pb is oxidised by heating with KNO_3 or KHSO_4 . Combines with the halogens, also with S , Se , P , and As , forms alloys with many metals.

The atomic weight of Pb has been determined (1) by finding V D of PbCl_2 (Roscoe, *Pr* 27, 426), and analyses of this compound (Marignac, *Ar Sc* 1, 59, 209, Dumas, *A Ch* [3] 55, 196), (2) by syntheses of $\text{Pb}(\text{NO}_3)_2$ and PbSO_4 (Stas, *Rech* 101, *Chem. Propriétés* 329), (3) by converting Pb , PbO , and PbS into PbSO_4 , and by analysing PbCO_3 (Berzelius, *P* 8, 15, *G A* 37, 259, 265, Turner, *A* 13, 17), (4) by determining SH of Pb (Regnault, *A Ch* [3] 26, 286).

Lead is metallic in its chemical behaviour. The oxide PbO is strongly basic, it is slightly soluble in water, and the solution turns red litmus blue and absorbs CO_2 from the air, it decomposes hot solutions of NH_4 salts with evolution of NH_3 , and it reacts with acids to form salts PbX_2 ($\text{X} = \text{NO}_3$, $\frac{1}{2}\text{SO}_4$, &c.), PbCO_3 is isomorphous with the carbonates of the alkaline earths, on the other hand, PbO dissolves in fairly conc. KOH Aq , probably forming a salt PbO.K_2 , and compounds of PbO with CaO and Ag_2O are known. PbO_2 reacts with strong bases, e.g. KOH , to form unstable salts, e.g. K_2PbO_3 , on the other hand, treatment of Pb_2O_3 with conc. $\text{H}_3\text{PO}_4\text{Aq}$ or $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$ produces solutions which react as if they contained salts of PbO_2 . The greater number of the lead salts correspond with the oxide PbO , $\text{Pb}(\text{CH}_3)_4$, however, is stable as a gas.

Lead is placed in Series II of Group IV, the other odd series members of this group are Si , Ge , and Sn . Pb more nearly resembles Sn than any other member of Group IV, it is more distinctly metallic than the other elements of the group, the other elements of this group form several compounds MX_4 , whereas most of the Pb compounds belong to the form MX_2 . Pb forms many basic and several double salts (*cf* CARBON GROUP OF ELEMENTS, vol 1 p 684, also TIN GROUP OF ELEMENTS, in vol iv). In its physical properties Pb resembles Tl , one series of Tl salts, however, is similar to those of the alkali metals, and the other series resembles those of the earth metals (*v* EARTH METALS OF THE, vol u p 424). The atom of Pb is divalent in the gaseous molecule PbCl_2 , and tetravalent in the gaseous molecule $\text{Pb}(\text{CH}_3)_4$.

Ramsay (*C J* 55, 521) has determined the lowering of vapour pressure of Hg produced by dissolving Pb in Hg, the results obtained make it probable that the molecular weight of lead is the same as the atomic weight, this result assumes the accuracy of Van't Hoff's law, that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved substances, and it also regards the molecular weight of liquid Hg as the same as the atomic weight

Reactions—1 Unchanged in dry air, superficially oxidised (probably to Pb₂O) in moist air, oxidised to PbO by heating in air or oxygen—2 Water quite free from air has no action on Pb at ordinary temperatures (Stalman, *D P J* 180, 366, Bottger, *J* 1866 232, but *v* Muller, *J pr* [2] 36, 317) Water and air together dissolve a little Pb, and at the same time a deposit of 2PbCO₃, Pb(OH)₂ is formed Water charged with CO₂ under a pressure of a few atmospheres dissolves considerable quantities of Pb (perhaps in the form of an acid carbonate) The presence of small quantities of nitrates, especially NH₄NO₃, of soluble alkaline chlorides, and of some other salts, *eg* (NH₄)₂SO₄, increases the solvent action of water on Pb, the amount of Pb in solution is greater after a few days' action than after many days' exposure to the air In these reactions the soluble salt of Pb is probably slowly acted on by the CO₂ of the air with formation and ppn of insoluble 2PbCO₃, Pb(OH)₂ The presence of alkaline carbonates or of a little Ca silicate in water almost wholly stops the solvent action on Pb, probably the insoluble hydrocarbonate is formed as quickly as Pb is dissolved The action of water on lead has been examined by Graham, Miller, a Hofmann, Noad (*C J* 4, 20), Yorke (*P M* [3] 5, 82), Dumas (*C R* 77, 1054), Berthelot (*C R* 77, 1063), Pattison Muir (*C N* 25, 294, 33, 102, 125, 145, 34, 223, 234, 35, 82, 110, *C J* 31, 660), Muller (*J pr* [2] 36, 317), Carnelley a Frew (*S C I* 7, 15, 78), and others Granulated lead slowly decomposes boiling water, evolving H (Stolba, *J pr* 94, 113)—3 Lead is dissolved by several acids, slowly by hot conc HClAq in contact with air, also slowly by conc H₂SO₄ (Calvert a Johnson, *C J* 16, 66), rapidly by HNO₃Aq For account of gaseous products of reaction with HNO₃Aq *v* Ackworth a Armstrong, *C J* 82, 54.

Technical applications of lead—Lead is largely used for vessels and apparatus in which different chemical processes are conducted, *eg* for sulphuric acid chambers, water pipes are usually made of lead Alloys of lead with tin form solder and pewter, an alloy with As is used for making shot, an alloy with Sb is used as type-metal, and emery wheels and grinding tools used by lapidaries are made of an alloy of Pb and Sb, alloys of Pb with Sn and Bi have low melting-points Lead oxide, chromate, acetate, and carbonate are all largely used in manufactures

Detection and Estimation—HClAq ppts white PbCl₂ from solutions of Pb salts, sl sol cold water, fairly sol hot water, nearly insol dilute HClAq Dilute H₂SO₄, or a soluble sulphate, ppts white PbSO₄, almost insol dilute H₂SO₄Aq, quite insol alcohol. K₂CrO₄Aq ppts

yellow PbCrO₄, insol water KIAq ppts yellow PbI₂, sol boiling water, but reppd in yellow crystalline spangles on cooling H₂S ppts brownish black PbS, insol dilute acids, alkalis, or alkaline sulphides, presence of much HCl prevents ppn from rather dilute solutions of salts of lead, in presence of a little HCl pp is sometimes red or yellow red, and consists of xPbS yPbCl₂ (*v* Lead sulphochloride of) The H₂S test is said to detect 1 pt of lead in 100,000 pts of water, the H₂SO₄ test 1 pt in 20,000, and the K₂CrO₄ test 1 pt in 70,000 Pb may be estimated as Pb₂O, by ppn with dilute H₂SO₄Aq adding about 2 vols of alcohol, washing with alcohol, drying and calcining

Supposed allotropic form of lead When lead is deposited on the negative electrode by passing a current through a neutral or acid solution of a lead salt, and the current is continued for some hours, the lead becomes the colour of copper (Wohler, *A Suppl* 2, 135) After washing the red leaflets thus obtained with water and alcohol, they retain their colour on exposure to the air, and are not acted on by dilute HClAq or cold dilute HNO₃Aq, or alkalis, but are readily dissolved by hot HNO₃Aq, heated in H they melt above 200° and become ordinary lead Wöhler regarded the red substance either as an allotypic form of lead, or as a hydride of lead, Stolba (*J pr* 94, 113) suggested that the red colour was due to a film of oxide on the surface of the lead (*v* also Schutzenberger, *C R* 86, 1265)

Lead, alloys of Lead alloys with many metals, the alloys are produced by fusing together the constituent metals, some of them are definite compounds, in these cases either of the constituents is generally soluble in the compound

Alloys with bismuth, and with bismuth and other metals Pb and Bi may be alloyed in all proportions, malleability is diminished by adding more than an equal weight of Bi By fusing together 70 p c Pb, 15 p c Bi, and 15 p c Sb an alloy is obtained which expands on cooling An amalgam of Pb (4 pts) Bi (2 pts), and Hg (1 pt) may be melted by rubbing pieces of it together Alloys of Pb with Bi and Sn are known as fusible alloy, the MP varies from c 90° to c 170°, all these alloys are said to solidify at 98° (For MP and solidification points of these alloys *v* Dallo, *C C* 1865 831, for expansion and SH *v* Spring, *A Ch* [5] 7, 178, also Wiedemann, *W* 3, 237, for thermal conductivity *v* Wiedemann a Fierz, *P* 89, 514, 108, 399, *cf* also vol 1 p 511)

Britannia metal is composed of equal parts of brass, Sn, Sb, and Bi, Queen's metal of 1 pt Pb, 1 pt Bi, 1 pt Sb, and 9 pts Sn Alloys of Pb with Bi, Sn, and Ag are very fusible, melting as low as 45°, the alloy often used for tinning the inside of glass globes, tubes, &c is made by fusing together 1 pt Pb, 1 pt Sn, 2 pts Bi, and adding 10 pts Ag

Alloys with copper *v* vol u p 254

Alloys with mercury Pb easily amalgamates with Hg, by rubbing together Pb filings with Hg or by adding Hg to molten Pb An amalgam containing 33 p c Pb is liquid, an amalgam of equal parts Pb and Hg can be crystallised Contraction occurs during the amalgamation

Alloys with potassium and sodium Prepared either by directly heating the metals together or by fusing PbO with an alkaline flux, *e.g.* with cream of tartar. When distilled with EtI, MeI, &c., compounds of Pb with Et, Me, &c. are obtained.

Alloys with tin These metals may be alloyed in all proportions, the S.G. of the alloy is always a little less than that calculated from the S.G. of the constituents. There are no indications of the formation of definite compounds (*v.* Laurie, *C J* 55, 677). These alloys are very easily ignited and burnt. The two commonest alloys of Pb and Sn are *solder* and *pewter*. *Fine solder* contains 1 pt Pb and 2 pts Sn, *common solder*, equal pts Pb and Sn, *coarse solder*, 2 pts Pb and 1 pt Sn. The M.P. varies from c 340° for 1 pt Pb and 2 pts Sn, to 370° for equ 1 parts Pb and Sn, and 440° for 2 pts Pb and 1 pt Sn, by increasing the relative quantity of Pb the M.P. rises until the alloy of 25 pts Pb to 1 pt Sn melts at c 560°, by increasing the relative quantity of Sn, above 2 pts to 1 of Pb, the M.P. also slightly rises until the alloy of 6 pts Sn to 1 pt Pb melts at c 380°. *Pewter* is an alloy of c 80 pts Pb with 20 pts Sn. According to Rudberg (*P* 18, 240) when Pb and Sn are melted together and allowed to cool, the thermometer always shows a stationary point at 187°, he thinks that a compound PbSn₂ is always formed, that this alloy has a fixed solidification point lower than that of Pb (326°) or Sn (228°), and that the heat produced by the solidification of this alloy acting on the excess of Pb or Sn causes fluctuations in the final solidification point of the whole mixture (*v.* also Pohl, *W A B* 1850 402, Riche, *C R* 55, 143, Wertheim, *P Ergänzzbd*, 2, 75, Matthiessen, *P* 130, 62). It seems that the amount of Pb in *pewter* vessels for domestic use should not exceed 18 p.c., else Pb may be dissolved out by the action of dilute acids, *e.g.* vinegar.

Alloys with tin and copper *Bell metal* is an alloy of 43 p.c. Pb, 80 p.c. Cu, 101 p.c. Sn, and 56 p.c. Zn. A little Pb is sometimes added to Cu and Sn in making *bronze*.

Alloys with palladium A crystalline, greyish white, brittle alloy is obtained by fusing granulated Pb with rather more than its own weight of Pd foil, and removing excess of Pb by the action of acetic acid and CO₂. The alloy has the composition Pd₂Pb, S.G. 11.225 (Bauer, *B* 3, 691, 4, 419).

Alloys with platinum An alloy having the composition PtPb is formed by fusing 3 pts Pb with 1 pt Pt, and exposing the product to the prolonged action of CO₂, O, and acetic acid vapour (Bauer, *B* 3, 691, 4, 449). Steel-grey, crystalline, fairly fusible, S.G. 15.736. Bauer (*l.c.*) also describes an alloy PtPb₂.

Alloys with zinc Pb and Zn alloy in all proportions, all the Zn is removed by heating very strongly. Alloying Pb with Zn increases the hardness of the Pb. Alloys of Pb, Zn, and Sn solidify at 168°, when the ratio is 2Pb Zn 9Sn the alloy solidifies at 168° only, but other alloys show also two higher points.

Lead also alloys with *chromium* and *manganese*.

Lead, antimonate of, *v.* vol 1 p 286

Lead, antimonides of Pb and Sb may be melted together in all proportions, the alloys are crystalline, most of them are formed with expansion. Ordinary *type metal* consists of 83 pts Pb and 17 pts Sb (*v.* Riche, *C R* 55, 143, Matthiessen, *P* 110, 28, Calvert a Johnson, *P M* [4] 18, 354, H v d Planitz, *B* 7, 1664, Rollmann, *P* 84, 277).

Lead, arsenates of, *v.* vol 1 p 308

Lead, arsenides of Pb melted with As takes up c 16 p.c. of the latter, the alloys are brittle and very fusible, some, but not all, of the As is expelled by heating. *Shot metal* is an alloy of Pb with not more than 3 p.c. As.

Lead, arsenites of, *v.* vol 1 p 306

Lead, borates of, *v.* vol 1 p 530

Lead, borofluoride of Pb(BF₄)₂ [= PbF₂, 2BF₃] Prismatic crystals, obtained by dissolving PbO in excess of HBF₄ and evaporating to a syrup. Crystallises with difficulty, partially decomposed by water or alcohol (Berzelius, *P* 2, 113, cf. Borofluorides, vol 1 p 526).

Lead, bromide of PbBr₂. Mol w not certain, but from analogy of PbCl₂ is probably 365.9 (= PbBr). Melts at c 499° (Carnelley, *C J* 33, 278), boils at c 861° (Carnelley a Williams, *C J* 33, 283). S.G. ppd PbBr₂ 6.572 at 19.2° (Clarke's *Table of Specific Gravities* [1888] 32). H.F. [Pb₂Br]₂ = 61,450, [PbBr₂Aq] = 54,410 (*Th*. 3, 337). Obtained by digesting PbO or PbCO₃ with HBrAq, or by ppg the solution of a Pb salt by HBrAq or a soluble bromide. Obtained in well formed, colourless, rhombic needles by slowly evaporating a solution of Pb in alcohol containing Br (Hjortdahl, *Z K* 3, 302). Sol. cold, more sol. hot, water, more sol. acids. From the solution in hot conc. HBrAq (72 p.c. HBr), Ditté says that white lustrous needles, PbBr₂·3H₂O, crystallise (*C R* 92, 718), and that the compound 5PbBr₂·2HBr·10H₂O is obtained by passing HBr into the solution of PbBr₂ in HBrAq. After melting, PbBr₂ solidifies to a yellow, horn like mass. Heated in air, a yellow mass remains containing the *oxybromide* PbOBr₂ (= PbBr₂·PbO), the same oxybromide is obtained by digesting PbBr₂ with Pb(C₂H₃O₂)₂Aq. A compound of PbBr₂ with PbCl₂ has been obtained, also compounds of PbBr₂ with PbI₂, and with Pb(CNS)₂. (*v.* **Lead, bromochloride of**, **Lead, iodobromides of**, and **Lead, bromosulphocyanides of**). André (*A Ch* [6] 3, 104) describes several *double compounds* of PbBr₂ with NH₄Br.

Lead, brom iodides of, *v.* **Lead, iodobromides of**.

Lead, bromochloride of PbBr₂PbCl₂ (= PbBrCl). White needles, observed by Illes in a blast furnace where lead carbonate ores had been reduced (*C N* 43, 216), crystallisable from water, S.G. 5.741.

Lead, bromosulphocyanides of PbBr₂Pb(CNS)₂, brownish crystals, by digesting the constituents together, and then crystallising from boiling water. By acidifying with HBrAq, the salt 8PbBr₂Pb(CNS)₂ is produced (Grisson a Thorp, *Am* 10, 229).

Lead, chlorides of Only one chloride of lead, PbCl₂, has been isolated, but there is strong proof of the existence of the tetrachloride, PbCl₄, in solutions of PbO, in HClAq.

Lead chloride, PbCl₂. (**Lead dichloride**

Plumbous chloride *Horn-lead*) Mol w 277.14 S G 5.805 at 15° (Stolba, *J pr* 97, 503), 5.88 (Brigellmann, *B* 17, 2359) V D 187.1 at c 1080° (mean of 4) (Roscoe, *Pr* 27, 426) Melts at 498°, and boils between 861° and 954° (Carnelley, *C J* 33, 278, and C A Williams, *C J* 35, 564) Crystallises in rhombic system, $a b c = 5943.1 \ 5949$ (Schabus, *W A B* 1850 456) H F [Pb, Cl] = 82,770, [Pb, Cl², Aq] = 75,970 (*Th* 3, 337)

Occurrence—As *cotumite*, found in the crater of Vesuvius after the eruption of 1822, mixed with NaCl and CuSO₄.

Formation—1 By heating Pb in a stream of Cl, combination occurs slowly—2 By dissolving Pb in hot HClAq in contact with air, PbCl₂ separates on cooling—3 By adding solution of a chloride, e.g. NaClAq, to a conc solution of a Pb salt—4 By dissolving PbS in hot HClAq and crystallising

Preparation—PbO or PbCO₃ is boiled with dilute HClAq, and HClAq is added little by little until all is dissolved, the liquid is allowed to cool, and the PbCl₂ which separates is repeatedly crystallised from boiling water

Properties—Large, white, rhombic crystals (*v supra*), which melt at 498° and boil between 861° and 954° (*v supra*) V D at c 1080° agrees with the formula PbCl₂. Sol. sol cold water, S = 95 at 16.5°, solution contains 9414 p.c. PbCl₂ (Bell, *C N* 16, 69), addition of 1 p.c. HCl diminishes S to 347, and with 14 p.c. HCl, S = 09. If more than 14 p.c. HCl is present S increases, S in HClAq S G 1.162 = 2.9 (Bell, *l c*) According to Field (*C J* [2] 11, 575) PbCl₂ is less soluble in NaClAq containing 5 p.c. NaCl than in water (S = 23), but the values of S for water and conc. NaClAq are about the same. The considerably greater solubility of PbCl₂ in conc. than in dilute HClAq is supposed by Ditte to be due to the formation of a compound of PbCl₂ and HCl which is decomposed by water (*C R* 92, 718) Ditte gives the following table—

HCl in 100 pts H ₂ O	PbCl ₂ dissolved in 1000 pts of the liquid in vol 1				
	at 0°	20°	40°	55°	80°
0	8	11.8	17	21	31
5.6	2.8	3	4.6	6.5	12.4
10	1.2	1.4	3.2	5.5	12
18	2.4	4.8	7.2	9.8	19.8
21.9	4.7	6.2	10.4	12.9	23.8
31.5	11.9	14.1	19	24	38
46	29.8	30 (at 17°)	—	—	—

PbCl₂ is readily dissolved by boiling water, but almost all crystallises out on cooling. Insol. alcohol 94 p.c., somewhat sol. in more dilute. Fairly sol. NaC₂H₃O₂Aq, Na₂S₂O₃Aq, and some other salt solutions. After melting and cooling, PbCl₂ appears as a horn-like mass (hence the name *horn-lead* formerly used)

Reactions—1 Heated in the air until white fumes cease to come off, a light yellow oxychloride Pb₂OCl₂ (= PbCl₂ PbO) is formed (*v Lead, oxychlorides of*)—2 Recently pptd PbCl₂ when digested with cold neutral lead acetate produces an oxychloride 2Pb₂OCl₂H₂O (Brandes, *A* 10, 273)—3. The oxychloride

Pb₂OCl₂H₂O is obtained by partially pptg PbCl₂Aq by lime water—4 By adding caustic potash to PbCl₂ suspended in water, the oxychloride PbCl₂ 2PbO is said to be formed (Ditte, *C R* 94, 1180)—5 According to Berzelius, the product of the action of ammonia on PbCl₂ is PbCl₂ 3PbO 4H₂O—6 Heated in carbon monoxide, COCl₂ and Pb are produced—7 Heated, not too strongly, in phosphoretted hydrogen, HCl, P, and Pb are formed—8 Oxidised by alkaline hypochlorites to PbO₂—9 Long continued passage of Cl into PbCl₂ suspended in water most probably produces PbCl₂ PbO₂ being simultaneously pptd (*v Fisher, C J* 35, 284)

Combinations—1 PbCl₂ absorbs ammonia gas, forming 2PbCl₂ 3NH₃, according to H. Rose. All the NH₃ is readily given off on warming—2 Combines with lead monoxide, when the two are heated together, to form oxychlorides xPbCl₂ yPbO (*v Lead, oxychlorides of*)—4 With lead carbonate forms PbCl₂ PbCO₃, obtained by boiling together the two salts, or by the action of CO₂ on PbCl₂ under pressure (Miller, *C J* [2] 8, 37)—5 With lead acetate to form PbCl₂ Pb(C₂H₃O₂)₂, obtained by mixing freshly pptd PbCl₂ with Pb(C₂H₃O₂)₂ and enough glacial acetic acid to form a viscid mass, which soon solidifies, and removing excess of acid by pressure (Carius, *A* 127, 87)—6 With lead phosphate, forms PbCl₂ Pb₃(PO₄)₂ H₂O and PbCl₂ 2Pb₃(PO₄)₂, or according to Gerhardt (*A Ch* [3] 22, 505) PbCl₂ Pb₂H(PO₄)₂. The former is produced by pouring boiling PbCl₂Aq into excess of boiling Na₂HPO₄Aq, the latter by pouring the Na phosphate into the PbCl₂ solution (Heintz, *P* 73, 122) *Pyromorphite* PbCl₂ 3Pb₃(PO₄)₂ occurs native—7 Combines with lead bromide to form PbCl₂ PbBr₂, with lead iodide to form PbCl₂ PbI₂, with lead fluoride to form PbCl₂ PbF₂, and with lead sulphocyanide to form PbCl₂ Pb(CNS)₂ (*v Lead bromochloride, Lead iodobromides, Lead chlorofluoride, and Lead chlorosulphocyanide*)—8 Probably combines with chlorine to form PbCl₄, when Cl is passed into PbCl₂ dissolved in considerable excess of HClAq, or when Cl is passed into PbCl₂Aq mixed with CaCl₂ (*v Lead tetrachloride*)—9 André (*A Ch* [6] 3, 104) describes various double compounds of PbCl₂ with NH₄Cl

LEAD TETRACHLORIDE (*Plumbic chloride*) No other chloride of lead except PbCl₂ has been isolated, but there is considerable evidence in favour of the existence in HCl solution of tetrachloride PbCl₄.

If a considerable quantity of HClAq is added to PbCl₂, and Cl is passed in, the PbCl₂ dissolves to a reddish brown liquid, on warming Cl is evolved, addition of water causes pptn of PbO₂.

A mixture of PbCl₂Aq with CaCl₂Aq absorbs much Cl and forms a deep yellow liquid, which may be preserved unchanged in a closed vessel, but is decomposed in an open vessel giving PbCl₂ and Cl, a few drops of this liquid added to a large quantity of water gives a ppt of PbCl₂ and PbO₂, alkalis and alkaline carbonates ppt PbO₂, MnCl₂Aq ppts MnO₂ and PbCl₂, Fe, Cu, Zn, gold leaf, and finely divided Pt, are soluble in the liquid with separation of PbCl₂, it rapidly oxidises many organic bodies, PbCl₂ being pptd.

(Sobrero & Salmi, *A Ch* [8] 29, 165, Nicklès, *A Ch* [4] 10, 323)

PbO₂ dissolves in cold fairly conc HClAq. From this yellow solution, alkalis, alkaline carbonates, oxides and carbonates of Ba, Mg, Zn, &c., and alkaline borates and acetates, ppt PbO₂. The solution smells of Cl and is decomposed by heat with evolution of Cl and ppt of PbCl₂. If the HClAq is saturated with PbO₂, the addition of water ppts PbO₂. Fisher (*C J* 35, 282) determined the ratio of Pb pptd from this solution by water as PbO₂ to Cl given off by decomposing the solution with ppt of PbCl₂. The ratio was almost exactly Pb 2Cl, now this is the ratio required on the hypothesis that the decomposition by water proceeds as shown in equation (1), and the decomposition to PbCl₂ and Cl proceeds as shown in equation (2)—

Fisher proved that the whole of the Pb in solution is thrown down by water as PbO₂. A yellow liquid with properties the same as those of the ratio just described is obtained by treating Pb₂O₃ with a considerable quantity of HClAq (Fisher, *l c*)

By the method described above, Sobrero & Salmi (*l c*) obtained a double salt PbCl₂.9NaCl, and Nicklès (*l c*) obtained PbCl₂.16CaCl₂. Evaporation *in vacuo*, over conc KOHAq, of a solution of PbO₂ in HClAq produces crystals of PbCl₂, containing some PbCl₄, according to Bendant & Daguin (*Ann M* [5] 4, 239, *v* also Nikolukine, *J R* 1885 207, abstract in *C J* 50, 123)

Lead, chlorobromide of, *v* Lead, bromo-*hydrides of*

Lead, chlorocarbonate of, *v* Lead chloride, *Combinations No 4*

Lead, chlorocyanide of, *v* Lead cyano-*chloride of*

Lead, chlorofluoride of PbCl₂PbF₂ (=PbFCl). Obtained by ppg boiling PbCl₂Aq by KFAq, or Pb(C₂H₃O₂)₂Aq by a solution of 2 parts NaF with 3 parts NaCl (Berzelius). A white powder, slightly soluble in water without decomposition

Lead, chloronitrides of, *v* Lead, iodo-*chlorides of*

Lead, chlorophosphate of, *v* Lead chloride, *Combinations No 6*

Lead, chlorosulphide of, *v* Lead, sulpho-*chloride of*

Lead, c'lorosulphocyanide of, PbCl₂Pb(CNS)₂, by digesting the constituents together, and crystallising from boiling water, slowly changed to PbO₂H₂ by NH₃Aq (Grisson & Thorp, *Am* 10, 229)

Lead, chromates of, *v* vol II pp 155 and 157

Lead, cyanides of. None has been isolated, but an *oxycyanide*, and also *ferri-* and *ferro-* cyanides, are known, *v* vol II pp 341, 339, and 335

Lead, cyanochloride of PbCl₂.2PbCy₂, by digesting PbCl₂ with KCyAq (Grisson & Thorp, *Am* 10, 229)

Lead, ferricyanide of, *v* vol II p 349

Lead, ferrocyanide of, *v* vol II p 335

Lead, fluochloride of, *v* Lead, chloro-*fluoride of*

Lead, fluoride of PbF₂. Pb is not acted on by HFAq, PbO₂H₂, or PbCO₃, dissolves in HFAq, and on evaporating, and heating to remove HF, PbF₂ remains. PbF₂ is also pptd on adding Pb(C₂H₃O₂)₂Aq to HFAq. A white powder, slightly soluble in water, sol in HNO₃Aq (Berzelius). Gunz (*A Ch* [6] 3, 5) gives H F of PbF₂ as (PbO·H₂·2HF) = 24,300

Lead, hydroxides of, *v* Lead, oxides and *hydrated oxides of*

Lead, iodide of PbI₂. Mol w not certainly known, but from analogy of PbCl₂, probably 459.46 (=PbI₂). S.G. 6.12, 5.6247 molten at 383° (Rodwell, *T* 1882 1144). Melts at 383°, and boils between 861° and 954° (Carnelley, *C J* 33, 277, C a Williams, *C J* 37, 126). For expansion of PbI₂, *v* Rodwell, *Pr* 32, 23. H F [Pb, I] = 39,800 (*Th* 3, 337)

Preparation—Solution of Pb(NO₃)₂ is added to solution of FeI₂, the pp is washed with cold water and dried. KI or CaI₂ may be used instead of FeI₂. If Pb(C₂H₃O₂)₂Aq is added to KIAq oxyiodides are formed when excess of Pb salt is added, and soluble double iodides are formed if excess of KI is present, to prevent both results the solution of Pb(C₂H₃O₂)₂ should be acidified either with HNO₃ or C₂H₃O₂.

Properties and Reactions—Golden yellow crystals, hexagonal, *a c* = 1.3018 (Norden-skjöld). Melts when heated to a brown red liquid, and solidifies to a yellow mass. Heated in the air I is evolved, and oxyiodides (*q v*) are formed. S cold water 03, boiling water 515. Decomposed by Cl. Zn or Fe boiled with PbI₂ under water forms ZnI₂ or FeI₂, and ppts Pb. Na₂S₂O₃ in excess forms Pb sulphite and NaI (Michaelis & Koethe, *B* 6, 999). NH₃Aq added to boiling PbI₂Aq ppts 3PbO.PbI₂.2H₂O. Dry PbI₂ is unchanged by light, when moist and exposed to direct sunshine, in contact with the air, it is slowly changed to PbCO₃ and PbO, with separation of I, this change is hastened by all substances which absorb I (Schmid, *P* 127, 493). PbI₂ is somewhat soluble in conc solution of alkali iodides, but is pptd on dilution.

Combinations—1 Absorbs ammonia, forming a white compound PbI₂.2NH₃.—2 With lead monoxide forms various oxyiodides xPbI₂.yPbO (*v* Lead, oxyiodides of).—3 By dissolving PbI₂ in warm iodohydric acid solution, and allowing to cool, white lustrous needles of PbI₂.2HI = H₂PbI₄ separate. This compound may be called *iodo plumbhydric acid* or *iodo plumbic acid*, it is decomposed by water, gives off HI *in vacuo*, according to Berthelot, the crystals contain 10H₂O (*C R* 91, 1024).—4 PbI₂ combines with potassium iodide to form various double salts, one of which, PbI₂.2KI, seems best regarded as the K salt of H₂PbI₄. Yellow, lustrous leaflets of PbI₂.KI are obtained by dissolving the constituent salts in the ratio PbI₂.KI in boiling water, and allowing to cool, by dissolving this salt in warm KIAq and cooling, the salt PbI₂.4KI is said to be obtained in white needles (Boullay, *A Ch* [2] 34, 366). Remsen (*Am* 11, No 5) asserts that the process described by Boullay does not result in production of PbI₂.4KI, and that the salt formed with most ease when PbI₂ and KI react under different conditions is PbI₂.KI.H₂O (*cf* Ditte, *C R* 92, 1841).—5 By mixing a boiling solution of KI

and NH_4Cl with $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$, taking care that no permanent pp was formed, and cooling, Völkel obtained clear yellow lustrous needles of $\text{PbI}_2 \cdot 2\text{NH}_4\text{Cl}$ (P 62, 252), decomposed by water with separation of PbI_2 . By saturating hot NH_4ClAq with PbI_2 , cooling, pouring off from $\text{PbI}_2 \cdot 2\text{PbCl}_2$, which separates, and evaporating, Poggiale (C R 20, 1180) obtained $\text{PbI}_2 \cdot 4\text{NH}_4\text{Cl} \cdot 2\text{H}_2\text{O}$, decomposed by water with separation of PbI_2 . — 6 PbI_2 combines with *silver iodide*. For properties of the PbI_2AgI produced v Rodwell (Pr 32, 540), Bellati a Romanese (Pr 34, 104). — 7 Compounds with *lead bromide* are formed by crystallising PbI_2 from HBrAq (v *Lead, iodobromides of*) — 8 Compounds with *lead chloride*, $\text{PbI}_2 \cdot \text{PbCl}_2 (= \text{PbClI})$ and $\text{PbI}_2 \cdot 2\text{PbCl}_2$, are known (v *Lead, iodochlorides of*) — 9 By boiling PbCO_3 repeatedly with PbI_2Aq , Poggiale (C R 20, 1184) obtained $\text{PbI}_2\text{PbCO}_3$. — 10 $\text{PbI}_2 \cdot \text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ was obtained by Carus (A 127, 87) similarly to the PbCl_2 compound (v *Lead chloride, Combinations No 5*)

Lead, iodobromides of By crystallising PbI_2Aq from HBrAq , Grisson a Thorp obtained the compounds (1) $\text{PbBr} \cdot \text{PbI}_2$, (2) $3\text{PbBr} \cdot \text{PbI}_2$, (3) $6\text{PbBr} \cdot \text{PbI}_2$ (Am 10, 229)

Lead, iodicarbonate of, v *Lead, iodide of, Combinations No 9*

Lead, iodochlorides of The compound $\text{PbClI} (= \text{PbCl}_2 \cdot \text{PbI}_2)$ is obtained, in sulphur yellow prisms, by cooling a solution of PbI_2 in boiling HClAq (Laboure, J Ph [3] 4, 328) According to Engelhardt the compound contains more PbI_2 than required by the above formula (J pr 67, 293) By saturating hot NH_4ClAq with PbI_2 , and allowing to cool, Poggiale obtained yellow needles of $\text{PbI}_2 \cdot 2\text{PbCl}_2$ (C R 20, 1180)

Lead, iodosulphocyanide of, $\text{PbI}_2 \cdot 3\text{Pb}(\text{CNS})_2$, formed with some difficulty by digesting the constituents and crystallising from hot water (Grisson a Thorp, Am 10, 229)

Lead, oxides and hydroxides (or hydrated oxides) of Five oxides of lead have been isolated, viz, Pb_2O , PbO , Pb_2O_3 , Pb_3O_4 , and PbO_2 , one or more oxides intermediate between Pb_2O_3 and PbO_2 perhaps exist Two hydrates of PbO , viz $2\text{PbO} \cdot \text{H}_2\text{O}$ and $3\text{PbO} \cdot \text{H}_2\text{O}$ are known, the hydrates $\text{Pb}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ and $\text{PbO}_2 \cdot \text{H}_2\text{O}$ have also been isolated The most stable oxide is PbO , Pb_2O is easily oxidised to PbO by heating in air, and Pb_2O_3 , Pb_3O_4 , and PbO_2 are reduced to PbO when strongly heated PbO reacts with acids as a basic oxide, forming salts PbX_2 , $\text{X} = \text{NO}_3$, Cl , $\frac{1}{2}\text{SO}_4$, $\frac{1}{2}\text{PO}_4$, &c., it decomposes NH_3 salts, evolving NH_3 , and combines with CO_2 to form PbCO_3 , PbO also reacts with strongly basic oxides as an acidic oxide forming unstable *plumbites*, e g K_2PbO_2 , PbO reacts as an acidic peroxide, with KOH and NaOH it forms fairly stable *plumbates*, M^+PbO_3 , with most acids it forms salts of PbO , but it appears capable of dissolving without reduction in glacial acetic and phosphoric acids The reactions of Pb_2O_3 and Pb_3O_4 indicate that these oxides are compounds of the form $x\text{PbO} \cdot y\text{PbO}_2$ As none of the oxides of Pb has been gasified the molecular weight of none is known with certainty

LEAD SUBOXIDE, Pb_2O The grey pellicle which forms on the surface of lead exposed to the air consists of Pb_2O , according to Berzelius

Pb_2O is prepared by heating PbC_2O_4 in a retort to near 800° as long as any gas is given off, $2\text{PbC}_2\text{O}_4 = \text{Pb}_2\text{O} + \text{CO} + 3\text{CO}_2$, the residue is allowed to cool in the retort (Dulong, S 17, 229, Pelouze, J pr 25, 486) Pb_2O is a black powder, SG 9 772 (Playfair a Joule, C S Mem 3, 83), heated in air it burns to PbO , heated out of contact with air, PbO and Pb are produced Moist Pb_2O rapidly absorbs O from the air, forming white $\text{PbO} \cdot x\text{H}_2\text{O}$ Dilute acids resolve Pb_2O into PbO , which dissolves, and Pb , saturated $\text{Pb}_2\text{NO}_3\text{Aq}$ produces a similar resolution, but Pb_2O is wholly soluble in dilute $\text{Pb}_2\text{NO}_3\text{Aq}$ This oxide was at one time supposed to be a mixture of PbO and Pb , but this is disproved by the facts that when the oxide is rubbed with Hg either dry or under water, no Pb is removed, and that PbO is not removed from it by boiling with Pb acetate solution

LEAD PROTOXIDE PbO (*Plumbous oxide* *Litharge* *Massicot*) Mol w unknown, as oxide has not been gasified SG 9 277 at 17.8° (Herapath, P M 64, 321), 9 25 (Playfair a Joule, C S Mem 3, 84), 9 17 to 9 88 (Ditte, C R 94, 1310), 8 74 to 9 29 (Geuther, A 219, 60) H F $[\text{PbO}] = 50,300$, heats of neutralisation $[\text{PbO} \cdot 2\text{HClAq}] = 56,830$, $[\text{PbO} \cdot \text{HNO}_3\text{Aq}] = 24,250$ to form basic nitrate (Th 3, 337) Crystallises in rhombic forms $a \cdot b \cdot c = 666 \cdot 1 \cdot 971$ (Nordenskjöld, P 114, 619, v also Mitscherlich, P 49, 403, J pr 19, 451, Grailich, W A B 28, 282, Marx, J pr 3, 217) PbO is dimorphous according to Ditte (C R 94, 1310)

Occurrence — As *lead ochre*, in small quantities in Mexico, Baden, Virginia, and a few other localities

Formation — 1 By heating Pb to low redness in presence of air, if the temperature is kept below the melting point of the PbO , the oxide is obtained as a yellowish powder, known commercially as *massicot*, if the PbO is melted during the preparation, the oxide solidifies to a scaly reddish solid known as *litharge* — 2 By heating Pb with KNO_3 — 3 By strongly heating red lead in air — 4 By strongly heating 'white lead' on an iron plate — 5 By adding boiling Pb acetate solution to boiling KOH Aq , pp is crystalline (Winkelblech, A 21, 21, J pr 10, 227) — 6 By slowly pouring Pb acetate solution into CaOAq at 80° until a crystalline crust appears, then adding a little more, and allowing to cool (Brendecke, R P 55, 118) — 7 By adding PbSO_4 made into a paste with water, to boiling NaOHAq (Wichmann, C C 1860 334) For modifications of these processes v Payen, J pr 13, 485, Behrens, B J 24, 134 8 According to Yorke (P M [3] 5, 82), crystals of PbO are produced by placing Pb in a vessel of water exposed to the air The reaction of steam with Pb at white heat produces PbO

Preparation — 1 Basic Pb nitrate is heated in a Pt crucible until completely decomposed (the neutral salt melts before decomposition is complete) Berzelius recommends the following procedure Equal weights of PbO and Pb_2NO_3 are kept in boiling water until the PbO is wholly transformed into basic nitrate, the basic salt is dissolved in boiling water, the solution is filtered hot and allowed to cool, the basic nitrate which separates is subjected to the action of the boiling solution as long as any solid separates on cooling.

A small quantity of the basic nitrate is made into a paste with water, the inside of a Pt crucible is covered with this paste, and the crucible is dried, the rest of the salt is strongly pressed while moist, then dried, and broken into smaller pieces, which are placed in the crucible, which is then heated until the decomposition is completed. The PbO formed from the pieces of basic nitrate in the middle of the crucible is pure, the outer layers of PbO contain a little Pt—2 PbO is prepared in crystalline form by dissolving PbO, prepared as in 1, in hot KOHAq or NaOHAq, and allowing to cool. The colour and SG of the crystals vary with the conditions. Ditte (C R 94, 1310) obtained a greenish crystalline mass (SG 9 1699) by heating KOHAq c 13 p.c. with PbO \cdot 2H₂O, using 25 p.c. KOHAq he obtained sulphur yellow lustrous crystals (SG 9 2089), brownish needles (SG 9 8835) were obtained by using 30 p.c. KOHAq and allowing to cool, KOHAq 185 p.c., saturated with PbO \cdot 2H₂O when hot, gave deep green, almost black, crystals on cooling (SG 9 5605), saturated KOHAq boiled with PbO \cdot 2H₂O gave deep rose coloured crystals of PbO (SG 9 4223), differing in form from the usual crystals, and becoming yellow when strongly heated (cf. Mitscherlich, J pr 19, 451, Calvert, B J 24, 135, Becquerel, A Ch [2] 51, 105).

Properties—PbO is a yellow to reddish yellow crystalline solid, the colour and SG of the oxide when well crystallised seem to vary with the conditions of formation, *v Preparation*, No 2. Melts between 585° and 630° to a clear dark red liquid. According to Leblanc (B J 26, 193) molten PbO absorbs O, which it gives off on solidifying. PbO is sl sol water, 1 part dissolves in c 7000 water, the solubility is affected by the state of aggregation of the PbO (cf. Bineau, C R 1855 877), if the solution is exposed to the air CO₂ is absorbed, and the PbO as basic carbonate, the PbO is also removed by filtration through paper (Yorke, P M [3] 5, 82). Heated to between 300° and 450° in air, PbO is oxidised to Pb₂O₃, but at higher temperatures Pb₂O₃ is deoxidised to PbO. PbO is soluble in warm conc KOHAq or NaOHAq. Geuther (A 219, 56) says that two varieties of PbO exist, one yellow and the other red, the yellow crystallises in rhombic, the red in hexagonal, forms.

Reactions—1 Heated in air Pb₂O₃ is formed at c 300°–450°, at a somewhat higher temperature PbO is re formed—2 Heated in hydrogen, or carbon monoxide, reduction to Pb occurs at a little above 100°, PbO is also reduced to Pb by heating with C, Na, or KCN—3 Reacts with most acids to form salts PbX₂, X = NO₃, Cl, SO₄, &c., absorbs CO, from the air forming PbCO₃—4 Decomposes alkali salts with separation of the alkali—5 Dissolves in warm fairly conc potash or soda solution, probably with formation of plumbites K₂(Na₂)PbO₂—6 Dissolves in molten potash forming K₂PbO₂, which, on long continued heating in air, is oxidised to K₂PbO₄ (Carnegie, C N 60, 113) (*v PLUMBATES* under LEAD PEROXIDE, p 132)—7 Dissolves also by boiling with milk of lime on evaporating in absence of air a compound separates in needles, probably CaPbO₂—8 Molten PbO dissolves silica, easily forming glass like silicates, these

silicates readily dissolve CaO, Al₂O₃, &c.—9 Heated in chlorine, bromine, or iodine vapour, the compound PbCl₂, PbBr₂, or PbI₂ is formed, heated with Cl and air, Br and air, or I and air, the product is Pb₂Cl₂, Pb₂Br₂, or Pb₂I₂ (Cross a Sigura, C J 33, 405)—10 By boiling excess of PbO with conc calcium chloride solution, filtering, and washing with alcohol the pp that forms on cooling, André (C R 104, 359) obtained 2PbO CaO CaCl₂ 4H₂O, by using strontium chloride he obtained 2PbO SrCl₂ 5H₂O—11 PbO does not react with phosphorus trichloride at 160°, but when heated together over a flame, PbO and PCl₃ react violently forming PbCl₂, Pb(H₂PO₃)₂, and P (Michaels, J pr [2] 4, 449)—12 Dissolves in magnesium chloride solution, on filtering and evaporating, the oxychloride 8PbO PbCl₂ H₂O separates (Voigt, Chem Zeitung, 13, 695).

HYDRATES OF LEAD MONOXIDE—1 3PbO H₂O, obtained by adding c 400 grams KOH to 1000 cc water containing freshly pptd PbO in suspension (Ditte, C R 94, 1310), also by adding basic Pb acetate solution to NH₄Aq at 20°–25°, and digesting the pp under the liquid for some time (Payen, A Ch [4] 8, 302, Behrens, B J 24, 134). This hydrate forms lustrous octahedral crystals, SG 7 592 at 0° (Ditte, C R 94, 1310), loses some H₂O at 130°, and is entirely dehydrated at 145°, a sol caustic alkali solutions—2 2PbO H₂O By pptg Pb(C₂H₃O₂)₂ Aq by KOHAq or NaOHAq, and digesting with excess of pptant, if Pb(NO₃)₂ is used some basic nitrate is always formed (Schaffner, A 51, 175). The hydrates of PbO readily absorb CO₂ from the air, they also combine with NH₃ to form PbO H₂O 2NH₃ and 8PbO 2NH₃ H₂O (Calvert, C R 23, 480).

Plumbites Although PbO is a markedly basic oxide, it nevertheless dissolves in alkali solutions to form unstable salts of the form M₂PbO₂, these salts, plumbites, have not been much investigated, according to Carnegie (C N 60, 113) K plumbite is formed by dissolving PbO in molten KOH, and on long continued heating in air it is oxidised to plumbate K₂PbO₄. The Ag salt is produced by adding NaOHAq to a mixture of a Pb and a Ag salt, Wöhler gives the formula Ag₂O 2PbO Krutwig (B 15, 1264) obtained a yellow salt, Ag₂PbO₂ 2H₂O, by adding AgNO₃Aq to alkaline Pb(NO₃)₂Aq, and washing with hot KOHAq and then with hot water, the salt soon became black in the air.

LEAD SESQUIOXIDE Pb₂O₃ (*Plumbo plumbica oxide*) Mol w unknown, as oxide has not been gashed. A reddish yellow powder resembling PbO, Debray describes Pb₂O₃ as greenish-brown (C R 86, 513). Debray (l.c) prepares this oxide by heating PbO₂ to 350°, or by heating PbO or better PbCO₃ to the same temperature in a stream of air or O, Carnellea Walker (C J 53, 85) say that PbO₂ is changed to Pb₂O₃ at 280°–290°, and that Pb₂O₃ gives off O at c 370°. According to Jacquelin (J pr 53, 153) Pb₂O₃ may be obtained by pouring a solution of red lead, Pb₃O₄, in glacial acetic acid into very dilute NH₄Aq, separating the pp quickly, washing it with hot water containing a very little acetic acid, and drying at 100°. Winkelblech (A 21, 21) obtained this oxide by pouring NaOHAq into Pb(C₂H₃O₂)₂Aq until the pp dissolved, and then

adding cold NaClO_4aq , taking care to avoid excess which would produce PbO_2 . Debray asserts that this method yields only a mixture of PbO and PbO_2 . Pb_2O_3 is not decomposed by heat until c 860° , but a little above this temperature it gives off O, leaving Pb_2O_3 , heated to c 530° , PbO is produced (Carnelley & Walker, *C J* 53, 85). Pb_2O_3 is resolved by acids into PbO_2 and a salt of PbO . Winkelblech's statement that Pb_2O_3 is dissolved unchanged by HClAq , from which solution it may be pptd again by alkalis, is denied by Hausmann (*A* 91, 235). Pb_2O_3 is reduced to PbO by $\text{H}_2\text{C}_2\text{O}_4\text{aq}$ or $\text{H CO}_3\text{HAq}$.

HYDRATE OF LEAD SESQUIOXIDE $\text{Pb}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$
Obtained by adding PbO to conc $\text{K}_2\text{PbO}_4\text{Aq}$, as a red curdy ppt (Seidel, *J pr* [2] 20, 200). The solution of K_2PbO_4 is obtained by dissolving pure PbO_2 in molten KOH with a very little water, and then dissolving the fused mass in a small quantity of water.

RED OXIDE OF LEAD Pb_2O_3 , (*Diphumboplumbic oxide* Red lead *Minium*) Mol w unknown, as oxide has not been gasified SG 9.096 at 15° (Herapath, *P M* 64, 321).

Occurrence—*Minium* is found mixed with other lead ores in Yorkshire, Anglesey, Virginia, the Eifel, &c.

Formation—By heating PbO in air to low redness (not above 450°) for some time, and cooling slowly—2 By adding PbO in KOH Aq to $\text{K}_2\text{PbO}_4\text{Aq}$, washing the ppt with hot water, and heating it—3 Finely divided ppt Pb exposed to air in presence of water and a little NH_4Aq is slowly changed to Pb_2O_3 , mixed with Pb carbonate (Schonbein, *J pr* 74, 323).

Preparation—1 A mixture of 1 pt KClO_3 , 4 pts PbO (prepared by heating PbCO_3), and 8 pts KNO_3 is heated, the mass melts, and PbO_2 is formed and on continued heating is changed to Pb_2O_3 , the fused mass is treated with water and the residue is boiled with dilute KOH Aq , to dissolve unchanged PbO , washed and dried (Levol, *J pr* 22, 38)—2 5 to 6 pts $\text{Pb(NO}_3)_2$ are dissolved in water, and KOH is added until the ppt which forms is dissolved, to this liquid is added 1 pt PbO_2 , and the whole is boiled for some time, unchanged PbO_2 is decomposed by digesting with $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$, and the PbC_2O_4 formed is dissolved in KOH Aq , the residue is washed and dried (Levol, *lc*)—3 Commercial red lead usually contains some PbO , this may be removed by digestion with dilute acetic acid, or better with lead acetate solution Lowe (*D P J* 271, 472) recommends to digest 1 pt commercial red lead with 10–15 pts of a 10 p c solution of $\text{Pb(NO}_3)_2$, for some time at a gentle heat, then to boil, and finally wash well.

Properties—A scarlet crystalline granular powder, when heated it becomes brighter red and then violet, at c 500° – 530° decomposition to PbO and O occurs SG according to different observers varies from 8.94 to 9.1 (*v* Clarke's *Specific Gravity Tables* [2nd ed], p 47). Insol water, reacts with dilute acids to form salts of PbO , and PbO_2 which remains undissolved, with conc H_2SO_4 , or HClAq , gives salts of PbO and O or Cl. Dissolves completely in glacial acetic acid forming a liquid which acts as an energetic oxidiser (*v* *Reactions*, No 6). Pb_2O_3 is readily reduced to PbO , e.g. by SO_4Aq or HNO_3Aq .

Reactions—1 Heated to c 500° – 530° , gives

PbO and O—2 Reduced to PbO by easily oxidised bodies, e.g. SO_4Aq , HNO_3Aq , solution of sugar—3 With stannous chloride gives PbCl_2 , and SnCl_4 —4 Dissolves in considerable quantity of conc cold hydrochloric acid to form a yellow liquid from which alkalis, alkaline carbonates, borates, and acetates, and oxides and carbonates of Ba, Mg, Zn, &c ppt PbO_2 , on heating, the solution decomposes to PbCl_2 and Cl, this solution almost certainly contains PbCl_4 , on warming Cl is evolved and PbCl_2 ppt (Fisher, *C J* 35, 282, *v* *Lead tetrachloride*, p 126). Dilute HClAq forms PbCl_2 , H_2O , and PbO_2 . Warm HClAq in excess evolves Cl and ppts PbCl_2 —5 Dilute sulphuric, nitric, or acetic acid, and other dilute acids ppt PbO_2 and form sulphate, &c of PbO . Hot conc H_2SO_4 forms PbSO_4 , and O—6 Pb_2O_3 dissolves in glacial acetic acid, this solution is strongly oxidising, e.g. it converts SO_4Aq to SO_4Aq , $\text{As}_2\text{O}_3\text{Aq}$ to $\text{As}_2\text{O}_5\text{Aq}$, PbS to PbSO_4 , Pb , Hg , and Cu to oxides, separates I from KI (Schönbein, *J pr* 74, 315), when dropped into dilute NH_4Aq a ppt of Pb_2O_3 is produced (Jacquelain, *J pr* 53, 153, *v* *Lead sesquioxide*, p 129). According to Jacquelain (*loc cit*) a solution of Pb_2O_3 in glacial acetic acid at 40° gives crystals of $\text{PbO}_4(\text{C}_2\text{H}_3\text{O}_4)_2$, $[\text{O}=8, \text{C}=6]$ [old notation], these crystals may be kept under acetic acid but give PbO , and $\text{H}_2\text{C}_2\text{O}_4$, on warming, or with water. Schonbein (*J pr* 74, 315) says that conc acetic acid dissolves about 9 p c of Pb_2O_3 , when shaken for 15 mins with excess of the finely powdered oxide, the solution is easily decomposed by heat or dilution, but is stable at c -18° , by careful addition of H_2SO_4 , PbSO_4 is pptd and an acetate corresponding to Pb_2O_3 remains in solution, this solution deposits PbO_2 , slowly at ordinary temperatures, quickly when heated, addition of KOH Aq does not ppt Pb_2O_3 , but a mixture of PbO and PbO_2 —7 Pb_2O_3 dissolves in conc phosphoric acid, the solution reacts similarly to that of Pb_2O_3 in acetic acid. By using a mixture of phosphoric and sulphuric acids, a solution is obtained containing only the phosphate corresponding to Pb_2O_3 , and free from PbO (Jacquelain, *J pr* 53, 152, *v* *Lead peroxide*, p 131)—8 Conc solutions of arsenic and tartaric acids dissolve Pb_2O_3 , the solutions resemble those in acetic and phosphoric acids, but are more easily decomposed.

Composition and constitution of red lead—When PbO is heated in air, O is slowly and continuously absorbed, when c 176 p c O has been absorbed the product is red, but absorption of O continues, and some specimens of red lead contain 2.67 p c O in excess of that contained in the PbO (Jacquelain, *J pr* 53, 151). An absorption by PbO of 1.79 p c O corresponds with the formation of Pb_2O_3 , the formation of Pb_2O_3 requires 2.39 p c. Older analyses of red lead led to the supposition that it was Pb_2O_3 (Dumas, *B J* 13, 113). Careful syntheses and analyses have, however, shown that a definite red coloured oxide exists having the composition Pb_2O_3 . At the same time the analyses of commercial red leads made by Mulder (*J pr* 50, 438) and Jacquelain (*J pr* 53, 151) show that the percentage of O above that required to form PbO varies from 1.16 to 2.67. Several samples of red lead agreed in composition with the formula Pb_2O_3 .

others approached Pb_2O_3 , (*cf* Löwe, *D P J* 271, 472) It is still doubtful whether a series of oxides exists of the form $x\text{PbO} \cdot y\text{PbO}_2$, x varying from 1 to 3 or 4 and y from 1 to 2 or 3, or whether only two such oxides are definite bodies, viz $\text{PbO} \cdot \text{PbO}_2 (= \text{Pb}_2\text{O}_3)$ and $2\text{PbO} \cdot \text{PbO}_2 (= \text{Pb}_3\text{O}_4)$

Red lead, Pb_3O_4 , may be regarded either as $2\text{PbO} \cdot \text{PbO}_2$ or as $\text{PbO} \cdot \text{Pb}_2\text{O}_3$, the reaction of Pb_3O_4 with acids, the synthesis of Pb_3O_4 by the action of PbO in KOH aq on $\text{K}_2\text{PbO}_2 (= \text{K}_2\text{O} \cdot \text{PbO}_2)$, and the fact that Pb_3O_4 is acidic towards some oxides, point to the constitution $2\text{PbO} \cdot \text{PbO}_2$ rather than $\text{PbO} \cdot \text{Pb}_2\text{O}_3$

LEAD PEROXIDE PbO_2 (*Brown oxide of lead* *Puce oxide of lead* *Lead dioxide*) Mol w unknown, as oxide has not been gasified SG 8 902 at 16.5° (Herapath, *P M* 64, 321), 8 756 to 8 897 (Playfair a Joule, *C S Mem* 3, 84), 9 045 (Wernicke, *P* 141, 109)

Occurrence—As *plattnerite*, at Leadhills, in hexagonal prisms

Formation—1 By boiling a Pb salt with a filtered solution of bleaching powder —2 By digesting red lead with dilute HNO_3 aq, and washing the residue —3 By mixing solutions of Pb acetate (4 pts) with soda crystals ($3\frac{1}{2}$ pts), and passing Cl into the mixture $2\frac{1}{2}$ pts PbO_2 are obtained, PbCl_2 is not formed (Wehler, *J pr* 90, 383, *cf* Geuther, *A* 96, 382)—4 By heating PbO with KClO_3 to less than red heat and washing the mass with water —5 By boiling PbO in H_2O with $\text{K}_2\text{FeC}_7\text{O}_{14}$ aq in presence of KOH ($2\text{K}_2\text{FeC}_7\text{O}_{14} + 2\text{KOH} + \text{PbO} = 2\text{K}_2\text{FeC}_7\text{O}_{14} + \text{PbO}_2 + \text{H}_2\text{O}$, Overbeck, *Ar Ph* [2] 85, 5)—6 By fusing PbO with KOH for some time (Becquerel, *A Ch* 51, 504) Carnegie (*C N* 60, 113) obtained $\text{PbO}_2 \cdot \text{H}_2\text{O}$ by long continued fusion of PbO in KOH solution in water, and careful neutralisation by dilute H_2SO_4 aq (*v Hydrates of lead peroxide, infra*) —7 By oxidising PbO by an alkaline solution of KMnO_4 (Reynoso, *C R* 32, 646)—8 By electrolysis strongly alkaline solutions of Pb salts, the hydrate $\text{PbO} \cdot \text{H}_2\text{O}$ ($q v$) is deposited on the positive electrode (Becquerel, *A Ch* [3] 8, 405) By slowly electrolysis a solution of 1 pt $\text{Pb}(\text{NO}_3)_2$ in 8 pts water, Wernicke obtained PbO_2 (*P* 141, 109)—9 PbO_2 is obtained, mixed with PbO , by shaking basic Pb acetate with H_2O_2 aq (Schonbein, *J pr* 75, 85)

Preparation—1 Very finely powdered Pb acetate is boiled with a filtered solution of bleaching powder, the liquid being poured off, and fresh solution added from time to time until no Pb is found in solution, the residue is washed with very dilute HNO_3 aq, and then with hot water, and dried at a low temperature (Böttger, *J pr* 73, 493)—2 Fehrmann (*B* 15, 1882) recommends to add a filtered solution of bleaching powder to conc PbCl_2 aq at 50° to 60° , until a few drops of the supernatant liquid cease to show a brown colour when filtered, and to wash the pp out of contact with air

Properties—A dark puce brown powder, black according to Fehrmann (*B* 15, 1882) The native compound forms metal like, lustrous, iron-black, hexagonal crystals, SG 9 392 to 9 448 (Breithaupt, *J pr* 10, 508) When heated, PbO_2 gives Pb_2O_3 and O , and at a higher temperature it is resolved into PbO and O Readily

parts with O to oxidisable bodies, *eg* rubbed with P or S vivid combustion occurs, sugar and gallic acid &c are ignited by trituration with PbO_2 . Acids generally react with PbO_2 to form salts of PbO , cold conc HCl aq seems to produce PbCl_2 , and solutions of PbO in glacial acetic and phosphoric acids probably contain salts corresponding with PbO_2 (*v Reactions*, No 9) PbO_2 reacts with strongly basic oxides as an acidic oxide to form plumbates M_2PbO_4 (*v infra*, *Plumbates*) On account of its readiness to part with O , PbO_2 is largely used for forming a surface on which to strike 'safety' matches

Reactions—1 Heated, easily goes to PbO , and O , and at a higher temperature to PbO and O —2 Readily gives up $\frac{1}{2}$ of its O to easily oxidised bodies, either at the ordinary temperature or by slightly heating, *eg* when PbO_2 is rubbed with an equal weight of $\text{H}_2\text{C}_2\text{O}_4$, H_2O , CO_2 , and PbCO_3 are formed, PbO_2 rubbed with $\frac{1}{2}$ pt sugar or $\frac{1}{2}$ pt tartaric acid oxidises these rapidly, causing ignition, P is oxidised and ignited when rubbed with PbO_2 (*v Böttger*, *A* 34, 94)—3 Sulphur dioxide is rapidly absorbed by PbO_2 with rise of temperature and production of SO_2 —4 Potassium iodide is decomposed with liberation of I —5 PbO_2 reacts with a dilute solution of potassium ferrocyanide to form K_2FeCy_6 provided the KOH produced in the reaction is neutralised by CO_2 , with conc potassium ferrocyanide solution in presence of KOH , K_2FeCy_6 is formed —6 By digesting PbO_2 with ammoniac solution, PbO , H_2O , and NH_4NO_3 are produced —7 Not acted on by cold nitric or sulphuric acid, with hot conc H_2SO_4 gives PbSO_4 and O —8 Cold conc hydrochloric acid in excess dissolves PbO_2 , producing a yellow liquid which evolves Cl on heating and gives a pp of PbCl_2 , alkalis, alkaline carbonates, and alkaline earth oxides and carbonates ppt PbO from this solution, the solution almost certainly contains PbCl_2 (*v Lead tetrachloride*, p 126) Hot HCl aq evolves Cl and forms PbCl_2 —9 A basic acetate derived from PbO , is said by Jacquelin (*J pr* 53, 152) to be obtained by dissolving red lead in glacial acetic acid at 40° and cooling, J gives the formula $\text{PbO} \cdot (\text{C}_2\text{H}_3\text{O}_2)_2$, [$\text{O} = 8$, $\text{C} = 6$] [old notation] to the crystals which form These crystals are unchanged in acetic acid, on drying between paper, or on adding water, they are resolved into PbO and acetic acid Similar salts derived from PbO , are obtained by dissolving red lead in very conc phosphoric and arsenic acids, but the salts are very unstable (*J l c. cf Red oxide of lead, Reactions*, No 6, p 130)—10 Heated with phosphorus trichloride, PbCl_2 , POCl_3 , and $\text{Pb}(\text{HPO}_3)_2$ are formed (Michaelis, *J pr* [2] 4, 449)—11 Heated in chlorine, bromine, and iodine, the compounds $\text{Pb}_2\text{Cl}_2\text{O}$, $\text{Pb}_2\text{Br}_2\text{O}$, and $\text{Pb}_2\text{I}_2\text{O}$, respectively, are obtained, heated in chlorine and air, bromine and air, and iodine and air, the products are $\text{Pb}_2\text{Cl}_2\text{O}$, $\text{Pb}_2\text{Br}_2\text{O}$, and $\text{Pb}_2\text{I}_2\text{O}$, respectively (Crosa a. Sigura, *C J* 33, 405)—12 PbO_2 reacts with alkalis to form compounds in which PbO forms the negative radicle, *eg* the salt K_2PbO_4 may be obtained from a solution in conc hot KOH aq (*v infra*, *Plumbates*)

HYDRATES OF LEAD PEROXIDE (1) $\text{PbO}_2 \cdot \text{H}_2\text{O}$ This hydrate is formed as a brown pp, by dis

solving PbO in molten KOH, heating in air for a considerable time, dissolving the K_2PbO_2 produced in cold water, and *exactly neutralising* by dilute H_2SO_4 (Carnegie, *C N* 60, 113). It is also probably obtained, at the positive electrode, by the electrolysis of strongly alkaline solutions of Pb salts (Becquerel, *A Ch* [3] 8, 405). By electrolysis of an alkaline solution of Pb Na tartrate, Wernicke (*P* 141, 109) obtained a lustrous blue-black film, which had the composition $PbO_2 \cdot H_2O$, SG 6 267. (2) According to Carnelley & Walker (*C J* 53, 85), ppd PbO, after drying in the air for 10 days has very nearly the composition $3PbO_2 \cdot H_2O$, at 230° this hydrate is changed to PbO_2 .

Plumbites.— PbO_2 reacts with acids as a basic peroxide forming salts corresponding with PbO , in some cases unstable salts derived from PbO_2 appear to be produced (*vs supra*, *Lead peroxide*, *Reactions* 8 and 9). PbO_2 also reacts with alkalis as an acidic oxide to form salts M'_2PbO_3 , known as *plumbites*. Fremy (*C R* 15, 1109) obtained colourless crystals of $K_2PbO_3 \cdot 3H_2O$ by dissolving PbO_2 in boiling very conc KOH, adding a little water, and placing over H_2SO_4 . Seidel (*J pr* [2] 20, 200) obtained the salt by adding PbO_2 to molten KOH containing a little water, dissolving the fused mass in water, and evaporating over H_2SO_4 *in vacuo*. The crystals form quadratic octahedra, $a:c = 1:1.2216$, they are decomposed by water with separation of PbO_2 . A corresponding Na salt is known. Solutions of these salts are said to yield pps of plumbites when added to solutions of various metallic salts. K_2PbO_3 is also produced by dissolving PbO in molten KOH and heating in air (Becquerel, *A Ch* 51, 504, Carnegie, *C N* 60, 113). Crum obtained a plumbite of Ca by digesting $Pb(NO_3)_2$ with CaO and bleaching powder (*A* 55, 213). For PLUMBATES *vs* KASSNER (*Ar Ph* 232, 375 [1894]).

Lead, oxybromides of Several oxybromides of Pb are known. The compound $PbO \cdot PbBr_2$ is formed by heating $PbBr_2$ in air so long as white fumes are evolved, also by digesting $PbBr_2$ with solution of Pb acetate. By heating PbO in Br vapour, Cross & Sigura obtained $Pb_2Br_3O_2$, and by heating the same oxide in a mixture of Br and air they obtained $Pb_2Br_3O_2$ (*C J* 33, 405), from PbO_2 they obtained $Pb_2Br_3O_2$ by heating in Br.

Lead, oxychlorides of $PbCl_2$ and PbO very readily combine when heated together to form oxychlorides from which HNO_3 dissolves out PbO .

$PbCl_2 \cdot PbO$ occurs native as *matlockite*, SG 7 21 (Greg, *P M* [4] 2, 120, Rammelsberg, *P* 75, 141), formed by heating $PbCl_2$ in air until fumes are no longer evolved, also by digesting freshly ppd $PbCl_2$ with cold Pb acetate solution (the oxychloride thus formed is $(PbCl_2 \cdot PbO)_2 \cdot H_2O$ according to Brandes, *A* 10, 273), also (with H_2O) by partial ppn of $PbCl_2$ by CaO (thus prepared it is used as a pigment (*Pattinson's white lead*)).

$PbCl_2 \cdot 2PbO$ occurs native as *mendipite*, in yellow white trimetric prisms, SG 7 to 7.1, formed, according to Ditté (*C R* 94, 1180), by gradually adding KOH to $PbCl_2$ suspended in water, or by adding KCl to $PbO \cdot xH_2O$.

$PbCl_2 \cdot 3PbO$. the hydrate with $4H_2O$ is

formed by adding NH_4Aq to $PbCl_2$ (Berzelius); also by mixing $NaCl$ with PbO , making into a paste with water, and allowing to stand, the product of this reaction, when washed and heated, gives a yellow powder, known as *Turner's yellow*, which is probably $PbCl_2 \cdot 3PbO$. The hydrate $PbCl_2 \cdot 3PbO \cdot H_2O$ was obtained by Voigt (*Chem Zeitung*, 13, 6⁶⁵) by dissolving PbO in $MgCl_2$ Aq, filtering, and evaporating.

$PbCl_2 \cdot 7PbO$ a lustrous, golden-yellow, crystalline mass, obtained by melting together 1 pt pure NH_4Cl and 10 pts pure PbO , pouring off from a little Pb (formed by the reducing action of NH_3 set free by the PbO acting on NH_4Cl), and allowing to cool, known as *Cassel yellow*.

By heating PbO in a mixture of Cl and air, Cross & Sigura obtained Pb_2Cl_3O (*C J* 33, 405), by heating PbO_2 in Cl the product was Pb_2Cl_3O , and by heating PbO in a mixture of Cl and air the compound Pb_2Cl_3O was obtained.

According to André (*A Ch* [6] 3, 104) $PbCl_2 \cdot PbO$, $PbCl_2 \cdot 2PbO$, and $PbCl_2 \cdot 3PbO$ are obtained by ppg $PbCl_2$ by KOH Aq.

Lead, oxycyanide of, *vs vol* 11 p 341

Lead, oxyiodides of Several oxyiodides of lead are known. $PbI_2 \cdot PbO \cdot H_2O$ is formed by adding $KIAq$ to excess of Pb acetate solution and digesting the pp in the liquid, it is a yellowish-white powder, insol water (Brandes, *A* 10, 269, cf Ditté, *C R* 92, 145). Other oxyiodides, described by Kuhn (*Ph C* 1847 593) and Denot (*J Ph* 20, 1) are $PbI_2 \cdot 2PbO \cdot H_2O$, $PbI_2 \cdot 3PbO \cdot 2H_2O$, and $PbI_2 \cdot 5PbO$. Cross & Sigura (*C J* 33, 405) describe the oxyiodides $Pb_{11}I_{10}O_{10}$, $Pb_2I_3O_3$, $Pb_3I_4O_4$, and $Pb_4I_5O_5$, obtained by heating PbO_2 and PbO , in I and air, and in I only.

Lead, phosphide of No phosphide of Pb has been isolated with certainty. Pelletier (*A Ch* [2] 13, 114) said that Pb takes up c 15 p c P when P is thrown on to melted Pb, or when Pb filings are strongly heated with glacial phosphoric acid, or $PbCl_2$ with P, but the experiments of Cloud (in Percy's laboratory) make it doubtful whether Pb and P combine. According to H Rose (*P* 24, 326) a brown pp, consisting of a phosphide of Pb, is obtained by passing PH_3 into Pb acetate solution.

Lead, salts of Compounds formed by replacing the H of acids by Pb. Pb forms one series of well marked salts, PbX_n , where $X = Cl, NO_3, \frac{1}{2}SO_4, \frac{1}{2}CO_3, \frac{1}{2}PO_4$, &c. $PbCl_2$ very probably exists in a solution of PbO_2 , or Pb_2O_3 , in cold conc $HClAq$, and $PbO(C_2H_3O_2)_2$ is said to have been isolated, these two salts belong to the series PbX_n , corresponding with the oxide PbO . Very many basic salts of Pb are known, and a considerable number of double salts. The formulæ of the Pb salts are determined from analyses, comparison with the salts and compounds of Sn, Ge, and Si, and from the vapour densities of $PbCl_2$ and $PbMe$. The following are the chief salts of lead (v CARBONATES, NITRATES, SULPHATES, &c.). *Antimonate*, *arsenate* and *ite*, *borate*, *bromate*, *carbonates*, *chlorate* and *ite*, *chromates*, *dithionate*, *hypophosphite*, *iodate*, *molybdate*, *nitrates* and *ites*, *pentathionate*, *perchlorate*, *periodates*, *phosphates* and *ites*, *sulphates* and *ites*, *selenate* and *ite*, *silicates*, *thiosulphate*, *trithionate*, *tungstates*, *urates*, *vanadates*.

Lead, selenide of, PbSe Occurs native as *clausthalite* in the Hartz, &c, the Pb being sometimes partly replaced by Co, Cu, Hg, Ag, &c, S G 7 to 88 (H Rose, P 2, 416, 3, 281, Stromeyer, P 2, 403, Kersten, P 46, 265) PbSe is produced by heating the constituents in the ratio Pb Se, it forms a porous, grey, soft mass (Berzelius), melted under borax small regular crystals are obtained, S G 8154 (Little, A 112, 212) Heated in air Se is vaporised, then a little PbSe, and a residue of basic selenite of Pb is left, cold HNO₃ dissolves Pb, leaving Se

Lead, selenocyanide of, Pb(SeCy)₂, v vol u p 348

Lead, silicofluoride of, Pb(BF₄)₂ Long prismatic crystals, by dissolving PbO in HBF₄ and evaporating to a syrup, partially decomposed by water or alcohol (Berzelius, P 2, 113)

Lead, sulphides of Besides PbS, which is a well marked compound, two subsulphides, Pb₂S and Pb₃S, probably exist, there are also indications of the formation of a persulphide

LEAD SULPHIDE (Lead monosulphide Plumbous sulphide) PbS

Occurrence—Native as *galena*, crystallised in monometric octahedra, and cubic and rhombic dodecahedra, S G 725 to 77 (v Neumann, P 23, 1)

Preparation—1 By mixing S with molten Pb—2 By heating PbO with excess of S—3 By the action of H₂S or an alkaline sulphide on Pb salts—4 By passing CS over Pb heated a little above redness, crystals of PbS are formed (Pb thiocarbonate seems to be also produced) (Gautier a Hallopeau, C R 104, 111)—5 Well formed crystals of PbS are obtained by passing H₂S into a solution of c 3 grams Pb(NO₃)₂ in 250 c c 10 p c HNO₃ at c 15°, if only c 1 p c HNO₃ is present the pp is amorphous (Muck, Z [2] 4, 211)—6 Crystalline PbS is produced by the action of PbO on thiourea (Reynolds, C J 45, 162) Addition of H₂S to a Pb salt in presence of HClAq sometimes produces a red pp of 3PbS PbCl₂, on warming and passing in more H₂S, PbS is formed—7 Winssinger (Bl [2] 49, 452) obtained an aqueous solution of colloidal PbS by ppg by H₂S a very dilute solution of a Pb salt, and dialysing, the solution was reddish brown

Properties—Lead grey crystalline solid, as prepared by fusion of Pb and S, S G 7505 (Karsten, S 65, 394) A brown black powder, as prepared by ppg by H₂S S G 6924 at 4° (Playfair a Joule, C J 1, 137), 677 (Schneider, J pr [2] 2, 91) Melts at full red heat out of contact with air, and is said to sublime unchanged Insol in dilute acids, caustic alkalis, and alkaline sulphide solutions

Reactions—1 Heated in air evolves SO₂, and forms Pb and P¹ SO₄, and some PbO (Descotils, A Ch [2] 55, 441)—2 Heated with *lead monoxide* forms Pb and SO₂, Pb and SO₂ are also produced by heating with *cad sulphate*, if little PbS is heated with much PbSO₄, the chief products are PbO and SO₂ (v LEAD, Formation, Nos 1 and 2, p 122)—3 Melted with *scrap iron* FeS and Pb are formed—4 Heated in *steam* gives H₂S, and at first PbO and afterwards Pb—5 Heated with *alkaline carbonates* half the Pb of

the PbS is separated—6 Boiled with *dilute nitric acid* Pb(NO₃)₂, S, and NO are produced, *fuming nitric acid* forms PbSO₄, and S, and sometimes Pb(NO₃)₂—7 *Conc hydrochloric acid* forms PbCl₂, and H₂S—8 *Aqua regia* forms PbCl₂, and PbSO₄—9 Slowly reacts with *chlorine* to form PbCl₂, and S₂Cl₂—10 By long *fusion with potash and nitre* Pb₂O₃ is produced (Carnegie, C N 60, 113)—11 Heated with lead, subsulphides (q v) Pb₂S and Pb₃S are formed

Combinations—With *lead chloride* to form the sulphochloride (q v) 3PbS PbCl₂

LEAD SUBSULPHIDES Pb₂S and Pb₃S Said to be formed by heating together PbS and Pb in the proper proportions (v Bredberg, P 17, 274) Pb₂S is also formed, according to Berthier (A Ch 3] 22, 240), by heating PbSO₄ in a crucible lined with charcoal

LEAD PERSULPHIDE Addition of K penta-sulphide to solution of a Pb salt gives a blood-red pp which is quickly changed, even in the liquid in which it is produced, into PbS and S Berzelius gives the formula PbS₅ to the persulphide

Lead, sulphochloride of 3PbS PbCl₂ Obtained as a red pp by passing a little H₂S into a dilute Pb solution acidified by HCl, Renisch (J pr 13, 130) obtained the compound by passing H₂S into a solution of 1 part Pb acetate in 200 parts water to which 20 parts HClAq, S G 1168, were added Also produced as a yellowish red solid by digesting freshly ppg PbS with PbCl₂ Aq Decomposed by H₂S with formation of PbS Boiling water partly dissolves out PbCl₂

Lead, sulphocyanide of Pb(SCy)₂, v vol u p 350 Combines with PbBr₂, and PbCl₂, v. *Lead bromosulphocyanide*, and *Lead chlorosulphocyanide*, pp 125, 127

Lead, thiocarbonate of PbCS Formed by adding solution of an alkali thiocarbonate to a Pb salt (cf THIOCARBONATES, vol 1 p 703)

M M P M

LEAD, WHITE White lead is a hydrocarbonate of Pb varying in composition, v vol u p 639

LEAD ORGANIC DERIVATIVES

Lead trimethyl salts Chloride PbMe₃Cl Formed by the action of boiling aqueous HCl on PbMe, (Cahours A Ch [3] 62, 257, A 122, 48) Long needles resembling PbCl₂ May be sublimed M sol boiling water and alcohol Converted into PbCl₂ by long boiling with HClAq

Bromide PbMe₃Br More soluble than the chloride

Iodide PbMe₃I Obtained by adding iodine to PbMe, till the odour becomes permanent White mass, crystallising from water in long colourless needles which may be sublimed Sl sol water, v sol alcohol On distillation with solid KOH it yields PbMe₃OH, a strong basic oil smelling like oil of mustard solidifying in prisms

Lead tetra-methyl, PbMe₄, (110°) (B) V D 952 (calc 925) S G ° 2034 From MeI and an alloy of lead (5 pts) and sodium (1 pt), or, better, from PbCl₂ and ZnMe₂ (Cahours) Colourless liquid, having a camphor like odour, insol water, sol alcohol and ether (Cahours) According to Butlerow it smells like strawberries or mould It does not unite directly with chlorine or iodine, but is decomposed thereby, e.g.

$\text{PbMe}_2 + \text{I}_2 = \text{PbMe}_2\text{I} + \text{MeI}$ Acids convert it into OH , and a salt of PbMe_2 .

Di-plumbic hexa ethide, Pb_2Et_6 . *Lead triethyl SG 2 1471* Formed by adding sodium (1 pt) to molten lead (3 pts) and mixing the cooled and powdered alloy with EtI in flasks provided with inverted condensers. When the first violent action has ceased the product is freed from EtI by distilling at 100° , and the residue extracted with ether (Klippel, *J pr* 81, 287, cf Löwig, *J pr* 60, 304, *A* 88, 318).

Properties — Yellowish mobile oil, insol water, \sqrt sol alcohol and ether. Decomposed on distillation. By exposure to light, or by prolonged boiling with water, it decomposes with separation of metallic lead. When exposed to the air in ethereal solution it absorbs O and CO_2 with formation of $(\text{PbEt}_2)_2\text{O}$ and $(\text{PbEt}_2)_2\text{CO}_2$. It combines with iodine forming PbEt_2I .

Lead triethyl salts *Chloride* PbEt_2Cl Obtained by adding BaCl_2 to a solution of $(\text{PbEt}_2)_2\text{SO}_4$ in alcohol, or by treating $(\text{PbEt}_2)_2\text{O}$, $(\text{PbEt}_2)_2\text{CO}_2$, or PbEt_2 with HCl . Beautiful long needles, giving off a pungent odour when heated, presently decomposing with separation of PbCl_2 and metallic lead — $\text{PbEt}_2\text{HgCl}_2$, white nacreous scales (from hot alcohol) — $(\text{PbEt}_2\text{Cl})_2\text{PtCl}_4$, copper-red crystals, sl sol water, m sol alcohol and ether.

Bromide PbEt_2Br Long needles (from ether).

Iodide PbEt_2I From Pb_2Et_6 and iodine, or from $(\text{PbEt}_2)_2\text{SO}_4$ and KI . Sol ether and very unstable, the ethereal solution quickly depositing PbI_2 .

Cyanide PbEt_2Cy From PbEt_2Cl and KCy in alcoholic solution at 100° . Prisms (from ether).

Hydroxide $\text{PbEt}_2(\text{OH})$ From the chloride by treatment with moist Ag_2O or by distillation with KOH . Needles, sl sol water, \sqrt sol alcohol and ether. Has strong alkaline reaction and caustic taste. Saponifies fats, ppts ferric, cupric, and argentic oxides from their salts. Ppts alumina and zinc oxide, the pp dissolving in excess of the precipitant. Expels NH_3 from its salts. Absorbs atmospheric CO_2 . Fumes with HCl . When heated it gives off white vapours which powerfully excite sneezing.

Carbonate $(\text{PbEt}_2)_2\text{CO}_3$ Small hard crystals, nearly insol water, sl sol alcohol and ether. Has a burning taste.

Nitrate PbEt_2NO_3 , unctuous crystalline mass, decomposed by heat with slight detonation. \sqrt sol alcohol and ether — $(\text{PbEt}_2)_2\text{SO}_4$, from the oxide and H_2SO_4 . White crystalline pp, nearly insol water, alcohol, and ether, \sqrt sol alcohol mixed with H_2SO_4 or HCl , from which solution it separates in octahedra.

Phosphate $(\text{PbEt}_2)_2\text{PO}_4$, stellate groups of crystals, \sqrt sol water, alcohol, and ether.

Sulphocyanide PbEt_2SCy crystals, sol water, alcohol, and ether.

The formate $\text{PbEt}_2\text{CHO}_2$, acetate $\text{PbEt}_2\text{C}_2\text{H}_3\text{O}_2$, butyrate $\text{PbEt}_2\text{C}_4\text{H}_7\text{O}_2$, oxalate $(\text{PbEt}_2)_2\text{C}_2\text{O}_4$, aq, tartrate $\text{PbEt}_2\text{C}_4\text{H}_4\text{O}_6$ (dried at 100°), and benzoate are crystalline.

Lead tetraethide, PbEt_4 . Mol w 323 (σ 200°), (152° at 190 mm) (B) SG 1.62.

Preparation — PbCl_2 is added to ZnEt_2 , as long as reaction occurs. The PbEt_4 is distilled

with steam $2\text{ZnEt}_2 + 2\text{PbCl}_2 = 2\text{ZnCl}_2 + 2\text{PbEt}_4$, and then $2\text{PbEt}_4 = \text{Pb} + \text{PbEt}_2$ (Buckton, *P M* [4] 18, 212, 17, 282, *A* 109, 218, 112, 220, Frankland & Lawrance, *C J* 35, 244).

Properties — Oil, not decomposed by water or by gaseous NH_3 , CO_2 , CO , C_2N_2 , NO , O , or H_2S . Partially decomposes at 200° .

Reactions — 1 Gaseous SO_2 reacts forming diethyl sulphone and lead ethyl sulphinate $\text{PbEt}_2 + 3\text{SO}_2 = \text{Et}_2\text{SO}_2 + (\text{EtSO}_2)_2\text{Pb}$ — 2 Iodine forms PbEt_2I and EtI — 3 Conc HCl forms PbEt_2Cl and ethane.

Di-plumbic hexa-iso-amylide, $\text{Pb}_2(\text{C}_5\text{H}_{11})_6$. Prepared like the corresponding Pb_2Et_6 , using isoamyl iodide (Klippel). Oil, with irritating vapour. Detonates with HNO_3 .

Lead tri-isoamyl salts *Chloride* $\text{Pb}(\text{C}_5\text{H}_{11})_3\text{Cl}$ from the oxide and HCl . White needles.

Iodide $\text{Pb}(\text{C}_5\text{H}_{11})_3\text{I}$ from $\text{Pb}_2(\text{C}_5\text{H}_{11})_6$ in ether by adding iodine [100°]. Needles, insol water — $\text{Pb}(\text{C}_5\text{H}_{11})_3\text{HgI}$, golden laminae, insol water, sl sol alcohol and ether — *Hydroxide* $\text{Pb}(\text{C}_5\text{H}_{11})_3\text{OH}$, viscid mass, insol water, sol alcohol and ether. Feebly alkaline, ppts ferric, but not cupric and silver salts.

Lead tetra-phenyl $\text{Pb}(\text{C}_6\text{H}_5)_4$, [225°] SG 22 1.530 Prepared by boiling 500 g of an 8 p.c alloy of sodium and lead with 500 g of bromo benzene and 20 c.c of acetic ether for sixty hours (Polis, *B* 20, 716, 3331). Small needles or dimetric prisms, $a:c=1.381$. Decomposes at 270° . \sqrt sol sl alcohol, ether, and HOAc , m sol benzene, CHCl_3 and CS_2 . Heated with HClAq at 230° it yields PbCl_2 , benzene, and chloro benzene.

Lead diphenyl salts *Chloride* PbPh_2Cl_2 Formed by passing chlorine into a solution of lead tetra phenyl in CS_2 , or by ppg $\text{PbPh}_2(\text{NO}_3)_2$ with KCl . White powder, insol alcohol and ether, \sqrt sl sol benzene.

Bromide PbPh_2Br_2 From lead di phenyl nitrate and KBr . White powder, which decomposes before fusion.

Iodide $\text{Pb}(\text{C}_6\text{H}_5)_2\text{I}_2$ [c 103°]. Formed by adding iodine to a solution of lead tetraphenyl in chloroform (Polis). Golden plates, sol chloroform, benzene, and alcohol.

Nitrate $\text{Pb}(\text{C}_6\text{H}_5)_2(\text{NO}_3)_2$ 2aq. Obtained by gradually adding lead tetra phenyl to boiling HNO_3 (SG 1.4). Small lustrous plates (from water). \sqrt sol hot water and alcohol. Detonates when heated. Boiling its aqueous solution produces a pp of the basic salt $\text{Pb}(\text{C}_6\text{H}_5)_2(\text{NO}_3)(\text{OH})$ as a white powder which detonates when heated.

Oxide $\text{Pb}(\text{C}_6\text{H}_5)_2\text{O}$ Obtained by boiling the nitrate with aqueous NaOH (Polis, *B* 20, 3332). White powder, insol alcohol, ether, and benzene.

Oxy cyanide $\text{Pb}(\text{C}_6\text{H}_5)_2\text{Cy}(\text{OH})$ From the nitrate in aqueous solution and KCy . White powder, insol water, alcohol, and ether.

Sulphocyanide $\text{Pb}(\text{C}_6\text{H}_5)_2(\text{SCy})_2$ Formed by adding ammonium sulphocyanide to an aqueous solution of the acetate. White powder, insol water and ordinary solvents.

Phosphate $(\text{PbPh}_2)_2(\text{PO}_4)_3$ Formed by adding sodium phosphate to an aqueous solution of the nitrate. White pp, insol. usual solvents.

Oxy-carbonate $(\text{PbPh}_2\text{OH})_2\text{CO}_3$. Ppd. as

a white insoluble powder by adding Na_2CO_3 to solutions of salts of lead diphenyl

Chromate $\text{Pb}(\text{C}_6\text{H}_5)_2\text{CrO}_4$ From the nitrate and $\text{K}_2\text{Cr}_2\text{O}_7$. Yellow pp, insol water
Sulphide $\text{Pb}(\text{C}_6\text{H}_5)_2\text{S}$ From the acetate and H_2S . Yellow prisms, sl sol alcohol, v sol benzene. Decomposes between 80° and 90°

Formate $\text{Pb}(\text{C}_6\text{H}_5)_2(\text{OHO})_2$, aq. From lead tetra phenyl and concentrated formic acid. Needles. Melts above 200° , with decomposition

Acetate $\text{Pb}(\text{C}_6\text{H}_5)_2(\text{C}_2\text{H}_3\text{O}_2)_2$, 2aq. From lead tetra phenyl and glacial HOAc (Polis, B 20, 3333). Prisms, v sol. water containing acetic acid. Melts at 193° when anhydrous

Lead tetra-*p*-tolyl $\text{Pb}(\text{C}_6\text{H}_4)_4$ [240?] S G 22 1433. Prepared by heating a mixture of 8 p.c. sodium lead alloy (300 g), *p* bromo toluene (120 g), toluene (40 g), and acetic ether (4 c.c.) for thirty hours in an oil bath. Repeated crystallisation of the product from benzene and alcohol yields lead tetra tolyl and di-*p* tolyl (A. Polis, B 21, 3424). Small needles. Decomposes at 254° . More sol. benzene, CS_2 and CHCl_3 than lead tetra phenyl. When heated with HCl at 200° it gives PbCl_2 and chloro toluene. Cold conc. HNO_3 causes decomposition with blackening, but on adding lead tetra tolyl to boiling nitric acid (S G 14) the products are lead di tolyl nitrate $\text{Pb}(\text{C}_6\text{H}_4)_2(\text{NO}_3)_2$ and nitro toluene

Lead di-*p*-tolyl salts

Chloride $\text{Pb}(\text{C}_6\text{H}_4)_2\text{Cl}_2$. Formed by passing Cl_2 into a solution of lead tetra tolyl in CS_2 . White powder, insol alcohol and ether, sl sol CHCl_3 , benzene, and CS_2 . Decomposed when heated. Converted into the corresponding nitrate by AgNO_3 in alcoholic solution

Bromide $\text{Pb}(\text{C}_6\text{H}_4)_2\text{Br}_2$. From $\text{Pb}(\text{C}_6\text{H}_4)_4$ in CS_2 and bromine. Resembles the chloride

Iodide $\text{Pb}(\text{C}_6\text{H}_4)_2\text{I}_2$. From $\text{Pb}(\text{C}_6\text{H}_4)_4$ and iodine, both dissolved in CS_2 . Yellow powder, more sol. chloroform and CS_2 than the chloride or bromide

Nitrate $\text{Pb}(\text{C}_6\text{H}_4)_2(\text{NO}_3)_2$, 2aq. Prepared as above. White powder composed of very slender needles, sol. water, containing HNO_3 , sl sol alcohol. Detonates when heated

Oxy nitrate $\text{Pb}(\text{C}_6\text{H}_4)_2(\text{OH})(\text{NO}_3)$. Formed by heating the nitrate with water, or by adding ammonia to a solution of the nitrate in dilute HNO_3 . White amorphous powder

Chromate $\text{Pb}(\text{C}_6\text{H}_4)_2\text{CrO}_4$. Insol yellow powder, ppd, by adding $\text{K}_2\text{Cr}_2\text{O}_7$ to a solution of the acetate

Sulphide $\text{Pb}(\text{C}_6\text{H}_4)_2\text{S}$. Formed by passing H_2S into a solution of the acetate. Transparent yellow plates (from alcohol benzene), sl sol alcohol and ether, v sol benzene, CS_2 , and CHCl_3 . Begins to turn brown at 90° and melts at 98° . It is decomposed by light

Formate $\text{Pb}(\text{C}_6\text{H}_4)_2(\text{CHO}_2)_2$. Formed from $\text{Pb}(\text{C}_6\text{H}_4)_4$ and formic acid. Beautiful white needles, which at 233° blacken and decompose

Acetate $\text{Pb}(\text{C}_6\text{H}_4)_2(\text{C}_2\text{H}_3\text{O}_2)_2$, 2aq. [183 5?] Formed by adding $\text{Pb}(\text{C}_6\text{H}_4)_4$ to boiling HOAc . Small white needles, more sol. dilute HOAc than the corresponding phenyl compound

LECANORIC ACID $\text{C}_{10}\text{H}_{16}\text{O}_7$. (a)-*Orsellic acid* *Diorsellic acid*. [168° cor] S 04 at

100° (Schunck) S (80 p.c. alcohol) 7° at 15° (Schunck), S, (ether) 4 at 20° (Hesse), 125 at 15° (Schunck). Discovered by Schunck in 1842 and extracted from several lichens of the genera *Lecanora*, *Varicolaria*, and *Roccella* (Schunck, A 41, 157, 54, 261, 61, 72, Roehleder & Heldt, A 48, 1, Stenhouse, A 68, 61, 70, 218, Strecker, A 68, 108, Laurent & Gerhardt, A Ch [3] 24, 310, Robiquet, A Ch 42, 236, Hesse, A 139, 22). Obtained by exhausting the lichens with ether, dissolving the greenish white crystalline residue left on evaporation in milk of lime, ppg the filtrate with H_2SO_4 , washing the pp with water, and recrystallising it from hot alcohol (Hesse). Stellate needles (containing aq). Almost insol cold water. Decomposed by heat with evolution of CO_2 . A solution of barium lecanorate is not decomposed by CO_2 . FeCl_3 colours its alcoholic solution dark purple red. An ammoniacal solution of lecanoric acid forms white pps with lead subacetate and with AgNO_3 , but the silver salt is quickly reduced. An alcoholic solution gives no pp with alcoholic solutions of lead acetate, HgCl_2 , or AgNO_3 , but with cupric acetate it gives an apple green pp. When a solution of lecanoric acid is boiled it gives orsellic acid $\text{C}_{10}\text{H}_8\text{O}_4 + \text{H}_2\text{O} = 2\text{C}_5\text{H}_4\text{O}_2$. A solution of barium lecanorate yields, on boiling, first barium orsellate, and finally orcin $\text{C}_8\text{H}_6\text{O}_4$ and BaCO_3 . An alcoholic solution yields, on boiling, orsellic ether. An ammoniacal solution acquires, on exposure to air, a splendid purple colour, through formation of orcein. Bleaching powder gives a red tint, quickly changing to brown

Salt — BaA'' small stellate needles

Di-bromo-lecanoric acid $\text{C}_{10}\text{H}_{12}\text{Br}_2\text{O}_7$ [179°] From lecanoric acid and Br in ether (Hesse). White crystals (from alcohol), insol water. FeCl_3 colours its alcoholic solution violet. Gives off CO_2 on fusion

Tetra-bromo lecanoric acid $\text{C}_{10}\text{H}_8\text{Br}_4\text{O}_7$ [157°] From lecanoric acid and excess of Br in ether. Pale yellow prisms (from alcohol), v sol alcohol, ether, and alkalis. FeCl_3 colours its alcoholic solution purple. Boiling baryta-water decomposes it

LECITHIN $\text{C}_{44}\text{H}_{88}\text{O}_6\text{PN}$ (Von Lippmann, B 20, 3201), $\text{C}_{44}\text{H}_{88}\text{O}_6\text{PNaq}$ (Diaconoff) *Protagon*. Occurs in the eggs and milt or soft roe of the carp and herring, the yolk of poultry eggs, the brain of man, sheep, and domestic fowl, bile of pigs, men, and oxen, retina of oxen, blood, yeast, milk, butter, radicles of sprouting lupin seeds, maize, peas, wheat, beet root, &c (Gobley, J Ph [3] 9, 1, 83, 161, 11, 409, 12, 5, 17, 401, 18, 107, 19, 406, 21, 241, 30, 241, 33, 161; Strecker, A 123, 356, Z [2] 4, 437, Kodweiss, A 59, 261, Diaconoff, Z [2] 4, 154, Liebreich, A 134, 29, Cahn, H 5, 215, Hoppe Seyler, H 2, 427, 3, 378, J 1866, 698, 744, Hermann, Z 1866, 250, Schmidt Mulheim, J Th 1883, 166, Schulze a Barbieri, J pr [2] 27, 358, H 13, 365, Heckel a Schlagdenhauffen, C R 103, 388, Copeman a Winston, J Physiol 10, 213).

Preparation — 1 Yolk of egg is extracted with alcohol ether, and an alcoholic solution of platinum chloride is added. A compound of leorhin and platinum chloride is ppd, and this is agitated with Ag_2O , the filtrate freed from silver by H_2S and evaporated (Strecker) — 2 Brain is

exhausted with ether, and the residue extracted with absolute alcohol at 40°. The alcoholic extract is corded at 0° and filtered, and the pp of lecithin and cerebrin collected, washed with alcohol, and treated with ether. The ethereal solution of lecithin is evaporated (Diaconoff) — 3 Beet root is extracted with ether alcohol, the ether evaporated and the residue dissolved in alcohol and ppd by platinum chloride. The pp is decomposed by H_2S (Lippmann).

Properties — Hygroscopic wax-like substance, which swells up in water and is v sol alcohol, ether, chloroform, and oils. Boiling with baryta water produces glycoero-phosphoric acid, neurine, and a fatty acid (stearic, oleic, or palmitic). According to Diaconoff lecithin from brain may be separated by dissolving in alcohol and cooling to -10° , into a stearo lecithin which separates and an oleo lecithin which remains in solution. According to Strecker the decomposition by baryta may be represented thus —

thus stearo lecithin would be $C_{11}H_{20}O_8NP$, while oleo lecithin would be $C_{11}H_{20}O_8NP$ and might be written

$(C_{15}H_{33}O_2)_2C_2H_5OPO(OH)OC_2H_4N(CH_3)_2OH$. The particular lecithin examined by Strecker appeared, however, to be $C_{15}H_{33}O_8NP$ or to contain one oleyl and one palmityl radicle in place of the two oleyls in the above formula. That the neurine is not present as a base appears from the observation that lecithin is hardly attacked by dilute (10 p c) sulphuric acid (Gilson, *H* 12, 585). The neurine salt of distearyl glycoero phosphoric acid appears therefore not to be a true lecithin (v GLYCERIN). According to Lippmann the base obtained by boiling beet root lecithin with baryta is sometimes neurine and sometimes betaine. The presence of lecithin enables a solution of glucose to absorb oxygen from the air in the same way as an alkaline solution of that sugar (Nencki & Sieber, *J pr* [2] 26, 17).

Salts — The hydrochloride is a waxy mass — $(C_{15}H_{33}O_8PN)_2PtCl_6$ yellow flocculent pp v sol ether, chloroform, and benzene, but ppd from these solutions by alcohol (Strecker) — $CdCl_2$ gives a pp in a solution of lecithin in ether-alcohol.

LEDITANNIC ACID $C_{15}H_{26}O_8$. Occurs in the leaves of the marsh wild rosemary (*Ledum palustre*) (Willkg, *A* 74, 363, Rochleder & Schwartz, *A* 74, 366, *Z* 1866, 382, Thal, *J* 1883, 1401). Prepared by ppg the alcoholic decoction of the leaves with water, and the filtrate with lead acetate. The pp is dissolved in dilute HOAc, filtered, heated to boiling, and ppd with lead subacetate. The pp is suspended in water and decomposed by H_2S , and the filtrate evaporated in a current of CO_2 . Reddish powder, v sol water and alcohol. $FeCl_3$ colours its aqueous solution dark green. Lead acetate and $SnCl_4$ give yellow pps. Boiling dilute H_2SO_4 forms ledixanthin but no sugar.

Ledixanthin $C_8H_{10}O_2$ is a reddish-yellow powder, v. sol alkalis. Its alcoholic solution

gives a reddish-brown pp with lead acetate. On dry distillation it yields pyrocatechin.

LEDUM OIL. An oil obtained by steam distillation from the leaves of *ledum palustre*. According to Willkg (*Sitz W* 9, 302) it consists of a terpene and of an oxygenated oil $C_{15}H_{26}O_2$. Grassmann (*Rep Pharm* 38, 53) obtained a volatile oil (1 pt) and ledum camphor (2 pts). Fröhde (*J pr* 82, 181) found the oil to be acid and to contain a terpene (160°) and an oxygenated oil (241°). According to Trapp (*Russ Zeit Pharm* 1874, 289) the oil when recently prepared is yellowish, viscid, lighter than water, and possesses a pungent odour, when exposed to air the greater part solidifies to a crystalline mass soluble in alcohol. The solution of this solidified oil (ledum camphor) in H_2SO_4 is turned violet by HNO_3 . Ivanoff (*Russ Zeit Pharm* 1876, 577) found ledum oil to consist of a white crystalline mass saturated with oil. By repeated crystallisation from alcohol white prisms of $C_{15}H_{26}O_2$ were obtained. These were insol water, v sol alcohol, ether, chloroform, and benzene, melted at 101° , boiled at 174° , and were dextrorotatory in alcoholic solution. According to Hjelt & Collan (*B* 15, 2500) ledum camphor melts at 101° , and has a vapour density 12.33 corresponding with the formula $C_{15}H_{26}O_2$ (calc 13.02), and sublimes in long white needles. Rizza (*J R* 19, 319) gives the following properties for ledum camphor, $C_{15}H_{26}O_2$ [101°], (292° 1 V), VD 8.10, and states that Ac_2O at 150° converts it into a sesquiterpene $C_{15}H_{24}$ (264°), SG \pm 935.

LEGUMIN v PROTEINS

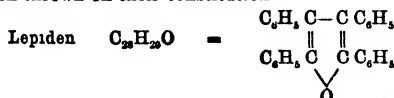

LEKENE C_2H_4 [79°] SG = 939. Forms the chief constituent of ozokerit or mineral wax, from which it is isolated by distilling the wax *in vacuo*, dissolving the distillate in benzene, and precipitating with absolute alcohol (Beilstein & Wiegand, *B* 16, 1547). White glistening crystals S (96 p c alcohol at 16°) = 0.105, S (benzene at 15°) = 8, sparingly sol in most other cold solvents, e sol hot benzene and chloroform, insol acetone. It decomposes on distillation under ordinary pressure, but can be distilled *in vacuo*. It is very stable towards oxidising agents.

LEMON OIL. Obtained by pressure from the peel of the fruit of *citrus medica*. Contains a terpene $C_{10}H_{16}$ (166°) (Blanchet & Sell, *A* 6, 281, Soubeiran & Capitaine, *A* 34, 317) or (175°) (Regnault, *J* 1863, 70, *A* 52, 171). SG 85 at 15° – 22° . The terpene is dextrorotatory, $[\alpha]_D = 109^\circ$ (Kanonnikoff, *Bn* 3, 299). According to Wallach (*A* 227, 290) oil of lemon contains pinene and hesperidene (cf Deville, *A* 71, 348, Oppenheim, *B* 5, 628). In examining the essential oil obtained by steam distillation from lemon peel, Tilden (*Ph* [3] 9, 654) found the SG to be 85.2 at 20° , and the rotation + 59° in a column 100 mm long. In this oil he found terbenzene $C_{10}H_{16}$, citrene $C_{15}H_{24}$ (constituting 70 p c of the whole), cymene (6 p c), a dextrorotatory body $C_{15}H_{26}O$ resembling terpineol (over 200°), a compound ether $C_{15}H_{24}O$ decomposed by heat into HOAc and $C_{10}H_{16}$, and $C_{15}H_{24}O$ (116°) Tilden & Dick, *C J* 57, 32). The citrene (176°) forms a terpene hydrate when treated with HNO_3 . Conc H_2SO_4 converts it into an inactive hydrocarbon (176°). Bouchardat & Lafont (*C R* 101, 383) find in essence of lemon a terpene $C_{10}H_{16}$ (178°) with a rotatory power + 105° which yields

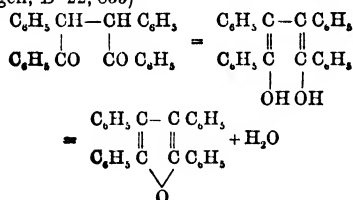

a solid inactive hydrochloride Flavitzky (*Bl* [2] 85, 171) found in a commercial sample of lemon oil ($[\alpha]_D = +60^\circ$) a levorotatory terpene (165°), S G 22 857, $[\alpha]_D = -29.8^\circ$ which formed a levorotatory hydrochloride $[\alpha]_D = -25.9^\circ$, but this was possibly an adulterant. The oil from the peel of *citrus bigamalia* contains a terpene (178°) S G 22 852 which is strongly dextro rotatory, and forms a crystalline hydrochloride $C_{10}H_{16} \cdot 2HCl$ (De Luca, *J* 1857, 481)

LEPARGYLIC ACID v AZELAIC ACID

LEPIDEN AND ITS DERIVATIVES Most of these complex compounds were first described by Zinin¹. It is only recently that light has been thrown on their constitution

(*Tetraphenylfurfuran*) (Zinin, *Z* 1867, 313, Japp a Klingemann, *B* 21, 2934 n, cf Dorn, *A* 153, 358) Formed, along with benzil and oily matters, when benzoil is heated with 1½ times its weight of conc hydrochloric acid (saturated at 8°) for 7-8 hours at 130° . The product is washed with ether, which removes the oil and benzil, after which it is recrystallised from boiling glacial acetic acid (Zinin). Also formed when bidesyl (hydro oxylepiden), or isobidesyl, is heated with conc hydrochloric acid for 2-3 hours at 130° - 140° (Maganini a Angeh, *B* 22, 855)

—Laminæ [175°] Volatilises at 220° . Insol water, sol 170 pts of boiling alcohol, 52 pts of ether at 17° , 28 pts of boiling glacial acetic acid, 8 pts of cold benzene. Boiling alcoholic potash is without action on it. Nitric acid or chromic acid oxidises it to 'acicular oxylepiden' $C_{28}H_{40}O_2$. Chlorine has the same action, but bromine converts it into dibromlepiden. With phosphorus pentachloride it yields dichlorlepiden

Chlorlepiden $C_{28}H_{38}ClO$ By treating an alcoholic solution of dichlorlepiden with sodium amalgam for 24 hours (Dorn, *A* 153, 355) — Large needles [143° - 146°], insol ether, sl sol alcohol, v sol benzene

Dichlorlepiden $C_{28}H_{36}Cl_2O$ Cannot be obtained by passing chlorine into a boiling solution of lepiden, as under these circumstances 'acicular oxylepiden' is formed (Zinin, *J R* 7, 893) By heating together equal weights of lepiden and phosphorus pentachloride (Zinin, *J R* 5, 22) — Needles [169°], sol 20 pts boiling

glacial acetic acid, 66 pts boiling alcohol (95° p c), v sol ether

A dichlorlepiden described by Dorn (*A* 153, 355), and stated by him to melt at 156° , is probably identical with the foregoing

Isodichlorlepiden $C_{28}H_{36}Cl_2O$ Formed, to gether with hydrodichloroxylepiden, by boiling an acetic acid solution of 'acicular dichloroxylepiden' [202°] (Zinin, *J R* 7, 331), or of 'sparingly soluble dichloroxylepiden', with zinc dust (Zinin, *J R* 7, 194) — Needles [166°], sol 174 pts boiling alcohol (95° p c), 12.5 pts boiling glacial acetic acid, sol ether. Oxidation converts it back into 'acicular dichloroxylepiden'

Pentachlorlepiden $C_{28}H_{34}Cl_5O$ By heating oxylepiden with excess of a mixture of phosphorus pentachloride and oxychloride for half an hour at 200° (Dorn, *A* 153, 355) — Indistinct crystals [186°], v sl sol alcohol, ether, and glacial acetic acid, v sol benzene

Hexachlorlepiden $C_{28}H_{32}Cl_6O$ By heating dichloroxylepiden with the foregoing mixture for 1 hour at 200° (Dorn) — Yellow amorphous substance [80° - 90°], v sol alcohol, ether, and benzene

Octochlorlepiden $C_{28}H_{30}Cl_8O$ By heating dichloroxylepiden with the foregoing mixture for 7 hours at 210° (Dorn) — Orange yellow amorphous substance [97°], v sol alcohol, ether, and benzene

Dibromlepiden $C_{28}H_{38}Br_2O$ Prepared by heating a solution of lepiden in acetic acid with bromine (Zinin, *Z* 1867, 315) Formed, along with hydrodibromoxylepiden, when 'acicular dibromoxylepiden' is treated with zinc and acetic acid (Zinin, *J R* 7, 330) — Laminæ (from acetic acid) [190°] (Zinin), [185°] (Berlin), sol 480 pts alcohol (94° p c), 44 pts boiling, and 66 pts cold, acetic acid, 50 pts ether

Oxylepiden $C_{28}H_{40}O_2$ Zinin has prepared three isomeric oxylepidens, which he distinguishes as 'acicular oxylepiden', 'tabular oxylepiden', and 'octahedral oxylepiden'

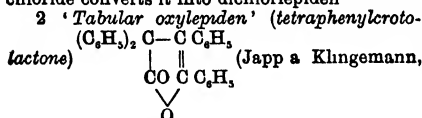

1 'Acicular oxylepiden' (dibenzoylstilbene)

$C_6H_5-CO-CO-C_6H_5$, 854, cf Japp a Klingemann, *C S Pr* 1889, 136) By oxidising lepiden with nitric acid (Zinin, *Z* 1867, 314) By treating thionessal $C_{28}H_{40}S$ (Berlin, *A* 153, 131) or toallyl sulphide $C_{28}H_{40}S_2$ (Dorn, *A* 153, 352) with hydrochloric acid and potassium chlorate By digesting benzoil with dilute sulphuric acid (Limpnich a Schwanert, *B* 4, 337) In order to prepare it, 1 pt of lepiden is suspended in 10 pts of boiling glacial acetic acid, and a mixture of 1 pt of acetic acid with 3 pts of nitric acid (S G 15) is added (Zinin, *lc*) — Yellow needles [220°], insol water, almost insol ether, sol 200 pts of boiling alcohol (94° p c) and 22 pts boiling glacial acetic acid, v sol benzene When heated to 340° it is converted into 'tabular oxylepiden' along with a little 'octahedral oxylepiden' Chromic anhydride in acetic acid solution oxidises it to dioxylepiden $C_{28}H_{40}O_3$. Zinc and acetic acid reduce it to lepiden Heating with hydriodic acid has the same effect (Dorn), also distillation with zinc dust (Berlin) In the formation of lepiden by reduction, the oxylepiden is probably first converted into hydro oxylepiden, which then parts with water, yielding lepiden

¹ Zinin's work appeared for the most part in the *Journal of the Russian Chemical Society*. The author of the present article is indebted, for his account of this portion of the subject, to Beilstein's *Handbuch der organischen Chemie*.

(*v supra*). Sodium amalgam, acting on the acetic acid solution, reduces it to hydroxy-lepiden $C_{28}H_{42}O_2$ (Zinnin). When heated with benzoin it is reduced to lepiden, whilst the benzoin yields benzil (Lamprecht a Schwanert, *B 4*, 388). Alcoholic ammonia at 200° converts it into a mixture of two imides of the formula $C_{28}H_{41}NO$ —one derived from 'acicular,' the other from 'tabular,' oxylepiden—whilst with methylamine it yields a methylimide $C_{28}H_{41}NO$ [161°] (Klingemann a Laycock, *private communication*). Heating with phosphorus pentachloride converts it into dichlorlepiden.

C S Pr 1889, 187) By heating 'acicular oxylepiden' to 340° and recrystallising the product, first from ether and afterwards from alcohol Tabular crystals are deposited first, then microscopic octahedra of the third modification (Zinnin, *J R* 5, 16). Tabular crystals [136°], insol water, sol 14.5 pts boiling alcohol (95 p c), and in its own weight of boiling glacial acetic acid. Dissolves readily in hot alcoholic potash solution (distinction from 'octahedral oxylepiden'), forming a salt of oxylepidenic acid $C_{28}H_{42}O_2$ (*infra*). Zinc and acetic acid are without action on it, but sodium and boiling amyl alcohol reduce it to tetraphenylbutyrolactone $C_{28}H_{42}O_2$. Alcoholic ammonia at 200° converts it into an imide $C_{28}H_{41}NO$, with alcoholic methylamine at 150° it yields the methylamide of oxylepidenic acid $C_{28}H_{41}O_2(NHCH_3)$. When heated with phosphorus pentachloride at 200° it forms chloroxy-lepiden $C_{28}H_{41}ClO_2$.

3 'Octahedral oxylepiden' Only 2 p c of this compound is formed when 'acicular oxylepiden' is heated to 340°. Most readily obtained by boiling 'acicular oxylepiden' with an alcoholic solution of caustic potash or caustic soda. Four parts of 'acicular oxylepiden' are boiled for 12–15 hours with 60 parts of alcohol (95 p c) and 3 parts of caustic soda, employing a reflux condenser. The product is washed successively with alcohol, water, and ether, and is finally recrystallised from boiling acetic acid (Zinnin, *J R* 7, 186, *J* 1875, 409). Yellowish, microscopic octahedra [232°]. Sol 76 parts boiling glacial acetic acid, almost insol alcohol. When heated to incipient boiling it is totally converted into 'tabular oxylepiden'. Boiling the acetic acid solution with zinc reduces it to hydroxy-lepiden, part of which loses water, yielding lepiden. A solution of chromic anhydride in acetic acid oxidises it to isodichlorlepiden $C_{28}H_{42}O_2$. Alcoholic potash is without action on it.

As regards the constitution of 'octahedral oxylepiden,' it is probable that this compound is a stereometric isomeride of 'acicular oxylepiden,' the latter representing the *maleoid*, the former the *fumaroid* form of dibenzoyl stilbene.

(Maleoid dibenzoylstilbene) (Fumaroid dibenzoylstilbene)

(Japp a Klingemann, *C S Pr* 1889, 188) Both yield on reduction the same hydro oxylepiden (bidesyl)

which may be converted by dehydration into lepiden.

The three oxylepidens yield by destructive distillation the same so called *isolepiden* $C_{28}H_{42}O$ (*infra*).

Chloroxy-lepiden $C_{28}H_{41}ClO_2$. By heating 'tabular oxylepiden' with a mixture of phosphorus pentachloride (1 part) and phosphorus trichloride ($\frac{1}{2}$ part) at 180°–200° (Zinnin, *J R* 5, 21—Crystals [185°], sol 22.8 parts boiling glacial acetic acid.

Dichloroxy-lepiden $C_{28}H_{41}Cl_2O_2$. 'Acicular dichloroxy-lepiden' is obtained by heating lepiden with four times its weight of phosphorus pentachloride and treating the product with water (Zinnin, *J R* 5, 23). By the oxidation of dichlorlepiden [169°] (Zinnin, *J R* 7, 332, *J* 1876, 426)—Needles [202°], sol 146 parts cold, 13.7 parts boiling acetic acid, 90 parts boiling ether. When boiled with zinc and acetic acid it yields a mixture of hydrodichloroxy-lepiden and isodichlorlepiden [166°].

When the foregoing 'acicular dichloroxy-lepiden' is heated to near its boiling point it is converted into a mixture of two new isomeric dichloroxy-lepidens, which may be separated by the difference in their solubility in ether. 'Readily soluble dichloroxy-lepiden,' which forms the chief product, is very soluble in alcohol, ether, and acetic acid, and is deposited from these solutions as a soft resin. Alcoholic caustic potash converts it into a salt of dichloroxy-lepidenic acid $C_{28}H_{42}Cl_2O_2$. The other isomeride, 'sparingly soluble dichloroxy-lepiden,' is best prepared by boiling 4 parts of 'acicular dichloroxy-lepiden' with three parts of caustic soda and 40 parts of alcohol for from 20 to 24 hours. It forms a granular powder consisting of microscopic prisms [230°], almost insol alcohol and ether, sol 36 parts boiling glacial acetic acid. Boiling with acetic acid and zinc converts it into isodichlorlepiden [166°] (Zinnin, *J R* 7, 191).

These three compounds, as their mode of formation and reactions denote, are to be regarded as dichlor substitution products of 'acicular,' 'tabular,' and 'octahedral' oxylepiden respectively.

A fourth *dichloroxy-lepiden* has been obtained by Dorn (*A* 153, 353) by treating *dichlorthionessal* $C_{28}H_{41}Cl_2S$ with hydrochloric acid and potassium chlorate—Small needles [178°], readily sol alcohol, benzene, and glacial acetic acid. Not attacked by alcoholic potash at 150°. Zinc and acetic acid convert it into a dichlorlepiden [156°] (*v supra*), whilst with hydriodic acid at 100° it yields dichlorlepiden, lepiden, and oxylepiden (?).

Dibromoxy-lepiden $C_{28}H_{41}Br_2O_2$. Three dibromoxy-lepidens, corresponding with the first three of the foregoing dichloroxy-lepidens, have also been described by Zinnin (*J R* 7, 329, *J* 1876, 425). In their modes of preparation, properties, and reactions, they resemble the chlorine compounds. 'Acicular dibromoxy-lepiden' is obtained either by brominating 'acicular oxylepi-

den' or by oxidising dibromolepiden in acetic acid solution with nitric acid. Needles [222°], sol 40 parts boiling acetic acid. Heated above its melting point it yields two isomeric dibromoxyepidenes—'readily soluble dibromoxyepiden', which is resinous, v sol alcohol, ether, and acetic acid, and is converted by alcoholic caustic potash into a salt of dibromoxyepidenic acid $C_{22}H_{22}Br_2O_2$, and 'sparingly soluble dibromoxyepiden'. This latter is more easily obtained by boiling the acicular modification with a quantity of alcoholic potash insufficient to dissolve it. Crystallises from alcohol in lemon yellow rhombic tables [239°], almost insol ether, sol 66 parts boiling acetic acid and 1,000 parts boiling alcohol (95 p c). Heated above its melting point it is converted into 'readily soluble dibromoxyepiden' (Zinnin, *J R* 7, 329, *J* 1876, 425).

Both 'acicular' and 'sparingly soluble' dibromoxyepiden, when reduced with zinc and acetic acid, yield the same hydrodibromoxyepiden (dibromidesyl), part of which undergoes dehydration, forming dibromlepiden [190°].

Hydroxyepiden (*Bidesyl*)

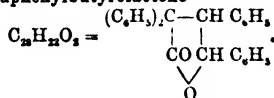

$C_{22}H_{22}O_2 =$ $C_6H_5 \cdot CO \quad CO \cdot C_6H_5$ (Magnanini & Angeli, *B* 22, 853) Formed, along with lepiden, by the action of zinc and acetic acid on 'octahedral oxyepiden', or of sodium amalgam on 'acicular oxyepiden'. The product of the reaction is ppt with water and treated with ether, which dissolves only the lepiden (Zinnin, *J R* 7, 188, *J* 1875, 409). By the action of desyl bromide, $C_6H_5 \cdot CHBr \cdot CO \cdot C_6H_5$, on sodium deoxybenzoin, or of iodine on sodium deoxybenzoin

$C_6H_5 \cdot CO \quad CO \cdot C_6H_5$ (Knovenagel, *B* 21, 1358) —Long flat needles (from acetic acid), [251°] (Zinnin), [254°–255°] (Knovenagel, also Magnanini & Angeli). Almost insol cold alcohol and ether, sol 112 pts boiling acetic acid, sol hot benzene. Heated with hydrochloric acid at 130°–140° it parts with water, yielding lepiden (Magnanini & Angeli, *B* 22, 853).

Tetraphenylbutyrolactone

By treating a solution of 'tabular oxyepiden' (tetraphenylbutyrolactone) in boiling amyl alcohol with sodium (Klingemann & Laycock, *private communication*) —Microscopic, white needles [221°], sol boiling, sl sol cold, alcohol.

Hydrodichloroxyepiden $C_{22}H_{22}Cl_2O_2$. Formed, along with dichlorlepiden, when 'sparingly soluble dichloroxyepiden' is boiled for a long time with zinc and 'acetic acid, or, more readily, by boiling an alcoholic solution of 'acicular dichloroxyepiden' with sodium amalgam, keeping the liquid acid with acetic acid (Zinnin, *J R* 7, 195, *J* 1875, 413). —Flat needles (from acetic acid) [261°], insol alcohol and ether, sol 205 pts boiling acetic acid.

Hydrodibromoxyepiden $C_{22}H_{22}Br_2O_2$. By the action of zinc and acetic acid on 'acicular' or 'sparingly soluble' dibromoxyepiden (Zinnin,

J R 7, 330, *J* 1876, 425) —Slender needles, v sl sol alcohol and ether, sol 172 pts boiling acetic acid.

Dioxyepiden $C_{22}H_{22}O_2$. By warming 25 pts of 'acicular oxyepiden', suspended in 20 pts of acetic acid, with a solution of 12–15 pts of chromic anhydride dissolved in 150 pts of acetic acid (Zinnin, *Z* 1871, 483) —Rhombic tables [157°], sol 24 pts boiling alcohol (95°). Reducing agents are without action on it. By further action of chromic anhydride it yields benzil and benzoic acid. Alcoholic potash hydrolyses it into deoxybenzoin and benzoic acid.

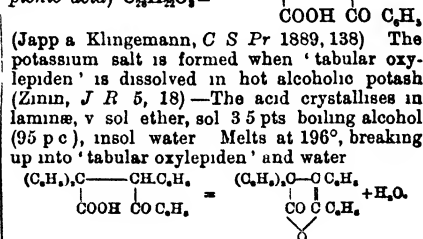

Isodioxyepiden $C_{22}H_{22}O_2$. By boiling 'octahedral oxyepiden' with a solution of chromic anhydride in acetic acid (Zinnin, *J R* 7, 190, *J* 1875, 410) —Laminæ [164°], sol 10 pts boiling alcohol, less sol ether, sol 4 pts boiling acetic acid. Boiling alcoholic potash is without action on it (distinction from foregoing isomeride).

Oxyepidenimide $C_{22}H_{21}NO$. By heating 'acicular oxyepiden' with alcoholic ammonia for 5 hours at 200°, it yields a mixture of oxyepidenimide and the isomeric tetraphenylpyrrolone. The oxyepidenimide is separated by means of its greater solubility in alcohol (Klingemann & Laycock, *private communication*) —Yellow prisms (from benzene) [180°–182°]. Heated to 310° it changes into tetraphenylpyrrolone (*v infra*).

Oxyepiden methylimide $C_{22}H_{21}O(NCH_3)$. By heating 'acicular oxyepiden' with an alcoholic solution of methylamine for 2 hours at 200° (K. & L.) —Small pale yellow plates [161°] from alcohol, well shaped crystals from carbon bisulphide. V sol benzene, readily sol carbon bisulphide, moderately sol boiling alcohol.

Oxyepidenic acid (*Benzoyl triphenyl pro*)
 $(C_6H_5)_3C - CH \cdot C_6H_5$
ponic acid) $C_{22}H_{22}O_2 =$

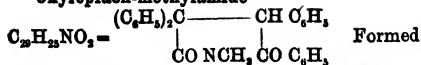

The so called *isoxylepidenic acid* described by Zinnin (*J* 1877, 397) is identical with the foregoing (Japp & Klingemann, *C S Pr* 1889, 139).

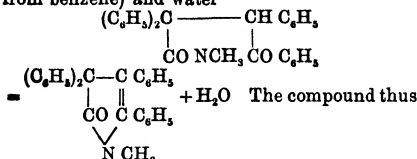

Tetraphenylpyrrolone
 $(C_6H_5)_3C - C \cdot C_6H_5$
 $C_{22}H_{21}NO =$ $\begin{array}{c} || \\ CO \quad C_6H_5 \\ | \\ NH \end{array}$ Formed, along

with the isomeric oxyepidenimide, when 'acicular oxyepiden' is heated with alcoholic ammonia at 200°. By heating oxyepidenimide to 310° as sole product when 'tabular oxyepiden' is heated with alcoholic ammonia at 200° (Klingemann & Laycock) —Small pale yellow plates [208°], sparingly sol alcohol.

Oxylepiden-methylamide

when 'tabular oxylepiden' is heated with an alcoholic solution of methylamine at 150° $\text{C}_{22}\text{H}_{22}\text{O}_2 + \text{NH}_4\text{CH}_3 = \text{C}_{22}\text{H}_{22}\text{NO}_2$ (Klingemann a Laycock) — Yellowish laminae [287°] from acetic acid, short needles from alcohol. Sol boiling alcohol, more sol boiling acetic acid. Decomposed by distillation *in vacuo* into methyl-tetraphenylpyrrolone (prismatic crystals [158°] from benzene) and water

formed appears to be isomeric, not identical, with oxylepiden-methylamide (K a L)

Dichloroxyepidenic acid $\text{C}_{22}\text{H}_{20}\text{Cl}_2\text{O}_2$. By dissolving 'readily soluble dichloroxyepiden' in boiling alcoholic potash (Zinn, *J R* 7, 191, *J* 1875, 411) — Rhombic laminae [182°], from acetic acid. Sol 16 pts boiling acetic acid. Heated to 200° it parts with 1 mol water, and is reconverted into 'readily soluble dichloroxyepiden'.

Dibromoxyepidenic acid $\text{C}_{22}\text{H}_{20}\text{Br}_2\text{O}_2$. By dissolving 'readily soluble dibromoxyepiden' in boiling alcoholic potash (Zinn, *J R* 7, 330, *J* 1876, 425) — Six sided laminae from acetic acid.

So called isolepiden and its derivatives — Under the name of *isolepiden*, Zinn (*J R* 5, 20) has described a compound which he obtained by the destructive distillation of oxylepiden, and which he regarded as isomeric with lepiden. Japp a Klingemann have, however, shown (*C S Pr* 1889, 139) that this compound has the formula $\text{C}_{27}\text{H}_{20}\text{O}$, instead of $\text{C}_{22}\text{H}_{20}\text{O}$, and that it is formed from oxylepiden with elimination of carbonic oxide according to the equation

The name 'isolepiden' is consequently inappropriate, but will be retained here, as the constitution of the compound is unknown, and a systematic name cannot be given. The formulae of the various hydro 'isolepidens' and oxy 'isolepidens' described by Zinn must also be written with 27 instead of with 22 atoms of carbon, although these compounds have not yet been re-investigated.

Isolepiden $\text{C}_{27}\text{H}_{20}\text{O}$ (Japp a Klingemann, *lc*) By the destructive distillation of oxylepiden (Zinn, *J R* 5, 20, cf preceding paragraph) The three oxylepidens all yield this compound on distillation, but in reality it is only 'tabular oxylepiden' which yields it, as the other two oxylepidens are previously transformed into 'tabular oxylepiden' at the temperature of the reaction. The distillate is washed with ether and then recrystallised, first from alcoholic potash, afterwards from alcohol. The ether extracts a little 'tabular oxylepiden,' which is carried over undecomposed (Japp a Klingemann, *C S Pr* 1889, 139) — Isolepiden forms yellow tabular crystals [150°]. Decomposes on redistillation. Sol 18 pts boiling alcohol (95 p c), and in 2 pts boiling acetic acid (Zinn, *J* 1877,

394). Not attacked by alcoholic potash. It is reduced by zinc dust and acetic acid to dihydro isolepiden $\text{C}_{27}\text{H}_{22}\text{O}$, and by sodium amalgam to tetrahydro isolepiden $\text{C}_{27}\text{H}_{24}\text{O}$. Oxidising agents convert it into oxy isolepiden, and ultimately into a mixture of benzophenone and benzil.

Dihydro-isolepiden $\text{C}_{27}\text{H}_{22}\text{O}$. By reducing a solution of isolepiden in from 5 to 6 pts of acetic acid with zinc dust. The product is poured into water, and the pp is washed with ether and recrystallised from alcohol (Zinn, *J* 1877, 394) — Small rectangular prisms [182°]. Sol 12.5 pts boiling alcohol (95 p c), v sl sol ether.

Tetrahydro isolepiden $\text{C}_{27}\text{H}_{24}\text{O}$. By the action of sodium amalgam on a boiling alcoholic solution of isolepiden (Zinn). Separates from ether as a soft resinous mass which soon becomes crystalline [182°]. Readily sol. alcohol and acetic acid, less sol ether. Chromic anhydride oxidises it in acetic acid solution, even in the cold, to dihydro isolepiden.

Oxyisolepiden $\text{C}_{27}\text{H}_{20}\text{O}_2$. Three pts of isolepiden are dissolved in 40 pts of acetic acid, and oxidised with a solution of 3 pts of chromic anhydride in 30 pts of acetic acid (Zinn, *J* 1877, 395) — Short slender needles [161°]. Sol 40 pts boiling, and 600 pts cold alcohol, and in 4 pts boiling acetic acid. Boiling alcoholic potash is without action on it. Zinc and acetic acid reduce it to dihydro isolepiden. Excess of chromic acid oxidises it, in acetic acid solution, to benzophenone as chief product, together with benzil and benzoic acid.

Oxy isolepiden, like oxylepiden, may be converted into isomeric compounds. Thus, when it is boiled with a quantity of alcohol or alcoholic potash insufficient to dissolve it, it is transformed into *cuneiform oxy isolepiden* [162°]. When this is heated above its melting point, or when ordinary oxy isolepiden is distilled, *tabular oxy-isolepiden*, a third isomeride, is formed. Rhombic tables [152.5°] from acetic acid. Sol 13.5 pts boiling acetic acid, 80 pts boiling alcohol. F R J

LEPIDINE v (Py 1) MFTHYL QUINOLINE

LEUCANILINE is described under TRIAMIDO DI PHENYL TOLYL METHANE.

Para-leucaniline is described as TRIAMIDO-TRI PHENYL METHANE.

LEUCAURIN v TRI OXY TRI PHENYL MFTHANIC

LEUCATROPIC ACID $\text{C}_{17}\text{H}_{12}\text{O}_3$ [74°]. Occurs in belladonna (Kunz, *Ar Ph* [3] 23, 722). Minute satiny needles. Insol cold, m sol boiling water, and alcohol.

LEUCINES v PROTEIDS

LEUCIC ACID Described as OXY HEXOIC ACID.

LEUCINDIGO v INDIGO

LEUCINE $\text{C}_6\text{H}_7\text{NO}_2$ i e

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{H}$ a *Amido n-hexoic acid*. Mol w 131 [170°] (Schwanert) S G 12 1 293 (Engel a Vilmain, *Bl* [2] 24, 279) S 22 at 18° (Schulze, *H* 9, 254), 37 in the cold (Zollkofer). S (alcohol of S G 828) 152 in the cold (Mulder). S (96 p c alcohol) 096 in the cold (K). S (98 p c hot alcohol) 125 (K). $[\alpha]_D = +14.1^\circ$ in a 15 p c HCl solution, $+5.6^\circ$ in a 25 p c solution in NH_4Aq (Reese, *A* 242, 11). Discovered by Proust (*A Ch* [3] 10, 40) as a product of the putrefaction of cheese, and called 'caseous oxide'. Braconnot

(*A Ch* [2] 18, 119) found it among the products of the action of H_2SO_4 on animal substances Mulder (*J pr* 16, 290) showed the two substances thus obtained were identical

Occurrences—In old cheese (Proust), in fresh calf's liver (Liebig, *Chem Briefe*, ed 3, 453), in diseased but not in healthy human liver (Frerichs & Stadel, *J* 1854, 675, 1856, 702, 1858, 550), in the tissue of the lungs (Cloetta, *A* 92, 289), in the thymoid and thyroid glands, and in the pancreas (Gorup-Besanez, *A* 98, 7, Radziejewsky, *Z* 1866, 416), in the brain of oxen (W Muller, *A* 103, 131), in the pancreas of oxen (Scherer, *J* 1859, 610), in the liver and urine in cases of typhus, smallpox, leucæmia, and poisoning by phosphorus (Salkowsky, *J Th* 1880, 457, Valentiner, *J* 1854, 675, Sotnitschewsky, *H* 3, 391), in the stomachs and intestines of the pupæ of butterflies (Schwarzenbach, *J* 1857, 538), in *Agaricus muscarius* (Ludwig, *J* 1862, 516), in the juice of vetches germinated in the dark (Gorup Besanez, *B* 7, 146, cf Cossa, *G* 5, 314), in *chenopodium album* in young pumpkin plants (Schulze a Barbieri, *B* 11, 1233), and in beet root molasses (Lippmann, *B* 17, 2837)

Formation—1 In the putrefaction of proteids and gelatin (Bopp, *A* 69, 20) and by boiling these substances with dilute H_2SO_4 , or by fusing them with potash (Hinterberger, *Sitz W* 9, 450, *A* 71, 75, Zollikofer, *A* 82, 174, Gossmann, *A* 91, 130, Leyer a Koller, *A* 83, 332, Schlossberger, *Z* 1860, 424, Erlenmeyer a Schoffer, *Z* 1859, 315, Hochstetter, *J pr* 29, 36, Ritt hausen a Kreuzler, *J pr* [2] 3, 307)—2 In the pancreatic digestion of gelatin (Nencki, *B* 7, 1593, Jeanneret, *J pr* [2] 15, 353)—3 By acting on a bromo hexoic acid with ammonia (Hufner, *J pr* [2] 1, 6, *Z* [2] 4, 391, 616)

Preparation—Horn shavings (2 lbs) are boiled with H_2SO_4 (5 lbs) and water (13 lbs) for 24 hours with inverted condenser The product is mixed with lime, filtered, and evaporated to a smaller bulk (12 lbs) Oxalic acid is then added to acid reaction, and the liquid filtered and evaporated till a crystalline film forms on the surface Leucine mixed with tyrosine is deposited in groups of yellowish laminae On recrystallisation from water tyrosine is deposited first, and the mother liquor is then decoloured by animal charcoal and evaporated The leucine is recrystallised from alcohol (Schwanert, *A* 102, 221, cf Hinterberger, *A* 71, 72 Waage, *A* 118, 295) Leucine may be detected and isolated by means of its sparingly soluble copper salt ($C_6H_{11}NO_2$)₂Cu, although the precipitation of this salt is hindered by free acids and by some organic bodies (Hoffmeister, *Sitz W* 75, 469)

Properties—Soft nacreous scales (from alcohol) resembling cholesterol It may be sublimed (Mulder) Decomposed on fusion, giving amylinine, CO_2 , and NH_3 Lævotatory (Lewkowitch, *B* 17, 1439, cf Mauthner, *H* 7, 223) Sol water and alcohol, insol ether Its solubility in water is increased by the presence of acetic acid or an alkaline acetate When heated with baryta water at 160° it becomes inactive. The inactive leucine is changed to an active variety, lævotatory when dissolved in aqueous HCl, by the action of *Penicillium glaucum* (Schulze a Bosshard, *B* 18, 388).

Reactions—1 An alkaline solution exposed to the action of ozone yields CO_2 , butyric acid, and NH_3 (Gorup-Besanez, *A* 125, 210)—2 Chlorine passed into water in which leucine is suspended forms CO_2 and valerionitrile, as well as chloro valerionitrile (Schwanert) Chlorine passed into an alkaline solution of leucine forms oxy-hexoic acid—3 Nitrous acid converts it into a oxy hexoic (leucic) acid—4 Distillation with MnO_2 and dilute H_2SO_4 yields CO_2 and valerionitrile—5 Distillation with water and PbO_2 yields butyric aldehyde and NH_3 (Liebig, *A* 70, 313)—6 Aqueous $KMnO_4$ yields NH_3 , oxalic acid, and valeric acid (Neubauer, *A* 106, 59)—7 Potash fusion gives NH_3 , hydrogen, and potassium valerate (Liebig, *A* 57, 127)—8 When heated with fuming HNO_3 at 140° it gives hexoic acid and ammonia (Hufner)—9 With KOH (2 mols) and MeI (3 mols) it forms potassium di methyl amido-hexoate methyl iodide $C_6H_{11}(NMe_2)CO_2K$, which, when heated with moist Ag_2O , yields methylamine, a salt $C_6H_{11}O_2K$, and potassium leucinate $C_6H_{11}O_2K$ (Körner a Menozzi, *G* 13, 353)—10 Leucine gives off more nitrogen when its solution is decomposed by $NaBrO$ in presence of NH_3 , than when the NH_3 is absent (E Schulze, *J pr* [2] 31, 236)

Salts— $HA \cdot HCl$ crystals, v sol water (Laurent a Gerhardt, *A Ch* [3] 24, 321, *A* 68, 365)— $(HA)_2 \cdot HCl$ laminae (Schwanert)— $(HA)_2 \cdot H_2PtCl_6$ yellow crystalline pp— $HA \cdot HNO_2$ colourless needles, v e sol water— CuA_2 pale blue scales S 033 in the cold, 07 at 100° (Hoffmeister)— $HgA_2 \cdot aq$ laminae Mercurio nitrate gives a white flocculent pp in a solution of leucine (R Hoffmann, *A* 87, 183)— $PbA_2 \cdot aq$ ppd by adding NH_3 aq to an aqueous solution of leucine and lead acetate (Strecker, *A* 72, 89)

Benzoyl derivative $C_6H_5 \cdot BzNO_2$ i.e. $C_6H_5(NHBz)CO \cdot H$ From leucine and $BzCl$ at 100° (Destrem, *Bl* [2] 30, 481) Granules, sol alcohol and ether In the preparation of leucine anhydride there is also formed the anhydride ($C_6H_5(NHBz)CO$)₂O, which is an amorphous body [85°] insol water and ether, v e sol alcohol Decomposed by boiling water into benzoic acid and the anhydride of leucine

Phthaloxyl derivative $C_6H_5(CO \cdot H)NH \cdot CO \cdot C_6H_5$ [132°] From leucine, alcoholic KOH , and phthalyl chloride (Reese, *B* 21, 277)— K_2A'' concentric groups of small slender needles

Anhydride (C_6H_5NO)₂O When the product of the action of $BzCl$ on leucine at 100° is treated with alcohol leucine anhydride remains undissolved, while its di benzoyl derivative (v supra) passes into solution (Destrem, *C R* 86, 484) Leucine anhydride is a white amorphous body, insol alcohol, but becoming gelatinous when boiled therewith It is not easily converted into leucine by boiling water

LEUCINDIN SULPHONIC ACID v INDIN

LEUCINIMIDE $C_6H_{11}NO$ Obtained in small quantity, together with leucine and tyrosine, by boiling proteids with dilute H_2SO_4 (Limpricht a Hesse, *A* 116, 201, Erlenmeyer, *A* 119, 17, Thudichum, *C J* 23, 409) Formed also when proteids are treated with bromine water (Hlasiwetz a Hebermann, *A* 159, 328), and, together with benzoyl-leucine, by heating leucine with $HOBr$ at 200° (Destrem, *Bl* [2] 30, 481). Mi-

amorphous, sl sol water— $\text{Ba}_2(\text{C}_2\text{H}_3\text{O}_2)_2$, flocculent pp— $\text{Pb}_2(\text{C}_2\text{H}_3\text{O}_2)_2$, pp— $\text{Ag}_2\text{C}_2\text{H}_3\text{O}_2$ (W)

Penta oxim $\text{C}_5(\text{NOH})_5$, Yellow crystalline solid Formed by the action of hydroxylamine upon croconic or leuconic acid. Decomposes suddenly at 172° — $\text{C}_5\text{H}_4\text{N}_5\text{O}_5\text{K}_2$, very explosive The penta oxim can be reduced by

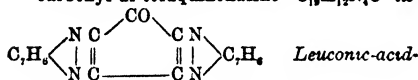

SnCl_2 to $\text{CH}(\text{NH}_2)$ $\begin{matrix} \text{C}(\text{NH}_2) & \text{C}(\text{NH}_2) \\ | & | \\ \text{C}(\text{NH}_2) & \text{C}(\text{NH}_2) \end{matrix}$ which forms crystalline salts

Tetra acetyl derivative of the penta-oxim $\text{C}_5(\text{NOH})(\text{NOAc})_4$, sq (from benzene) From the penta oxim and Ac_2O at 45° (Nietzki a Rosemann, *B* 22, 916) Plates (from Ac_2O) or needles containing chloroform (from chloroform) Sl sol hot benzene Decomposed at 100°

Tetra-oxim $\text{C}_4\text{H}_4\text{N}_4\text{O}_4$, s

$\text{CO} \begin{matrix} \text{C}(\text{NOH}) & \text{C}(\text{NOH}) \\ | & | \\ \text{C}(\text{NOH}) & \text{C}(\text{NOH}) \end{matrix}$ When potassium croconate (30 g) is gradually added to a cooled mixture of HNO_3 (45 g of S G 1.39) and water (40 g), and the product is diluted with water (500 cc) and heated with hydroxylamine hydrochloride (180 g) for some hours at 45° and finally at 100° there is formed a pp of mixed oxims This is dissolved in aqueous Na_2CO_3 and CO is passed in, whereupon the penta oxim is ppd while the tetra oxim can be ppd from the filtrate by HCl Yellow pp Explodes at 160° Its sodium derivative is v sol water, but is ppd on adding alcohol or NaCl , apparently in the form of $\text{Na}_2\text{C}_4\text{H}_4\text{N}_4\text{O}_4$

Carbonyl-di-toluquinoxaline $\text{C}_{18}\text{H}_{12}\text{N}_4\text{O}$ s

di tolylene-o diamide [above 300°] Formed by adding a salt of tolylene-o diamine to a cold aqueous solution of leuconic acid Golden yellow needles V sol warm chloroform, sl sol hot alcohol and acetic acid, insol water Weak base

Phenyl hydrazide $(\text{C}_6\text{H}_5\text{N})_2\text{C}_2\text{C}_6\text{H}_5\text{HPh}$ Red needles (from acetic acid), v sol chloroform, sl sol alcohol Weak base The hydrochloride forms a dark-green pp (Nietzki a Ben kiser, *B* 19, 776)

LEUCOTIN v COTO BARR

LEUCOTURIC ACID $\text{C}_8\text{H}_8\text{N}_2\text{O}_6$ Oxalantin

Formed when a solution of alloxanic acid is rapidly boiled down to a syrup, cold water is then added which leaves the leucoturic acid undissolved (Schlieper, *A* 56, 1) Formed also by reducing parabanic acid with zinc and HClAq in the cold (Limpricht, *A* 111, 134) White crystalline powder, insol cold, m sol hot, water Decomposes alkaline carbonates on boiling Decomposed by heating with KOH , giving off NH_3 , and forming oxaluric acid Its ammoniacal solution is ppd by AgNO_3 , and on boiling reduction takes place Boiling conc HNO_3 does not attack it

LEVONIC ACID $\text{C}_8\text{H}_8\text{O}_8$ 3aq An acid said by Wiederhold (*C* 1884, 971) to be obtained by boiling levulose with baryta water Yellowish brown powder, v sol alcohol and water Decomposed by heat.

LICARENE $\text{C}_{10}\text{H}_{16}$ (168° – 172°) S G 1.835 An inactive terpene obtained by the action of ZnCl_2 or P_2O_5 on the essential oil of *Lucaria Kanak* (Morin, *A Ch* [5] 25, 427) Conc HClAq forms $\text{C}_{10}\text{H}_{16}\cdot 2\text{HCl}$, a colourless liquid, S G 1.1069, inactive to light, and decomposed on distillation into hcareene and hydrochloric acid The essential oil $\text{C}_{10}\text{H}_{16}\text{O}$ might be looked upon as hcareene hydrate and exhibits the following properties—(198°) at 755 mm S G 1.568, $[\alpha]_D = -19$ at 15° It is sol alcohol, ether, and glycerin

LICHENINE $\text{C}_8\text{H}_{10}\text{O}$, Occurs in Iceland moss

Preparation—*Cetraria islandica* or other similar lichen is heated for several hours with a 2 p c solution of K_2CO_3 The aqueous solution is ppd by alcohol (Honig a Schubert, *M* 8, 460, cf Knop a Schnedermann, *A* 55, 164, Maschke, *J pr* 61, 7, Davidson, *N Ed P J* 28, 260, Errera, *Bn* 1, 882, Bauer, *J pr* [2] 34, 49, Klason, *B* 19, 2541)

Properties—Gelatinous pp, v sl sol cold water Boiling water forms an opalescent solution, reppd on cooling or on adding alcohol Gives no blue colour with I and H_2O_2 Dissolves in HCl , from which solution it is ppd in snow-white flocks by alcohol Weak hot acids convert it after some time into a dextro rotatory sugar $[\alpha]_D = +55^\circ$ Glucose is also formed Two carbohydrates, resembling soluble starch in their properties, are present in the aqueous solution

LICHENO-STEARIC ACID $\text{C}_{18}\text{H}_{34}\text{O}_2$ [c 120°] An acid occurring in Iceland moss (Schnedermann a Knop, *A* 55, 149), and probably also in the fly agaric or toadstool (Bolley, *A* 86, 50) Obtained by boiling Iceland moss for 15 minutes with dilute alcohol and some K CO_3 , filtering, adding HClAq and 4 volumes of water The pp is boiled with alcohol of 45 p c, whence a mixture of lichenostearic and cetraric acids separates on cooling The lichenostearic acid is extracted from the mass by petroleum and recrystallised from alcohol Mass of radiating needles which soon change to delicate pearly laminae Has a rancid taste Insol water, v sol alcohol, ether, and oils Is not attacked by AcCl On oxidation it yields CO_2 and decolic acid (Hilger a Buchner, *B* 23, 461) The ammonium salt forms a jelly containing extremely slender needles— BaA' , greivish white pp which cakes together in boiling water— PbA' , flocculent pp fusing under water— AgA'

LIEBERMANN'S REACTION A blue or green colour obtained by warming phenol with H_2SO_4 containing nitrous acid It may be used as a test for phenol or for nitrous acid Various derivatives of phenol may be used instead of phenol, while nitroso and oximido compounds usually react like nitrous acid

Chloride C₂H₅COCl [48°–50°] Plates
Sol ether

LIGNONE (*Lignum, Lignose, Lignification*)
Lignification, or the process of wood formation, is one of the principal of the modifications of the cell-wall, by which it and the tissues containing it are differentiated for fulfilling their several functions. The history of a lignified cell, or rather of the substance of the cell wall, is usually stated to consist of (1) the elaboration of the primary cell wall from materials in protoplasm, and formed at its limiting film as an envelope of pure cellulose, (2) the induration of this cell-wall, *ie* lignification, by the infiltration of substances, which when deposited are known as 'lignin,' or more vaguely as 'incrustative' substance. Lignification is recognised by the morphological changes with which it is associated, as well as by the very characteristic reactions of the product (Goodale, *Phys Botany*, 1885). These products, although presenting a wide range of differences, corresponding with variations in structural and other characteristics of the tissues which they compose, fall naturally, and as regards their chief constituent, into a homogeneous chemical group, designated by the term lignocellulose, of which the typical features are represented in the substance of the jute fibre (vol 1 p 719).

It is the purpose of this article to give a brief account of more recent researches into the constitution of this typical lignocellulose, and to show the bearings of the results arrived at upon the chemistry of the woods, the most numerous and important section of the group. The advantages of the jute fibre over the latter as a subject of study are that it is a simple tissue, whereas the woods are complex aggregates, that as an isolated fibred it is much more easy of penetration by reagents, and that as a product of only a few months' growth it has not undergone such secondary changes in composition as necessarily take place in the substance of a perennial stem or true wood. Such characteristics mark out the jute fibre substance as a natural basis for the general solution of the chemical problem of lignification.

Evidence has already been given (vol 1 *loc cit*) for regarding this product as chemically homogeneous, which view is further developed in the investigations referred to (*C J* 1889 199). In all reactions in which hydroxyl groups only are brought into play—hydrolysis and etherification—it behaves as an integral compound (lignocellulose), of which the formula C₁₂H₁₀O₅ is an approximate empirical expression. The limit of 'nitration' is the tetranitrate, indicating a number of OH groups in the original less by two than in the molecule of cellulose, similarly represented, *ie* as C₁₂H₂₀O₁₀. The product is of a bright gold colour, with a silky lustre. In further contradistinction to

cellulose, the OH groups of the lignocellulose react with acetic anhydride at its boiling point. Its reaction with chlorine has been studied quantitatively, 1 gm of the purified fibre substance takes up 54–55 c c Cl (calc at 0° and 760 mm), or approximately 16 p c by weight the quantity of Cl as HCl formed being equal to that entering the molecule. The chlorinated product *n*(C₁₂H₁₀Cl₂O₅),¹ a simple substitution-derivative of the non-cellulose constituent (which we may regard as *n*(C₁₀H₈Cl₂O₄)), contains mairgallol in combination with a body not yet completely studied, but yielding furfural on hydrolysis. In addition to the molecular groupings thus indicated, the presence of methyl groups is proved by the formation of methyl chloride on heating this compound, and of acetic acid on destructive distillation of the fibre substance, as also by dissolving it in sulphuric acid, diluting and distilling. These results afford a general view of the constitution of the 'lignin' substance, as it has been termed hitherto. We may regard it as containing closed C₆ chains, further characterised by the presence of ketone or quinone oxygen, and united to the furfural yielding body, which is probably related to 'wood gum' ('Holzgummi'). Tollens has, in fact, isolated xylose from the jute fibre (*B* 22, 1046), though in very small quantity, and we would note here the increase in the proportion of the parent substance, wood-gum, with the more advanced lignification of perennial stems, as additional evidence for this view. It is difficult to localise the methyl groups, but they would appear to be independent of the above, and may be regarded as existing in an acetic residue in combination. For a substance of marked ketonic and aldehydic characteristics, the terms *lignum* and *lignose* are obviously unsuited, and should give place, according to present views, to *lignone*, by which, therefore, we shall designate the non cellulose component of the lignocelluloses generally.

The lignone of plant cells generally in the earlier stage of growth, *ie* lignification, appears to be not merely similar to but identical with that of jute. Proof of this has been afforded by the particular investigation of such widely differing structures as the stony concretions of pears—Erdmann's glycydrupose—the fibrovascular bundles of *Musa Paradisiaca* (Monocot), and the bast fibres of the *Sida* species (*C J* 1882, 108, 1883, 19, 1889, 212).

But very few of the woods have been particularly investigated in regard to the constitution of the wood substance, and for the most part only in regard to the products of hydrolysis (v vol 1 p 719). Thus Erdmann concluded from his study of coniferous wood that its chief constituent—'glycolignose'—is a chemical individual C₃₀H₄₄O₂₁, a species of glucoside resolved by treatment with boiling acids into 'lignose' C₁₈H₂₆O₁₁ and a fermentable sugar (glucose). The presence of closed C₆ chains in the 'lignose' molecule was evidenced by its yielding protocatechuic acid on fusion with alkaline hy-

¹ A more direct conversion of the lignone into definitely aromatic products is that which takes place spontaneously when masses of jute are exposed to moisture and heat. From specimens of fibre 'rotted' under such conditions Cross and Bevan obtained an astringent substance C₁₀H₆O₄, which yielded phloroglucinol and protocatechuic acid on fusion with potash (*C J* 1882, 93).

drates It was also concluded that the wood of the widely different poplar species was similar if not identical in composition (*A Suppl* 5, 228)

The later researches of F Bente (*D P J* 217, 235), although modifying these views, chiefly in the variation in the results of hydrolysis, nevertheless in the main confirm them. The general conformity of the woods to the types above described as representative is shown

(1) In the close similarity of their characteristic reactions. Of these we may mention (a) the colouration produced with solutions of the aromatic amines (golden yellow), and of solutions of the phenols in hydrochloric acid, most characteristic of which is the reaction with phloroglucin (crimson), (b) the powerfully reducing action of the wood substance upon the oxides of copper, silver, gold, and mercury—showing the presence of aldehydic groups, (c) the reactions with the halogens yielding, in the case of chlorine, substitution products of definite quinone chloride characteristics, attended by complete resolution into lignone (chloride) and cellulose with bromine and iodine less definite compounds, but constant under constant conditions, (d) with nitric and sulphuric acids yellow-coloured explosive nitrates, (e) with acetic anhydride at its boiling point and with benzoyl chloride in presence of alkalis, the corresponding ethereal derivatives, (f) with solutions of the caustic alkalis at 160°–190°, with bisulphites (of the alkaline earths) at 150°–170° and with sulphurous acid (7 p.c. solution) at 90°–105°, attended by complete resolution into lignone (soluble derivatives) and cellulose (insoluble)

(2) In their empirical composition, which shows a remarkable uniformity throughout the group. This is illustrated in the appended table of results of analyses and determinations of calorific equivalents (Gottlieb, *J pr* 2] 28, 385) —

Wood	Ash	Nitrogen	Carbon	Hydrogen	Calorific equivalents per 1 gram
Oak	0.37	—	50.16	6.03	4620
Ash	0.57	—	49.18	6.17	4711
Hornbeam	0.50	—	48.99	6.20	4728
Beech	0.57	0.09	49.06	6.11	4777
Birch	0.29	0.10	48.88	6.06	4771
Fir	0.28	0.05	50.36	5.92	5035
Pine	0.37	0.04	50.31	6.20	5085

An investigation by N Schuppe of the chemical composition of a number of woody tissues (*Pharm J* [3] 14, 52) led to the following conclusions (a) that the woods are uniform in their characteristics, being composed of cellulose and 'lignin' in somewhat variable proportions, (b) the cellulose when isolated (Schultze's process) having the composition $C_6H_{10}O_5$, and (c) 'lignin,' being represented by the empirical formula $C_{11}H_{18}O_6$, which is closely similar to that obtained for the 'lignone' of jute. Further, G W Hawes has examined the woods of typical acrogens, e.g. lycopodium, equisetum, and aspidium, and finds that they do not differ essentially in composition from exogenous woods (*Am S* [3] 7, 585)

Vol. III.

(3) In the products of their destructive distillation, which, when carried out under uniform conditions, gives results which are very similar for the several woods. A very elaborate series of such distillations was carried out by M Senff (*B* 18, 60), the results being given in percentages of the wood under (1) total distillate, (2) tar, (3) crude vinegar, (4) anhydrous acid (acetic), (5) charcoal, (6) gases. The following numbers represent the limits of the percentages observed: (1) 40–50, (2) 3–8, (4) 2–6, (5) 20–30, (6) 17–35. The woods of all the more important species, e.g. Quercus, Populus, Betula, Fagus, and Pinus, were included in the research, and shown by the results to resemble one another very closely in composition. The products may be more particularly classified as regards the light which they throw upon the molecular grouping of the parent substance into (a) members of the fatty series alcohols, ketones, aldehydes, and acids generally of low molecular weights, (b) furfural and its homologues, (c) a group of aromatic bodies, constituting 'creosote,' which may be described as a mixture of guaiacol and creosol, containing besides, methyl creosol and the dimethyl ethers of pyrogallol and its homologues in varying proportions (Schorlemmer, 'History of Creosote,' *S C I* 4, 152). These divisions, it will be noted, correspond with the ascertained grouping of the complicated lignone molecule (*supra*), of which they afford additional confirmation. It is obvious that the process of destructive distillation must be attended with complications arising from secondary reactions, but the temperatures in the case of wood are sufficiently low to reduce these to a minimum, thus the yields of furfural are at a maximum when the temperature does not exceed 200° (Heil, *B* 10, 936), and the acetic acid is increased considerably beyond the percentages given by Senff (*supra*), viz. from 2–6 to 5–10, by raising the temperature very gradually through 150°–300° (W Rudnew, *D P J* 264, 88 & 128), no doubt at the expense of the methylation of the aromatic derivatives. This subject, however, except in regard to the outlines which we have sketched, belongs rather to the general theory of destructive distillation.

The fundamental tissue of the woods we regard, therefore, in all cases as a lignocellulose, of which the lignone portion, while possessing the typical characteristics common to the group, is no doubt variously differentiated with the specialised characteristics of families, and indeed species and individuals.

In addition to the fundamental tissue the woods contain other constituents, which from their nature are seen to be more or less adventitious. They are, in fact, generally removable by the action of solvents (in the case of resins, gum resins, balsams, &c.), or by simple hydrolysis. In this group we may mention such definitely aromatic derivatives as coniferin and vanillin (M Singer, *M* 3, 395), the tinctorial constituents of the dye woods, also the very characteristic and important constituent of most exogenous woods known as 'wood-gum' (Holzgummi), first described by Thomsen (*J pr* [2] 19, 146), who found quantities varying from 8 p.c. to 20 p.c. of the woods examined. This body yields on hydrolysis the C₆ sugar, xylose (Tollens, *Unters a d Agr Chem Lab Göttingen An-*

L

malen, 254, 325), which by further resolution yields furfural. Whether the wood gum is a product of resolution of the lignone molecule has not yet been disclosed, but it would appear to be probable. A similar remark applies to the aromatic derivatives above mentioned.

In conclusion we must briefly notice a recent contribution to the subject of the 'constitution of lignin' (Lange, *Ztschr Physiol Chem* 14, 217). This consists in a study of the soluble products of resolution of certain woods—beech, oak, and fir—by heating with strong solutions of the alkaline hydrates at 185°. In addition to formic and acetic acids, traces of higher fatty acids, oxalic acid and small quantities of pyrocatechol and protocatechuic acids, there were obtained certain amorphous bodies of brown colour, which the author terms lignic acids. These were resolved by treatment with alcohol into (a) soluble, (b) insoluble in this menstruum. The empirical composition of these derivatives is subjoined

	(a)	(b)
Lignic acids	Beech C 61.3 H 5.4 Oak C 60.9 H 5.4 Fir C 61.5 H 5.0	C 59.0 H 5.4 — C 60.4 H 5.0

The yield of these bodies is from 12 to 15 p.c. of the weight of the wood. The insoluble residues from the original alkaline digestion are described as 'celluloses,' but the description is doubtful. These results have an empirical value, but throw little light on the constitution of the wood substance. They afford additional evidence, however, of the general similarity of woods of various origin.

Digested with alkalis at higher temperatures (200°–250°) than those employed in the researches detailed above, the lignocelluloses are resolved for the most part into oxalic and carbonic acids. With potassium hydrate—which appears to give the maximum yield—the following proportions of oxalic acid have been obtained, the yield being calculated on the dry woods: pine, 94.7 p.c.; poplar, 93.2 p.c.; oak, 83.4 p.c. (W Thorne, *D P J* 210, 24). It is evident that the oxalic acid is derived from both lignone and cellulose, which are therefore probably similarly constituted as regards the arrangement of the C atoms.

The action of the alkalis, however, at the point at which they resolve the lignocellulose is too severe to afford any trustworthy evidence, from the study of the products, as to the constitution of the original substance. The problem can only be solved by first studying those reactions which yield definite substitution or other real derivatives; these are chiefly chlorination, conversion into nitrates, acetates, and benzoates, and the reaction with bisulphites (solutions) at high temperatures.

In this article we do not attempt a special description of the woods or their constituents, our endeavour is rather to generalise what is known concerning the wood substance proper, that which resists mechanical solvents altogether, and hydrolytic agents up to a certain degree of intensity. C F C

LIGRON The mixture of homologues of methane obtained by collecting the portion of petroleum that boils below 100°.

LIGULIN A crimson colouring matter in ripe privet berries (Nicklés, *J Ph* [3] 35, 328),

sol water and alcohol, insol ether. Does not contain nitrogen. Coloured green by alkalis.

LIGUSTRIN A yellow hygroscopic bitter mass extracted from leaves of the privet (*Ligustrum vulgare*), insol ether and alcohol, sol water and dilute alcohol. Conc. H_2SO_4 gives an indigo blue solution (Polex, *Ar Ph* [2] 17, 75).

LIGUSTRON [c 100°] (260°–280°). Occurs in privet bark (Reinsch, *J* 1847, 787). Needles, v sol water, alcohol, and ether. Tastes bitter. Reduces ammoniacal AgNO_3 .

LIME Oxide of calcium, CaO , v vol 1 p 368.

LIME, CHLORIDE OF A name sometimes given to *bleaching powder*, v BLEACHING POWDER, vol 11 p 17.

LIME LEAF OIL The fragrant oil obtained by distilling the leaves of *Citrus Limetta* with steam contains a citrene (c 176°), 1 active to light, and with refractive index for red rays 1.4611 at 30°, terpinol, methyl ennyl ketone, and a colophene (F Watts, *C J* 49, 316).

LIMES, OTTO OF Obtained by rasping and squeezing from the unripe peel of the fruit of *Citrus limetta*. Contains a terpene (176°) and a soft resin, not volatile at 250°. On standing the resin deposits $\text{C}_{10}\text{H}_{16}\text{O}$, [102°] (Wright a Piesse, *C J* 32, 548).

LIMETIC ACID $\text{C}_8\text{H}_8\text{O}_4$. Obtained by the action of H_2SO_4 and $\text{K}_2\text{Cr}_2\text{O}_7$ on the oil of lime (from *Citrus Limetta*) and on oil of rosemary (Vohl, *N Ber Arch* 74, 16). White crystalline body, may be sublimed. Has no taste or smell. Sol water, v sol alcohol—Ag. A powder, sl sol water, blackening on exposure to light.

LIMETTIN $\text{C}_8\text{H}_8\text{O}_4$, [122°]. A neutral body occurring in oil of limes (Tilden, *C J Proc* 6, 30). Tufts of pale yellow needles (from alcohol). Not acted upon by AcCl or by phenylhydrazine. Bromine forms colourless scales of $\text{C}_{10}\text{H}_{11}\text{Br}_2\text{O}_6$. Boiling conc. NaOH forms NaOAc and crystalline $\text{C}_8\text{H}_{11}(\text{OH})\text{O}$.

LIMONENE A terpene occurring in oil of lemon and in many other essential oils, v TERPENE.

LIMONIN $\text{C}_{15}\text{H}_{24}\text{O}$, [275°] (Paterno a Ogialoro, *G* 9, 64), [245°] (Hoffmann *Ar Ph* [3] 14, 839). A bitter substance contained in the pips of oranges and lemons (Bernays, *Buchner's Rep* [3] 21, 306, *A* 40, 317, Schmidt, *A* 51, 338). The pips are exhausted with boiling water, alcohol is added, and the mixture is boiled with inverted condenser. After filtering, and distilling off the alcohol, limonin is left, together with a fatty substance which may be removed by CS_2 . 1500 g of pips yield 80 g of limonin (P a G). Laminæ, sl sol water, ether, and NH_4Aq , v sol alcohol, HOAc , KOH aq, and baryta water. The barium salt is not decomposed by CO . Conc. H_2SO_4 forms a red liquid, from which the limonin is ppd by water.

LINALOES OIL The essence of linaloes, obtained from the wood of *Lycari kanali*, the white cedar of Cayenne, is a slightly coloured liquid with an odour like rose and lemon. After distillation over CaCl_2 it consists of $\text{C}_{10}\text{H}_{16}\text{O}$ (198°) SG 1.868 [α_D^{20}] = -19 at 15°. It is sol alcohol, ether, and glycerin. When distilled with ZnCl_2 it yields a terpene, v LIGARENE. By prolonged treatment with saturated HCl aq and

exposure to light it yields $C_{18}H_{35}BrO_2$, an optically inactive liquid with a camphor like odour, and SG 1.069 When distilled with lime it yields leucarene $C_{18}H_{36}$ (ca 170°), SG 1.835 (Morin, *C R* 92, 998, 94, 733)

LININ $C 62.9 p c H 47 p c$ AcrySTALLISABLE substance obtained by digesting *Linum catharticum* with milk of lime, filtering, ppg with HCl, and extracting with ether. (Pagenstecher, *A* 40, 322, C Schröder, *N Rep Pharm* 10, 11) Silky crystals, v sl sol water, v e sol alcohol and ether, m sol chloroform and HOAc The alcoholic solution is intensely bitter

LINOLEIC ACID $C_{18}H_{32}O_2$ *Linolic acid* SG 1.492 Occurs as glyceryl ether in linseed oil, hemp oil, poppy oil, olive oil, nut oil, cotton seed oil, earth nut oil, almond oil, oil of sesame, palm oil, cacao butter, and probably in most fixed vegetable oils (Pelouze & Boudet, *A Ch* [2] 59, 43, Laurent, *A Ch* [2] 65, 150, 298, Liebig, *A* 33, 113, Sacc, *A* 51, 214, Schuler, *A* 101, 252, Oudemans, *J* 1858, 304, Hazura & Grussner, *M* 9, 944, 10, 242, Benedikt & Hazura, *M* 10, 353) It does not occur in animal oils, so that when the acids obtained by saponifying animal oils are oxidised by $KMnO_4$, no sativic acid will be formed, but di oxy stearic acid will be among the products, this being derived from oleic acid (B & H)

Preparation—Crude linseed oil or hemp oil is evaporated with aqueous NaOH, the sodium soap is decomposed by H_2SO_4 , and the crude acid dissolved in alcohol, neutralised with NH_3 , and ppd by $BaCl_2$. The barium salt is dissolved in ether, HCl is added, the ether decanted from ppd $BaCl_2$, evaporated, and the liberated acid dried *in vacuo* over H_2SO_4 (Schuler, Bauer & Hazura, *M* 7, 216) The acid so obtained is a mixture of oleic, linoleic, linolenic, and iso linolenic acid (Hazura) By treatment with bromine at 0° and reduction of the product $C_{18}H_{32}Br_2O_2$ with zinc and HCl pure linoleic acid is got

Properties—Faintly-yellow lumpid oil Does not solidify at -18° Insol water, v sol ether, m sol alcohol When distilled under 90 mm pressure one third passes over at 290° , and the distillate contains sebacio acid $C_{16}H_{30}O_2$ [130°] and an oily mixture (Hazura & Grussner, *M* 9, 206, cf Norton & Richardson, *B* 20, 2735)

Reactions—1 Potash fusion gives myristic, acetic, and formic acids, with traces of azelaic acid—2 $KMnO_4$, hydrogen peroxide, and MnO_2 with H_2SO_4 oxidise it to azelaic acid—3 $KMnO_4$ in presence of KOHAq converts it into sativic acid, some azelaic acid also being formed But alkaline $KMnO_4$ oxidises crude linoleic acid from linseed oil (100 g) into sativic acid $C_{18}H_{32}(OH)_2O_2$ [173°] (6.5 g), linusic acid $C_{18}H_{30}(OH)_2O_2$ [204°] (4.5 g), isolinusic acid [175°] (15.8 g), and di oxy stearic acid $C_{18}H_{34}(OH)_2O_2$ [137°] (1.2 g) (Hazura, *M* 9, 180 cf Dieff & Reformatsky, *B* 20, 1211) It appears therefore that crude linoleic acid consists of linoleic acid $C_{18}H_{32}O_2$ (which gives sativic acid on oxidation), linolenic acid $C_{18}H_{30}O_2$ (which gives linusic acid), isolinolenic acid (which gives isolinusic), and oleic acid (which gives di oxy stearic acid) The formation of sativic acid in this manner may be made use of as a test for linoleic acid—4 Bromine at ordinary temperatures forms with crude linoleic

acid solid $C_{18}H_{30}Br_2O_2$ [177°] Bromine at 0° forms a tetrabromide $C_{18}H_{26}Br_4O_2$ [115°] (Hazura, *M* 8, 147, Hazura & Friedrich, *M* 8, 155, 265) Of these two compounds the former is formed from linolenic, the latter from linoleic acid Pure linoleic acid gives only $C_{18}H_{32}Br_2O_2$ [115°]—5 Fuming HIAq and amorphous phosphorus converts it into stearic acid (Peters, *M* 7, 552)

Salts—The salts are not crystalline With the exception of the salts of the alkalis they are insol water They are sol ether With the exception of the Pb, Mn, Na, and NH_4 salts they are insol alcohol— BaA' (Peters)

Linolenic acid $C_{18}H_{30}O_2$ Obtained by treating the compound $C_{18}H_{32}Br_2O_2$ [177°] (*v supra*) dissolved in alcohol with zinc and HCl (Hazura, *M* 8, 267) Yields on oxidation by alkaline $KMnO_4$ no solid acid except linusic (hexa oxy stearic) acid [201°] Bromine forms only $C_{18}H_{30}Br_2O_2$ [177°] Linolenic acid 'dries' rapidly when exposed to air, through oxidation Its salts behave in like manner The more glyceryl linolenate there is in an oil the more rapidly does it dry Glyceryl linolenate and isolinolenate also possess drying properties, but glyceryl oleate does not The product produced by exposing the acids to air is an anhydride, insol ether, but furnishing soluble acids when heated with alkalis

Isolinolenic acid $C_{18}H_{30}O_2$ An acid assumed to exist in crude linoleic acid on account of the formation of isolinusic acid on its oxidation When crude linoleic acid is oxidised by $KMnO_4$ in alkaline solution, and the product ppd by H_2SO_4 , there is obtained a mixture of fatty acids whence cold ether extracts di oxy stearic acid, sativic acid remaining undissolved The filtrate from the ppd acids is neutralised with NaOH, evaporated, again ppd with H_2SO_4 , the pp extracted with ether, and the residue crystallised from alcohol and then from water, whereby it may be separated into linusic and isolinusic acids

LINSEED OIL The oil expressed from the seeds of flax (*Linum usitatissimum*) Like other drying oils when exposed to the air it dries up to a transparent resinous mass Linseed oil is composed of the glyceryl ethers of oleic, linoleic, linolenic, and isolinolenic acids **LINOLEIC ACID** Linseed oil dissolves some oxide of lead when heated therewith, being decolourised and rendered more easily drying (boiled oil)

LINUSIC ACID *v* HEXA OXY STEARIC ACID

Isolinusic acid *v* HEXA OXY STEARIC ACID

LIQUIDAMBAR A balsam obtained from a large tree, *Liquidambar styraciflua*, growing in Florida and Mexico It resembles balsam of Peru, containing cinnamyl cinnamate, styrene, and cinnamic acid (Harrison, *Ar Ph* [3] 6, 541, Maisch, *Ar. Ph* [3] 6, 545)

LIQUIDS, diffusion, dispersion, osmose, refraction, transpiration, of, *v* PHYSICAL METHODS

LITHIUM Li At w 7.01 Mol w probably 7.01 (*v p* 149) [180°] (Bunsen, *J* 8, 324) SG 578 to 589 (Bunsen, *l c*) SH 27° to $100^\circ = 9408$ (Regnault, *A Ch* [3] 68, 11) EC at 20° (Hg at $0^\circ = 1$) 10.69 (Mathiessen *P M* [4] 12, 199, 13, 81) Characteristic lines in emission spectrum are L_{α} in the red 6705.2, and a

weaker line in the orange $\delta 102$, and a weak line in the blue 4602.7 (Thalen, 1868, v also L de Boisbaudran, *Spectres Lumineux*, p 55, Schön, W 10, 143, Liveing & Dewar, T 1883 187) S V S 119

Occurrence—Salts of Li are very widely distributed, but occur only in small quantities. Several phosphates of Fe and Al contain Li phosphate, especially *traphylina*, which contains c 7 p c Li_2O , many silicates of Al and Fe contain small quantities of Li silicate, especially *lepidolite*, which sometimes contains from 3 to 5 p c Li_2O . Tourmalines, borates, &c, often contain traces of lithia. Very many mineral springs contain lithia, according to Kirchhoff a Bunsen lithia is present in almost all mineral waters (P 113, 357). Truchot found lithia in the soil of L'imague in the Auvergne, nearly all the plants growing on this soil take up lithia (C R 78, 1022). Dieulaufait has found traces of Li in sea water from all parts of the globe, in the water of marshes, in mineral springs, in primary rocks, in gypsum of different formations (A Ch [5] 17, 377). Lithia is found in many plants, and in all sorts of tobacco, but not in raw sugar, cocoa, coffee, or tea (Focke, *Der Naturforscher*, 1872 307, Grandeau, A Ch [3] 67, 216). Lithia has also been found in the milk and blood of cows (Bunsen & Kirchhoff), in different parts of the human organism (Bence Jones, P M [4] 29, 394), and in normal urine (Schiaparelli & Peroni, G 10, 390).

While investigating various silicates in 1817, Arfvedson (S 22, 93, 34, 214) found a new alkali base with a molecular weight smaller than that of soda or potash. Berzelius gave the name *lithia* to the new base (*lithios*) supposing that, unlike soda and potash, it was to be found only in minerals. The new alkali was decomposed by electrolysis in 1818 by Davy, also in 1820 by Brandes (S 8, 120), but the metal was first prepared approximately pure and in considerable quantity by Bunsen and Matthiessen in 1855 by electrolyzing fused LiCl (A 94, 107).

Preparation—The metal is obtained by electrolyzing molten LiCl . Bunsen & Matthiessen (A 94, 107) passed the current from 4-6 Bunsen cells through LiCl kept molten in a thick walled porcelain crucible, using a cylindrical rod of rector graphite as positive electrode, and an iron wire the thickness of an ordinary knitting needle as negative electrode. The metal separated on the iron wire in small pellets, which were quickly removed by an iron spoon and placed under petroleum. Some of the metal was always oxidised, occasionally with ignition. To obviate this, Hiller (*Neues Handwörterbuch der Chemie*, 8, 534) passed the negative electrode (iron wire) through the stem of a tobacco pipe, which he connected with an apparatus supplying pure dry H_2 , he allowed H_2 to pass through the pipe until air was completely expelled, then plunged the bowl open end downwards, with the end of the wire inside, into the molten LiCl , stopped the H_2 , and sent the current through the LiCl , when sufficient Li had collected inside the bowl, the pipe was broken and the metal collected under petroleum. To prevent any action between the Li and the silica in the pipe, the inside of the bowl is covered with a thin layer of graphite, this is done by mixing powdered graphite with

dilute LiCl aq so as to form a thick paste, spreading this inside the bowl, and drying first in air and then at a moderate red heat. It is advantageous to mix the LiCl before fusion with some NH_4Cl .

There are many methods for preparing LiCl from Li containing minerals, the methods vary according to the composition of the mineral dealt with, all seek to prepare a solution containing only the alkalis, from which Li may be separated by taking advantage of the comparatively small solubility in water of Li_2CO_3 . LiCl is obtained by dissolving Li_2CO_3 in HCl aq, evaporating, and drying the crystals which separate. *Lepidolite* is the usual starting point, different specimens contain from less than 1 to c 5 p c Li_2O . The mineral is very finely powdered and triturated with water, the finest powder is dried and heated to redness with twice its weight of lime, the cold mass, in which the SiO_2 is combined with lime, is treated with HCl aq, CaO is added from the solution by H_2SO_4 aq and evaporation, the filtrate is evaporated to dryness, and the solid is heated until H_2SO_4 is all removed, the residue is dissolved in water, the solution is digested with CaCO_3 to remove Al_2O_3 , and Ca is removed by pptn with $(\text{NH}_4)_2\text{C}_2\text{O}_4$, the filtrate is evaporated to dryness, and the residue is strongly heated, the Li_2SO_4 thus obtained is dissolved in water, and the liquid is added by Ba acetate, after filtration the Li acetate is strongly heated and so transformed into Li_2CO_3 (Arfvedson, S 22, 93, 34, 214).

The method recommended by Hauer (J pr 68, 310) consists in strongly heating for 2 hours a mixture of equal parts of very finely powdered *lepidolite* and gypsum, lixiviating the mass with water, filtering, evaporating until CaSO_4 and K_2SO_4 crystallise out, adding to the mother-liquor a mixture of NH_4Aq , NH_4HSAq , and $(\text{NH}_4)_2\text{C}_2\text{O}_4$ aq, whereby all bases are pptd except the alkalis, after filtering, Li_2CO_3 is pptd from the warm solution by $(\text{NH}_4)_2\text{CO}_3$.

The process adopted in Schering's manufactory at Berlin is described by Filsinger (D P J 219, 183, 222, 321, 385). Finely ground and sifted *lepidolite* is mixed with conc H_2SO_4 in a warm brick trough to the consistence of a thin paste, which is heated with slight stirring till it forms into lumps, the lumps are calcined in a reverberatory furnace, and, while warm, are lixiviated with water, the liquid is mixed with enough K_2SO_4 to convert all Al_2O_3 into alum, which separates on boiling, the residual Al_2O_3 being removed by milk of lime, the salts in the filtrate are converted into chlorides by pptn with BaCl_2 aq, and the liquid is evaporated to dryness, digestion with absolute alcohol dissolves the chlorides of Li and Ca , after distilling off alcohol, Ca is pptd by $(\text{NH}_4)_2\text{C}_2\text{O}_4$ aq, the liquid is filtered, and a little NH_4HSAq is added to ppt any Fe, &c, still present, the filtrate is boiled to remove NH_4HS and evaporated to dryness in a silver dish, pure LiCl is thus obtained. The LiCl may be converted into Li_2CO_3 by dissolving in water, adding NH_4Aq and $(\text{NH}_4)_2\text{CO}_3$, and washing the ppt with alcohol of 60 p c.

Schrötter's method is said to be one of the best (J pr 93, 275). *Lepidolite* is melted, at full red heat, with frequent stirring, the molten mass is ladled out by an iron spoon into water,

when cold the solid is powdered and triturated with water, HClAq S G 12 is added little by little to the pasty mass, care must be taken that sufficient water is present to prevent the whole mass from solidifying, after standing for 24 hours, with frequent stirring, the semi liquid substance is heated nearly to boiling, and a little more HClAq S G 12 is added, the total quantity of HCl used should be c 2 parts to 1 part lepidolite, after a few hours most of the SiO_2 has separated, a little of the filtered liquid should be so acid that no permanent pp is formed on addition of a few drops of $\text{Na}_2\text{CO}_3\text{Aq}$, a little HNO_3Aq is now added to completely oxidise FeCl_2 to FeCl_3 , the liquid is filtered from ppd SiO_2 (which separates as a powder), and Fe_2O_3 , Al_2O_3 , CaO , MgO , &c, are ppd by careful addition of $\text{Na}_2\text{CO}_3\text{Aq}$ to the boiling liquid. The alkaline filtrate is nearly free from all salts except chlorides of the alkalis, it is evaporated until the small quantities of MgCO_3 , MnCO_3 , &c, still present separate out, and Li_2CO_3 is ppd from the filtrate by addition of Na_2CO_3 and evaporation.

Commercial Li_2CO_3 generally contains small quantities of salts of Mg, Ca, K, Na, &c, it may be purified by one of the foregoing methods. For the other methods of preparing Li_2CO_3 from lepidolite, &c v Hugo Muller, *J pr* 58, 148, Fuchs, *J pr* 5, 319, Troost, *A Ch* [3] 51, 103, Mallet, *A* 101, 389, Lunglmayr, *D P J* 171, 293, Allen, *J pr* 87, 480, Reichardt, *D P J* 172, 447, L Smith, *A* 159, 82, Stolba, *D P J* 198, 225, L de Boisbaudran, *Bl* [2] 17, 551. A detailed criticism of various methods will be found in *D P J* 219, 183, 222, 271 385.

Properties — A silver white metal, very soft, but harder than K or Na, when freshly cut, the surface appears yellowish, when melted and at once pressed between glass plates it forms a silver like mirror. Li makes a grey streak on paper. It may be drawn into wire, but shows very little tenacity. Li is the lightest known solid, S G c 59, it swims on rock oil. Melts at 186° . Is not acted on by dry O at its M P, heated in air to c 200° it burns with a very brilliant white flame. May be vapourised in H at full red heat. Li decomposes cold water without itself melting, it combines rapidly with Cl, Br, I, S, O, it burns when heated in dry CO_2 . Li reacts with most acids to form salts, conc HNO_3Aq oxidises it with great rapidity, the metal usually melts, and is sometimes ignited. Li dissolves in liquid NH_3 , and on evaporation of the NH_3 it is left unchanged (Seeley, *C N* 23, 169).

The atomic weight of Li has been determined (1) By converting LiCl into AgCl (Arfvedson, *S* 22, 43, Mallet, *Am S* [2] 22, 349, Troost, *A Ch* [3] 51, 108, Stas, *Nouv R* 268), (2) by determining O in Li_2O (Berzelius, *P* 17, 379), (3) by ppg Li_2SO_4 by BaCl_2 (Berzelius, *P* 17, 379, Heumann, *P* 15, 482, Hagen, *P* 48, 361, Diehl, *A* 121, 97), (4) by determining CO_2 in Li_2CO_3 (Hermann, *P* 15, 480, Troost, *A Ch* [3] 51 108, Diehl, *A* 121, 93), (5) by converting Li_2CO_3 into Li_2SO_4 (Troost, *A Ch* [3] 51, 108), (6) by converting LiCl into LiNO_3 (Stas, *Nouv R* 274), (7) by determining SH of Li (Regnault, *A Ch* [3] 68, 11).

Ramsay (*O J* 55, 521) has endeavoured to

determine the mol w of Li by measuring the lowering of vapour pressure of Hg produced by dissolving Li in Hg the results make it probable that the mol w of Li is the same as the at w. This result is based on the assumption that Van't Hoff's law holds good, viz, that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved substance, it also presupposes that the molecular weight of liquid Hg is the same as the atomic weight.

As the V D of no Li compound has yet been determined, the valency of the atom Li in gaseous molecules is not certainly known, but from the close analogy between Li and the other alkali metals there can be little doubt that the atom of Li is monovalent in gaseous molecules.

Li is a strongly positive metal, it belongs to the group of alkali metals, none of which shows any tendency to enter into the negative radicle of salts. Li shows closer resemblances to the alkaline earths than are exhibited by any other metal of the alkalis, LiOH , Li_2CO_3 , and Li_3PO_4 are much less soluble in water than the corresponding compounds of Na, K, Rb, and Cs, Li does not form an alum. The position and analogies of Li are discussed in the article ALKALIS, METALS OF THE, vol 1 p 114.

Reactions and Combinations — 1 Li decomposes cold water rapidly without itself melting. Thomsen (*Th* 3, 227) gives the thermal data $[\text{Li}, \text{H O Aq}] = 48,970$ (to form $\text{LiOH Aq} + \text{H}$) — 2 Very rapidly oxidised by conc nitric acid — 3 Slowly acted on by conc sulphuric acid, rapidly dissolved by dilute $\text{H}_2\text{SO}_4\text{Aq}$, also by dilute hydrochloric acid (Matthiessen, *A* 94, 10) — 4 Burns when heated in dry carbon dioxide or sulphuretted hydrogen — 5 At temperatures lower than its melting point Li acts on silica, alkaline silicates, iron, gold, silver, and platinum — 6 Combines readily with sulphur, phosphorus, and the halogens.

Detection — Li compounds give a red colour to a non luminous flame. Examination by the spectroscope will detect 000009 mgrms Li present as LiCl (Bunsen). To detect Li in silicates, the powdered mineral is treated with HFAq, the liquid is poured off, and the residue is evaporated with addition of a little H_2SO_4 , the residue is extracted with absolute alcohol, and the liquid is evaporated to dryness, the residue is again treated with absolute alcohol, and this solution is again evaporated, and the residue ($\frac{1}{10}$ mgm is sufficient) is examined in the spectroscope, if the mineral is non-siliceous, the treatment with HFAq may be omitted. Li is estimated in the form of Li_2SO_4 .

Lithium, antimonate of LiSbO_3 . By adding LiCl to KSbO_3Aq (cf ANTIMONATES, vol 1 p 285).

Lithium, borate of $\text{Li}_2\text{B}_2\text{O}_5$, and hydrates with $5\text{H}_2\text{O}$, $6\text{H}_2\text{O}$, and $10\text{H}_2\text{O}$, by adding Li_2CO_3 to boric acid solution (Arfvedson, *A Ch* [2] 10, 82, Finsinger, *Ar Ph* [3] 8, 198, cf BORATES, vol 1 p 529).

Lithium, borofluoride of By double decomposition between $\text{Ba(BF}_4)_2\text{Aq}$ and $\text{Li}_2\text{SO}_4\text{Aq}$ and evaporation at 40° , large deliquescent prisms are obtained, al sol water, these crystals are probably LiBF_4 , but they have not been accurately examined (Berzelius).

Lithium, bromide of LiBr HF [Li, Br, Aq] = 91,810 (*Th* 3, 227), [Li, Br, Aq] = 11,850 (Bodisko, *J R* 1889 [1] 7) SG 3 102 at 17° (Clarke, *Am S* [3] 13, 293) A white crystalline, very deliquescent, mass Obtained by dissolving Li_2CO_3 in HBrAq and evaporating (Troost, *A Ch* [3] 51, 108), or by ppg excess of CaBr_2Aq by K_2CO_3 , after 24 hours adding enough Li_2CO_3 to ppt all the Ca , filtering, and evaporating (Klein, *A* 128, 239) S 143 at 0° , 196 at 34° , 222 at 59° , 244 at 82° , 270 at 103° (Kremers, *P* 103, 65)

Lithium, chloride of LiCl SG 2 074 at 39° (Schroder, *P* 106, 226), 1998 at 0° , 1 515 at M P (Quincke, *A* 138, 141), SG fused 1 575 (Wermicke, *P* 138, 141) HF [Li, Cl] = 93,810, [Li, Cl, Aq] = 102,250 (*Th* 3, 227) SH 282 (Regnault)

Preparation—1 By dissolving Li_2CO_3 in HClAq and evaporating—2 By decomposing $\text{Li}_2\text{SO}_4\text{Aq}$ by BaCl_2Aq , filtering from BaSO_4 , and evaporating

Properties—Crystallises from aqueous solution in regular octahedra, very deliquescent, more so than CaCl_2 , tastes like NaCl , melts at dark red heat to a clear liquid, which gives off some Cl and becomes alkaline when heated for a long time in the air, the same change occurs to a slight extent when LiClAq is evaporated E sol alcohol, also in a mixture of ether and alcohol in which KCl and NaCl are nearly insoluble Volatilised at white heat S 63 7 at 0° , 80 7 at 20° , 104 2 at 65° , 115 at 80° , 129 at 96° , 139 at 140° , 145 at 160° Gerlach (*Fr* 8, 279) gives the following —

SG LiClAq	Pc LiCl	SG LiClAq	Pc LiCl
1 008	1	1 148	25
1 030	5	1 182	30
1 058	10	1 219	35
1 086	15	1 256	40
1 117	20		

B P of saturated LiClAq = 171° (Kremers, *P* 103, 65)

Reactions—1 Heated in air for some time is partially decomposed with evolution of Cl , residue is alkaline (Schulze, *J pr* [2] 21, 407) Evaporation of LiClAq is accompanied by slight decomposition—2 Completely decomposed by heating in steam, with evolution of HCl , decomposition is rapid in presence of silica, but is prevented by admixture of NH_4Cl (Kunheim, *J* 1861 149)

Combinations—1 With water to form two hydrates (1) $\text{LiCl} \cdot 2\text{H}_2\text{O}$, obtained as quadratic crystals by evaporating LiClAq under 10° Dried between paper, the crystals become opaque and powdery, when warmed, melts in water of crystallisation, then solidifies, and then the dry LiCl melts again at red heat, (2) by evaporating a solution of LiCl in aqueous alcohol, Rammelsberg obtained the monohydrate $\text{LiCl} \cdot \text{H}_2\text{O}$ (*P* 66, 79)—2 With alcohol to form $\text{LiCl} \cdot 2\text{C}_2\text{H}_5\text{O}$, and with methyl alcohol to form $2\text{LiCl} \cdot 3\text{CH}_3\text{O}$, obtained by evaporating solution of LiCl in the respective alcohols (Simon, *J pr* [2] 20, 871)—3 With platinic chloride, to form $\text{Li}_2\text{PtCl}_6 \cdot 6\text{H}_2\text{O}$, orange-red salt, sol in water, alcohol, and ether-alcohol

Lithium, chromate and dichromate of, v. vol u pp 155, 157

Lithium, fluoride of LiF Small crystalline tablets, by dissolving excess of Li_2CO_3 in HFAq , filtering, and evaporating Slightly sol in water, melts at red heat (Berzelius, *A* 1, 17) SG 2 295 at 21.5° (Clarke, *Am S* [3] 13, 292) By solution of LiF in HFAq and evaporation, crystals of LiF HF are obtained, when heated LiF and HF are formed Fluckiger (*A* 87, 261) describes the double salt $2\text{LiF} \cdot \text{SbF}_5$, LiF combines with SiF_4 to form the *silico-fluoride* Li_2SiF_6 (*v* LITHIUM, SILICOFLUORIDE *ov*, p 151)

Lithium, haloid compounds of Lithium combines directly with the halogens, the haloid compounds, LiX , are generally prepared by dissolving Li_2CO_3 in the respective acids and evaporating As the V D of none of the compounds has been determined, their molecular weights are not known with certainty, but from the close similarities between compounds of Li , K , Na , and Cs there can be little doubt that the formula LiX ($\text{X} = \text{F}, \text{Cl}, \text{Br}, \text{I}$) expresses the composition of the molecules of the haloid compounds of Li

Lithium, hydrosulphide of LiSH Obtained by reducing Li_2SO_3 by C , and passing H_2S into a solution of the product Only known in solution (Berzelius, *P* 6, 439) Thomsen gives HF [$\text{Li}, \text{S}, \text{H}, \text{Aq}$] = 66, 120 (*Th* 3, 227)

Lithium, hydroxide of LiOH Obtained by boiling Li_2CO_3 with CaOAq in a silver dish (Pt cannot be used as it is acted on by LiOH), filtering, evaporating, and heating to 100° , better by ppg $\text{Li}_2\text{SO}_4\text{Aq}$ by an equivalent quantity of BaOAq , filtering, evaporating, and heating to 100° Also obtained by dissolving Li_2O (*q v*) in H_2O and evaporating Thomsen (*Th* 3, 227) gives HF [$\text{Li}, \text{O}, \text{H}, \text{Aq}$] = 117, 440, and heats of neutralisation [$2\text{LiOHAq}, \text{H}_2\text{SO}_4\text{Aq}$] = 31,290, [$2\text{LiOHAq}, \text{H}^+\text{Cl}^+\text{Aq}$] = 27,700 Beke toff (*Bl* 41, 312) gives [$\text{Li}^+\text{O}, \text{Aq}$] = 13,000 (to form LiOHAq)

A white crystalline mass which melts when heated, without decomposition, sol in water, but less so than KOH or NaOH , insol in ether alcohol Gmelin obtained small crystals of LiOH by evaporating a solution *in vacuo*, according to Muretow (*B* 5, 331) the crystals are a *hydrate of lithium hydroxide*, $\text{LiOH} \cdot \text{H}_2\text{O}$ (*cf* Dittmar, *S C I* 7, 730)

Lithium, iodide of LiI Obtained by saturating HIAq , containing a little H_3PO_4 , with Li_2CO_3 , warming the ppt Li_3PO_4 with BaI_2 and a trace of H_2SO_4 , filtering, adding enough Li_2CO_3 to decompose excess of BaI_2 present, filtering again, evaporating, crystallising, and drying by pressure between filter paper (Liebig, *A* 121, 222) Liebig (*lc*) also recommends to neutralise half of an HI solution containing a little H_3PO_4 by BaO or CaO , to add the other half of the acid, neutralise by Li_2CO_3 , filter from Ba or Ca phosphate and evaporate The crystals are generally yellowish from a little separated I , this is removed by quickly pressing between filter paper LiI forms small, colourless, deliquescent crystals SG 3 485 at 23° (Clarke, *Am S* [3] 13, 293) HF [$\text{Li}, \text{I}, \text{Aq}$] = 76, 100 (*Th* 3, 227) S 151 at 0° , 164 at 19° , 179 at 40° , 200 at 59° , 263 at 75° , 435 at 80° , 476 at 99° , 588 at 120° (Kremers, *P* 103, 65) By evaporating a solution of Li_2CO_3 in HIAq over H_2SO_4 , Ram

melberg obtained the hydrate $\text{Li}_2\text{S}\cdot\text{H}_2\text{O}$ (P 66, 79)

Lithium, oxide of Li_2O Obtained by burning small quantities of Li, in a small iron vessel, in dry O at 200° , cooling in O, and heating in the air to decompose Li peroxide (Troost, *A Ch* [3] 51, 103) Also prepared by heating Li_2CO_3 with C in a Pt crucible, and by heating LiNO_3 to redness in a Ag dish, best mixed with Cu turnings (H Muller, *J pr* 58, 148)

A white crystalline solid, S G 2 102 at 15° (Brauner & Watts, *P M* [5] 11, 60) Not decomposed by heating with C or Fe Does not act on Pt at high temperatures, corrosion of the Pt vessel in the preparation of Li_2O indicates the presence of H_2O or Cs O Reacts with Cl, S, and P Heated in O, Li_2O is superficially changed to peroxide Thomsen gives $[\text{Li}_2\text{O}, \text{Aq}] = 166.5^\circ$ (Th 3, 227), and Beketoff (*Bl* 41, 312) gives $[\text{Li}_2\text{O}, \text{Aq}] = 13,000$, hence $[\text{Li}_2\text{O}] = 153,520$

Lithium peroxide is said to be formed by heating Li_2O , or Li_2CO_3 , for some time in air or O, but to be decomposed at a little above the temperature of formation

Lithium, phosphide of According to Troost (*A Ch* [3] 51, 103) Li and P combine, when heated together, to form a brown substance which is decomposed by water with evolution of inflammable P hydride

Lithium, silicofluoride of $\text{Li}_2\text{SiF}_6\cdot 2\text{H}_2\text{O}$ Transparent monoclinic crystals, obtained by adding H_2SiF_6 aq to Li acetate or carbonate evaporating, treating the residue with water, filtering, and crystallising (Stolba, *J pr* 91, 456) S 526 at ordinary temperature, sol alcohol, insol ether S G 233 Dehydrated at 100° , melts at a higher temperature with evolution of SiF₄

Lithium, salts of Compounds produced by replacing H of acids by Li The Li salts belong to one series Li_xX , where $\text{X} = 2\text{Cl}, 2\text{NO}_3, \text{SO}_4, \text{CO}_3, \frac{2}{3}\text{PO}_4$, &c, they are generally obtained by dissolving Li_2CO_3 in the different acids, some are prepared by double decomposition from LiCl or Li_2SO_4 Most of the salts of Li are sol in water, but Li_3PO_4 and Li_2CO_3 are considerably less sol than the corresponding salts of the other alkali metals, LiOH is also less soluble than the other alkalis (cf ALKALIS, METALS OF THE, vol 1 p 114) Few, if any, basic salts of Li are known The chief Li salts are the following (v CARBONATES, NITRATES, SULPHATES, &c) *Antimonate, arsenate, borate, bromate, carbonate, chlorate, chromates, ditimonate, hypochlorite, hypophosphite, iodate, nitrate and nitrite, perchlorate, periodate, phosphates, selenate and selenites, silicates, sulphates and nitrite, tellurate and nitrite, thio-arsenate*

Lithium, sulphide of Li_2S Li and S combine when heated together, the solution in water is yellow from presence of polysulphides Li_2S is obtained by reducing Li_2SO_4 by an equivalent quantity of C at full red heat, excess of C makes the product pyrophoric (Berzelius, P 6, 439) Naudin & Mantholon (*C R* 83, 53) say that Li_2S may be prepared by the long-continued passage of H_2S through Li_2CO_3 suspended in water Li_2S is easily sol water and alcohol $[\text{Li}_2\text{S}, \text{S}, \text{Aq}] = 115,260$ (Th 3, 227)

Lithium polysulphides are said to be obtained by melting LiOH with S (Vauquelin,

A Ch 7, 284), they closely resemble the polysulphides of the other alkali metals

Lithium, sulphate of, v LITHIUM, HYDROSULPHIDE OF, p 150 M M P M

LITHO-BILIC ACID $\text{C}_{20}\text{H}_{30}\text{O}_8$ [199?] Occurs, together with lithofelic acid, in Oriental bezoar, and is prepared by decomposing the barium salt with hydrochloric acid and recrystallisation from alcohol Long pale-yellow needles, insol water, v sol alcohol, m sol ether Its alcoholic solution is dextrorotatory It resembles lithofelic and the bilary acids in its behaviour with Pettenkofer's reaction and its distillation products (Roster, *G* 9, 462, Grattarola, *J* 1880, 831) — BaA'_6 aq Ppd by adding BaCl_2 to a warm aqueous solution of crude sodium lithofellate, usually a yellowish semi-transparent resin, was obtained on one occasion in minute monoclinic crystals

LITHOFELIC ACID $\text{C}_{20}\text{H}_{30}\text{O}_8$ [205?] S (alcohol) 3.4 at 20° , 15 at 78° S (ether) 225 at 20° (Göbel) $[\alpha]_D = 13.8$ at 9.5° (independent of concentration) Forms the chief constituent of some kinds of Oriental bezoars (Göbel, *A* 39, 237, Etting, *A* 39, 242, Wöhler, *A* 41, 150, Heumann, *A* 41, 303, Malaguti & Sarzeau, *C R* 15, 518) The finely powdered bezoars are extracted with boiling alcohol, and the solution evaporated The crude acid then deposited is converted into sodium salt, and then into the Ba salt On recrystallising, barium lithobilate remains undissolved, and the solution of barium lithofellate is then decomposed by HCl (Roster, *G* 9, 364) Minute hexagonal crystals (containing aq) (Hoppe Seyler, *Vuchow's Arch.* 25, 528, Grattarola, *J* 1880, 831) Insol water Dextrorotatory Its salts are also dextro-rotatory, somewhat bitter in taste On distillation it gives off aromatic fumes

Reactions — 1 When heated with sugar and H_2SO_4 it gives a crimson colour (Pettenkofer's reaction) (Strecker, *A* 67, 53) — 2 Boiling HClA resinifies it — 3 Hot nitric acid gives a yellow acid, $\text{C}_{20}\text{H}_{30}(\text{NO}_2)_8$, which may be crystallised from HOAc

Salts — The sodium salt forms a pale-yellow gummy mass, exceedingly sol water and alcohol $[\alpha]_D = +18.16$ at 14.5° — BaA'_{10} aq large prisms, sol boiling water and alcohol $[\alpha]_D = +19.7$ at 15° — AgA' flocculent pp

LITHOSPERMUM ERYTHRORHIZON (M Kuhara, *C J* 35, 22) The Japanese prepare a dye called Shikon or Tokio purple from the root of this plant The colouring matter may be extracted by exhausting successively with water and alcohol Lead subacetate is added to the latter extract, and the purple pp washed and decomposed by aqueous H_2S The dye is extracted from the dried pp by means of alcohol It is resinous with green lustre Its composition may be represented by $\text{C}_{20}\text{H}_{30}\text{O}_{10}$ Its alcoholic solution is purple, and shows an absorption spectrum similar to that of alkanet Alkalis turn the solution blue, acids turn it red Baryta gives a purple pp $\text{C}_{20}\text{H}_{30}\text{BaO}_{10}$ The dye is readily oxidised to a brown scaly substance, $\text{C}_{20}\text{H}_{30}\text{O}_{11}$ Bromine forms a product of substitution, $\text{C}_{20}\text{H}_{30}\text{Br}_2\text{O}_{10}$ With PCl_5 it forms a black resinous body, $\text{C}_{20}\text{H}_{30}\text{Cl}_2\text{O}_{10}$

LITHURIC ACID $\text{C}_{15}\text{H}_{15}\text{NO}_8$ (?) [205?] Occurs as magnesium salt in some urinary

calculi of oxen (Roster, *A* 165, 104) Slender, silky needles M sol boiling water and alcohol — MgA_2 , minute monoclinic prisms, m sol boiling water, v sl sol cold water, insoluble in alcohol

LITMUS Obtained chiefly from various species of *Roccella*, *Varolaria*, and *Lecanora*, the same lichens that yield archil The blue colouring matter appears to be developed by fermentation after the mass has been treated with alkaline carbonate (Géhis, *Rev Scient* 6, 50, *J Ph* 24, 277)

When 2 pts of *Roccella tinctoria* and 1 pt of K_2CO_3 are repeatedly moistened with a solution of ammonium carbonate, the mass acquires a fine blue colour in forty days The mass is then mixed with chalk and gypsum

According to Kane (*T* 1840, 298), litmus contains azolitmin, spaniolitmin, erythrolein, and erythrolitmin Azolitmin is a reddish brown amorphous powder, which dissolves in ammonia with blue colour, and forms blue and violet lakes Spaniolitmin was not isolated by Kane, but appeared to be light red According to Kane, erythrolein is a red viscid mass, forming a purple solution in ammonia, while erythrolitmin forms deep red crystalline grains, forming a purple solution in ammonia The method employed by Kane to isolate these substances is as follows Litmus is exhausted with boiling water, the residue is acidified by HCl, again washed, and then boiled with alcohol The alcoholic solution is evaporated to dryness, and the residue extracted with ether, which leaves erythrolitmin undissolved The ether leaves erythrolein on evaporation The reddish brown powder left after boiling with alcohol is impure azolitmin

De Luynes (*C R* 59, 49), by heating orcein with aqueous NH_3 and Na_2CO_3 at 70° , obtained a blue substance, which he regarded as the blue colouring matter of litmus

According to Wartha (*B* 9, 217), cold alcohol extracts from litmus a red substance, which is not affected by acids, and the residue yields to water the blue colouring matter If the aqueous extract be evaporated, and the residue treated with absolute alcohol and some HOAc, a scarlet dye, turned purple by NH_3 , is extracted, while the residue is the pure litmus blue, left as a brown powder

A blue ethereal extract of litmus shows an absorption-band at D, a red ethereal extract shows an absorption-band extending to E (Vogel)

An aqueous solution of litmus, kept in a closed vessel, gradually becomes decolourised This is due to the action of a micrococcus, which reduces the colouring matter to a leuco-derivative, which is readily re-oxidised by air (Dubois, *Bl* [2] 49, 963, cf Bellamy, *J Ph* [5] 18, 483)

According to Förster (*Fr* 28, 428), litmus is best purified by exhausting with alcohol in the cold, digesting with water, filtering, and evaporating The residue is dissolved in water, filtered, and ppd by a mixture of alcohol and HOAc The pp is washed with alcohol, and the solution, ppn, and washing repeated as long as any reddish-violet substance is removed thereby The pp is then dried, dissolved in water, the solution filtered and ppd by feebly ammoniacal

alcohol The pp is finally washed with alcohol and dried

LIVER OF SULPHUR A name formerly applied to a mixture of the polysulphides of potassium, obtained by heating together K_2CO_3 and S in a closed vessel (v POTASSIUM, SULPHIDES or)

LIXIVIATION The application of water to solid mixtures, for the purpose of extracting the soluble parts

LOBARIC ACID $C_{17}H_{16}O_5$ A resinoid acid obtained by extracting the lichen *Lobaria adusta* with ether (Knop, *C C* 1872, 172) Warty masses, made up of thin plates Insol water and baryta water In aqueous or alcoholic NH_3 it forms colourless solutions, which turn rose-red on exposure to air KOHAq forms a yellow solution, turning brown on evaporation.

LOBELINE An alkaloid existing in *Lobelia inflata* (Bastick a Procter, *Ph* 10, 270, 456) Obtained by extracting the leaves with dilute acetic acid, and ppg with magnesia Thick, oily mass, decomposed by heat V sol water, alcohol, and ether Narcotic Forms crystalline salts with HCl, HNO_3 , H_2SO_4 , and oxalic acid Its solutions are ppd by tannin

Lobelia nicotianifolia contains also a second alkaloid, dissolved by HCl, from solutions made alkaline by NH_3 It resembles lobeline in physiological action, and, like it, exhibits no characteristic colour reactions (Dragendorff a von Rosen, *C C* 1886, 873)

LOGANIN $C_{25}H_{34}O_{14}$ [215°] A glucoside found by Dunstan and Short (*Ph* [3] 14, 1025) in the pulp in which the seeds of *Strychnos nuxvomica* are embedded Extracted by alcohol chloroform, and recrystallised from alcohol Prisms V sol water and alcohol, less sol ether, $CHCl_3$, and benzene The aqueous solution is not ppd by reagents for alkaloids, nor by lead acetate or $AgNO_3$ Not coloured by $FeCl_3$, HNO_3 , or H_2SO_4 , and $K_2Cr_2O_7$ Conc H_2SO_4 gives a red colour on warming, changing to purple Loganin does not reduce Fehling's solution Boiling dilute H_2SO_4 splits it up into glucose and loganetin Loganetin is sol water and alcohol, less sol ether and $CHCl_3$ It also gives a purple with H_2SO_4

LOKAOIC ACID $C_{22}H_{18}O_{27}$ (K) or $C_{26}H_{22}O_{31}$ (C a G) *Lokain* The colouring matter of Chinese green, obtained from the berries of the buckthorn (*Rhamnus utilis*), contains lokaonic acid (Kayer, *B* 18, 3417, cf Cloez a Guignet, *J* 1872, 1068) Lokao, the commercial article, consists of calcium and aluminum lokaonates It is decomposed by boiling with ammonium carbonate, and on adding alcohol to the filtrate ammonium lokaonate is ppd This is decomposed by oxalic acid Lokaonic acid is a deep blue or bluish black mass, which exhibits metallic lustre when rubbed It is insol water, alcohol, ether, and chloroform In aqueous alkalis it forms a blue solution, changed to red by mild reducing agents, such as H_2S Boiling dilute H_2SO_4 splits it up into a sugar, lokaose, and lokaonic acid

Salts — NH_4A (at 100°) deep blue pp, with bronze lustre when dry, sol water, insol alcohol — $(NH_4)_2A$ similar to the preceding. Begins to lose NH_3 at 40° — K_2A dark blue

powder — BaA" (at 100°) deep blue powder, insol water — PbA" (at 100°) blue black pp

Lokanic acid $C_{18}H_{16}O_{12}$ (K) or $C_{18}H_{16}O_{12}$ (C a G) *Lokatin*. Obtained by boiling lokaonic acid with dilute H_2SO_4 , dissolving the pp in NH_4Aq and ppg with oxalic acid. Violet black crystalline powder, which exhibits a bronze lustre when rubbed. Insol water, alcohol, ether, and chloroform. Alkalis form a violet solution. At 120° it becomes $C_{18}H_{14}O_{20}$. Conc H_2SO_4 dissolves it in the cold, and on adding water a reddish brown powder, $C_{18}H_{16}O_{16}$, is ppd. This dissolves in NH_4Aq , and the solution gives, with $BaCl_2$, a reddish brown pp, $BaC_{18}H_{16}O_{16}$. Lokaonic acid is decomposed by boiling conc KOH into phloroglucin and delokanic acid. Hot dilute nitric acid forms nitro phloroglucin.

Salts — NH_4A (dried at 100°) bluish black powder, sol water insol alcohol. Dyes cotton, silk, and wool deep violet without mordant. Mixed with $Na_2S_2O_3$, it dyes cotton a permanent sky blue (C a G) — BaA" (dried at 100°) blue black powder, insol water and alcohol. PbA" deep blue powder, insol water and alcohol.

Delokanic acid $C_{15}H_{10}O_8$. Formed as above. Brown powder, insol water, sol alcohol. Its solution in alkalis is cherry red. It reduces Fehling's solution with difficulty in the cold.

Lokaose $C_{18}H_{16}O_8$. A sugar formed by hydrolysis of lokaonic acid. It reduces chloride of gold and Fehling's solution in the cold. It reduces half as much CuO as glucose.

LOPHINE v vol 1 p 474

LOTURINE [234°] Occurs to the extent of 24 p.c., together with 02 p.c. of colloturine and 06 p.c. of loturidine, in lotur bark from *Symplocos racemosa*, growing in India (Hesse, B 11, 1042). The alkaloids are extracted from the bark by hot alcohol, and are converted into acetates. Loturine and colloturine are ppd from the neutral solution by potassium sulphocyanide, leaving loturidine in solution. The crystalline pp is decomposed by Na_2CO_3 , and the alkaloids are extracted with ether and recrystallised from alcohol. The efflorescent crystals of loturine are separated mechanically from the non efflorescent crystals of colloturine.

Properties — Long prisms. May be sublimed. Insol water, sol alcohol, acetone, ether, and chloroform. Its acid solutions exhibit violet fluorescence. It gives no colour with $FeCl_3$, conc H_2SO_4 , HNO_3 , or bleaching powder followed by ammonia. Its hydrochloride forms white prisms. The hydrochloride, nitrate, and chromate crystallise in needles. The platinochloride is a yellow pp.

Colloturine. Long prisms, may be sublimed. Its solutions in aqueous HCl and H_2SO_4 fluoresce violet. Its aurochloride is a yellow amorphous pp.

Loturidine. Extracted from the filtrate from the ppd sulphocyanides of loturine and colloturine by adding NH_3 and shaking with ether. Yellowish brown amorphous mass. Forms amorphous salts. Its solutions in dilute mineral acids fluoresce violet.

LOXOPTERYGINE $C_{22}H_{22}N_2O_2$ [81°] Occurs, together with another alkaloid and tannin, in red Quebracho bark from *Loxopterygium Lorentzii* (Hesse, A 211, 274). Extracted by alcohol,

the alcoholic solution being evaporated, the residue treated with aqueous $NaOH$ and the alkaloids extracted with ether. The acetic acid solution of the alkaloids is mixed with potassium sulphocyanide, which ppts one alkaloid and leaves the loxopterygine in solution, whence it is ppd by ammonia. White amorphous mass, sol cold water, v sol alcohol, ether, chloroform, and benzene. Its solutions exhibit alkaline reaction. Tastes intensely bitter. Conc H_2SO_4 and a little $K_2Cr_2O_7$ gives a violet colour.

LUPANINE $C_{14}H_{12}N_2O$. Occurs in the seeds of the blue lupine (*Lupinus angustifolius*), from which it is extracted by alcohol containing HCl (Hagen, A 230, 370). Viscid yellow liquid with green fluorescence, characteristic smell, and very bitter taste. Sol water, but separates on warming, m sol cold alcohol, v sol ether and chloroform. Not volatile with steam. Strongly alkaline, fuming with HCl .

Salts — $BHCl$ 2aq [127°] M sol water and alcohol, insol ether. The base is set free from this salt by KOH but not by NH_3 — BHl 1½aq yellow crystals (from hot water), sol. CS, insol alcohol and ether — $BHCyS$ ½aq pale yellow crystals, v sol hot alcohol, sl sol water, insol ether — $BH PtCl_3$ 3½aq — $BH AuCl_4$ splendid yellow needles, sl sol ether, insol water and alcohol.

Methyl iodide $BMeI$ [215°] Crystals, sl sol water, insol alcohol and ether. The methyl hydroxide is formed by treatment with Ag_2O but not with KOH .

Methyl chloride $BMeCl$ 2aq [128°] Extremely deliquescent crystals, insol ether — $BMeHPTCl_3$ ½aq red crystals, insol ether, sl sol alcohol — $BMeAuCl_4$ ½ $AuCl_3$ lemon yellow needles.

LUPETIDINE v DI METHYL PYRIDINE HEXAHYDRIDE

LUPINIDINE v LUPININE

LUPININ $C_{25}H_{32}O_{16}$ *Lupinin*. A glucoside in the buds of the yellow lupine (*Lupinus luteus*). Extracted by 50 p.c. alcohol (Schulze a Barbieri, B 11, 2200). Slender yellowish white needles (containing 7aq). Sl sol water and alcohol. Alkalis form a deep yellow solution. Its ammoniacal solution gives a lemon yellow pp with lead acetate. Boiling with water or dilute acids splits it up into glucose and lupigenin.

Lupigenin $C_8H_{12}O_6$. Formed as above. Minute yellow needles, insol water, sl sol alcohol. Forms a deep yellow solution in aqueous NH_3 — NH_4A ¼aq lemon yellow powder.

LUPININE $C_{24}H_{30}N_2O_2$ [68°] (256°) An alkaloid in the seeds of the yellow lupine (*Lupinus luteus*), and extracted by alcohol containing HCl . The extract is evaporated to a syrup, treated with KOH , and shaken with light petroleum. The petroleum is shaken with aqueous HCl , the solution treated with KOH , and the alkaloid extracted by ether, from which it is recrystallised (Baumert, L V 27, 15, cf Beyer, L V 14, 161, v also lupinidine, *infra*).

Properties — Trimetric crystals, may be distilled in a current of hydrogen. Tastes bitter. V sol cold water and alcohol, less sol hot water, v sol benzene, chloroform, and CS_2 . Strong base, liberating NH_3 from its salts and fuming with HCl . In its solutions tannin gives a flocculent pp, phospho-molybdic and phos-

photungstic acids give yellow pps. Iodine gives a dirty brownish red pp.

Reactions — 1 HI gives $C_{10}H_{16}N_2O_2I_2$ — 2 With fuming HCl at 200° it forms anhydro lupinine $C_{10}H_{14}N_2O$ and finally di-anhydro lupinine $C_{10}H_{12}N_2$ (Baumert, A 214, 366) — 3 P_2O_5 heated with the hydrochloride at 180° forms oxylupinine, which with platinum chloride forms $C_{10}H_{10}N_2O_2.H_2PtCl_6$, crystallising in yellow plates. If the mother liquor be heated with P_2O_5 to a higher temperature anhydro lupinine is formed (Baumert, A 214, 360) — 4 Sodium dissolves in fused lupinine, but the product is decomposed by water into NaOH and lupinine (Baumert, B 15, 631)

Salts — $B''H_2Cl_2$ large trimetric crystals — $B''HNO_3$ crystals, v sol water and alcohol — $B''H_2SO_4$ deliquescent prisms — $B''(H_2AuCl_4)_2$ needles, v sl sol water — $B''H_2PtCl_6$ crystals, sol water

Acetyl derivative $C_{10}H_{14}Ac_2N_2O_2$ Obtained by heating lupinine with $AcCl$ or with Ac_2O and $NaOAc$ (Baumert, A 224, 313) Oil — $B''H_2PtCl_6$ orange trimetric plates

Methylo-iodide $B''Me_2I_2$ white hexagonal plates, sl sol alcohol (Baumert, B 14, 1221)

Methylo-chloride $B''Me_2Cl_2$ pearly plates — $B''Me_2PtCl_6$ orange red needles — $B''Me_2Au_2Cl_6$ yellow pp

Ethyl-iodide $B''Et_2I_2$ hexagonal plates (Baumert, B 14, 1321) Decomposed by AgO, but not by KOH. From it may be obtained $B''Et_2PtCl_6$ and $B''(Et_2AuCl_4)_2$ [70°]

Anhydro-lupinine $C_{10}H_{14}N_2O$ Formed by heating lupinine with fuming HCl at 150° – 200° (Liebscher, B 14, 1880) Liquid which cannot be distilled. Oxidised by air. Smells like conine. Forms crystalline salts — $B''H_2PtCl_6$ red tables, v sol water

Di-anhydro-lupinine $C_{10}H_{12}N_2$ (220°) From lupinine and conc $HClAq$ at 200° (Liebscher, A Baumert, A 214, 371) Oil. Readily oxidised by air — $B''H_2PtCl_6$ dark red crystals, v sol warm water

Lupidine $C_{10}H_{16}N_2$

Preparation — Lupine seeds are extracted with dilute alcohol acidified with H_2SO_4 , and, after as much fat as possible has been removed, the sulphate solution is evaporated to a syrup and the residue triturated with absolute alcohol, when it solidifies to a mass of crystalline plates. This mass is again triturated with absolute alcohol, when a white crystalline meal of acid lupidine sulphate separates. The mother liquors are treated again in the same manner, until the residue, on trituration with alcohol, either remains liquid or at least redissolves on washing with absolute alcohol, in this case it consists for the most part of lupinine sulphate. The mother liquors containing the lupinine sulphate are freed from alcohol, dissolved in water, and ppd by $BaCl_2$. The filtrate now contains chiefly lupinine chloride, from which any lupidine salt present can be ppd as platinum chloride (G Baumert, A 225, 365) Lupidine is obtained by decomposing the acid sulphate by one of the stronger bases, shaking with ether, and distilling in a current of hydrogen. The fact that this alkaloid distils over in a stream of hydrogen, between the wide limits of 250° – 320° ,

is explained on the assumption that the lupidine got from the seeds of the yellow lupine is a mixture of crystallisable hydrate (see below) and a liquid anhydride. The formula $C_{10}H_{16}N_2$ is calculated from analyses of its salts

Properties — Thick yellow oil of intensely bitter taste and disagreeable hemlock like smell, but this smell is probably due to a decomposition product. Strong base. Very easily oxidisable by the air when in contact with acids or with KOHAq, but not with NH_4Aq . Gives no acetyl derivative or ethylo iodide (Baumert, A 225, 365) Lupidine is a feeble poison, acting on frogs like curare (Kobert, A 227, 219)

Salts — $B''HCl$ yellow deliquescent crystals — $B''HI$ rather large crystals resembling alum, v sol hot water, m sol alcohol — $B''H(?)$ Formed by heating lupidine with EtI . Thus lupidine resembles berberine in giving a hydroiodide when heated with EtI (Baumert, A 227, 207) — $B''H_2SO_4$ minute crystals, v sol water, v sl sol alcohol — $B''H_2PtCl_6$ 2aq trimetric crystals, $a b c = 885 \ 1 \ 1171$ (Lueddecke, Z K 12, 297), sl sol water, m sol $HClAq$, v sol dilute alcohol (Baumert, A 225, 365)

Hydrate $C_{10}H_{16}N_2aq?$ The liquid and crystalline portions of the lupine alkaloid are to be considered as modifications of the same base (the hydrate being crystalline), since both yield the same double salt with $PtCl_6$. The existence of a hydrate, stable only in the cold, may also explain why cold aqueous solutions of lupidine, lupinine, and conine become milky on heating. A further proof of the correctness of this view is that the yellow oil only (probably the pure anhydride $C_{10}H_{14}N_2$) was got on treating the lupidine with P_2O_5 (Baumert)

Lupinine A crystalline alkaloid, called by this name, was obtained by Betteli (G 11, 240) by extracting white lupine (*Lupinus albus*) with alcohol. It forms white needles, v sol water. An alcoholic extract of the plant has been used with some success in cases of intermittent malarial fever. Solutions of the alkaloid give white pps with tannin, $HgCl_2$, and $AgNO_3$, in the last case reduction soon takes place. Platine and gold chlorides and picric acid give canary yellow pps. $HIAq$ containing iodine gives a red amorphous pp. It does not reduce Fehling's solution. Boiling KOH gives off ammonia

Lupinine A liquid alkaloid, also called lupinine, was obtained by Campani (G 11, 237) from the white lupine. It boiled between 210° and 218° and was poisonous

The young shoots of the yellow lupine contain an alkaloid called ARGEMINE ($q v$). The danger to sheep from eating lupines appears to be due to another substance 'ictiogen,' perhaps produced by a parasite growing on the lupines (Baumert, Ar Ph [3] 24, 49, Kobert, A Liebscher, J 1886, 1696, Kühn, *ibid*)

LUPULIN The yellow granular aromatic powder situated at the base of the cones of the hop and forming from 8 to 18 p.c. of the cones. It contains hop oil, a resin, a nitrogenous substance, a gummy substance, and a bitter principle. Lerner (D P J 179, 54) extracted the bitter principle by ether, shook the ether with aqueous KOH, ppd by $CuSO_4$, decomposed the copper compound with H_2S , and recrystallised from ether. He describes

the 'lupulin' so obtained as large white prisms, insol water, v sol alcohol, ether, and chloroform. The alcoholic solution, diluted with water, had a bitter taste and acid reaction. Lerner also obtained a compound $[110^\circ]$ which likewise formed a copper salt. Lupulic acid, as described by Bungener, appears to be Lerner's lupulin Isleib (*Ar Ph* [3] 16, 345) found a 'pseudo glucoside' $C_{10}H_{16}O_{10}$ which he extracted by cold water. The extract was treated with animal charcoal, the charcoal dried and exhausted with 90 p c alcohol, and the yellow solution partially evaporated. A brown resin $C_{10}H_{16}O_2$ is deposited while a bitter uncrystallisable substance remains in solution. From the aqueous solution of this bitter substance ether extracts only the bitter principle (which amounts to 0.04 of the hops) and leaves in the water $C_{10}H_{16}O_2$, a tasteless product of the oxidation of oil of hops $C_{10}H_{16}O$. The bitter principle, according to Isleib, forms a yellow solution in alkalis, and is split up by boiling dilute H_2SO_4 into lupuluretin $C_{10}H_{16}O_2$ and lupulic acid $C_{10}H_{16}O_4$. This lupulic acid forms a crystalline barium salt $BaC_{10}H_{16}O_4 \cdot 5aq$. According to Bissell (*Ph* [3] 8, 508) lupulin does not contain all the active principle of the hop. The bitter principle may usually, but not always, be ppd from an infusion of hops by lead acetate (Allen *Ar* 13, 43). According to Hayduck (*U C* 1887, 694), when hops are exhausted with ether, and after evaporating the ether, the residue is treated with alcohol, a white wax is left behind. The alcoholic solution gives a yellow pp with lead acetate, and the filtrate contains two resins, one soluble, and the other insoluble, in light petroleum.

Lupulic acid $C_{10}H_{16}O_4$ [93°]

Preparation—By extracting hop flour with light petroleum spirit, distilling off the solvent, cooling, filtering off the black liquid from the crystals formed, and recrystallising the crude acid from alcohol and petroleum spirit.

Properties—Colourless prismatic crystals, rapidly altered by exposure to the air. V sol alcohol, ether, benzene, $CHCl_3$, CS_2 , and the ethereal oil of the hop, sol petroleum spirit, insol water. Easily reduces ammoniacal $AgNO_3$. Exposed to the air is transformed into a yellowish resin. This product of oxidation is sol water, to which it imparts an intense bitter taste, and this resin is the bitter principle of the hop—CuA'. A crystalline powder (Bungener, *Bl* [2] 45, 487).

LUPULINE v HOPPING

LUTEIC ACID $C_{10}H_{16}O_{12}$ (?) [274°] S

0.09 in the cold, 0.3 at 100° S (alcohol) 4.2 in the cold S (ether) 37. A yellow colouring matter prepared from the flowers of *Euphorbia Cyparissias* (Hohn, *Ar Ph* [2] 140, 218). The fresh flowers are exhausted with alcohol of 60 p c, the greater part of the alcohol distilled off, and the residual liquid filtered and ppd with basic lead acetate. The pp is suspended in water, decomposed by H_2S , and filtered. The filtrate is evaporated over H_2SO_4 , and the yellowish crusts that separate are recrystallised from ether-alcohol, and then from hot water containing 4 p c of alcohol. Slender yellow needles. Has no smell and a bitter taste. Sublimes at 220° . Its solutions exhibit acid reaction. Lutein somewhat resembles luteolin and,

like the latter, gives protocathechuic acid by potash fusion. It dissolves in caustic and carbonated alkalis forming yellow solutions. It reduces $AgNO_3$, mercurous nitrate, and Fehling's solution on heating. $FeCl_3$ gives a green colour, changing to reddish brown on further addition of $FeCl_3$. Conc H_2SO_4 dissolves luteic acid, but water reprecipitates unaltered. Boiling dilute H_2SO_4 does not attack it.

LUTEIN This name is given by Thudichum (*Pr* 17, 253) to the yellow substance obtained by Piccoli and Lieben (*Z* 1868, 645) from the ovary of the cow, and called by them 'hæmolutein' (*cf* Holm, *Z* 1867, 779). It occurs also in the human ovary. The same or a similar substance occurs in butter, yolk of egg, serum of blood, in some diseased swellings, in carrots, &c. It occurs also in the retina of the eyes of fowls (Capranica, *J Th* 1877, 317, Kuhne, *J Th* 1877, 317). According to Maly (*C C* 1881, 485, *M* 2, 359), the lutein in yolk of egg of hens and shrimps is a mixture of vitello lutein and vitello rubin. If the yolk is extracted with alcohol, and the extract treated with hot baryta water, vitellorubin is ppd while vitellolutein remains in solution. Or the yolk extract may be boiled with a little acid, and the ppd albumen treated with petroleum which extracts vitellolutein, while CS_2 extracts vitellorubin from the residue. Vitellorubin contains no nitrogen. It is red, and forms a Mg compound sol ether, chloroform, and CS_2 , but ppd by alcohol in red flakes. An alcoholic solution of vitellorubin shows a broad but weak absorption band including the line F. Vitello lutein forms a yellow alcoholic solution which exhibits two narrow absorption bands, one including F, the other between F and G. It contains no nitrogen.

LUTECHROMIUM SALTS, v vol II p 160

LUTECOBALTIC SALTS, v vol II p 228

LUTEOLIN $C_{15}H_{18}O_4$ (Moldenhauer, *A* 100, 180) or $(C_{15}H_{18}O_4)_2$ 3aq (Schutzenberger a Paraf, *A Suppl* 1, 256) [320°] S 0.07 in the cold, 0.2 at 100° S (alcohol) 2.7 S (ether) 16. The yellow colouring matter of weld (*Reseda luteola*) (Chevreul, *J Chim Méd* 6, 157). Obtained by boiling weld with water (16 pts) mixed with alcohol (1 pt), filtering, evaporating, dissolving the yellow flakes in alcohol, and pouring into water. It is recrystallised from a mixture of water and glycerin (Rochleder, *J pr* 99, 433). Yellow, four sided needles in radiate groups. May be sublimed. Partially decomposed on fusing. Has a slightly bitter, astringent taste. Reddens litmus slightly. Dissolves with deep yellow colour in caustic and carbonated alkalis. Conc H_2SO_4 forms a yellow solution, whence water reprecipitates it. Potash-fusion gives CO_2 , phloroglucin, and protocathechuic acid. Very dilute $FeCl_3$ gives a green pp, excess of $FeCl_3$ forms a brownish red solution. Alcoholic lead acetate gives a pp $C_{15}H_{18}PbO_4$ aq.

(β -LUTIDINE $C_{15}H_{18}N$ Ethyl pyridine (?) Mol w 107 (166°) SG ρ 956 (W), 959 (C) VD 3.79 (calc 3.70) S 4 (W). Obtained, together with homologues, by distilling cinchonine with KOH, a mixture of some ten bases is obtained and these are separated by fractional distillation (Greville Williams, *J*

1855, 549, 1864, 487, *Pr* 18, 305, Oechsner de Coninck, *C R* 92, 413, *Bl* [2] 85, 296, *R T C* 1, 132, *A Ch* [5] 27, 462, 488) The same base appears to be formed by distilling with zinc dust the syrupy acid formed by oxidising cinchonine with chromic acid mixture (Weidel & Hazura, *M* 3, 780) This, or an isomeric ethyl pyridine, is formed by distilling brucine with KOH (O de Coninck, *Bl* [2] 42, 100) Liquid, sl sol water, sol alcohol and ether The aqueous solution does not become turbid on warming, the base being more soluble in hot than in cold water It appears to form an unstable hydrate $C_8H_9NH_2O$ Smells somewhat like nicotine Physiologically it is a violent poison and stops tetanus produced by strychnine (Greville Williams & Waters, *Pr* 32, 162) By chromic acid mixture or by $KMnO_4$, it is oxidised to pyridine carboxylic (nicotinic) acid [231°] When heated with sodium it appears to form di (β) lutidine $C_{16}H_{18}N_2$ (Greville Williams, *Pr* 33, 159) Chlorine passed into (β) lutidine containing dissolved iodine appears to form tri-chloro (β)-lutidine Chloroacetic acid gives $C_8H_7NClCH_2CO_2H$ (163°) forming ($C_8H_7NO_2Cl$), $PtCl_2$, 2aq (Pictet, *J* 1882, 1079)

Salts — $BHCl$ Very deliquescent crystals — B_2HBr — $B_2H_2PtCl_4$, orange red leaflets Its ppp is not retarded by presence of excess of HCl (difference from bone oil lutidine) Hot water decomposes it forming B_2PtCl_4 crystallising in pale yellow leaflets — B_2PtCl_4 From platinous chloride (1 pt) and lutidine (1 pt) combination takes place with rise in temperature (of 70°), the product being a hard brittle mass (Williams) — B^+HAuCl_4 Yellow pp On boiling with water it forms yellow $B^+HAu_2Cl_4$ and ultimately B^+AuCl_4 , a red crystalline powder — $B_2H_2PdCl_4$, garnet red prisms, obtained by mixing solutions of the hydrochloride and of palladium chloride (W) Decomposed at 100° , giving off HCl and leaving B_2PdCl_4 , sl sol water — $B_2H_2Cl_4U_2O_2Cl_4$ Formed from uranyl chloride and (β) lutidine hydrochloride Yellow — $B_2H_2SO_4(U_2O_2)(SO_4)_2$ From uranyl sulphate and (β) lutidine sulphate Small yellow needles —Picrate $B^+C_6H_7(NO_2)_3OH$ Yellow needles (Williams, *Pr* 33, 159)

Combinations — B_2CuSO_4 , 4aq When (β) lutidine is added to a solution of cupric sulphate a copious pale green pp is formed, which dissolves in excess, forming a rich blue liquid, which deposits blue prisms of B_2CuSO_4 , 4aq — B_2AgNO_3 Formed by ppg silver nitrate solution with (β)-lutidine and recrystallising from alcohol

Di (β) lutidine When sodium is warmed with (β) lutidine dissolved in toluene a product is obtained from which it is possible to get a platinochloride containing a percentage of platinum corresponding to the formula $C_{16}H_{18}N_2H_2PtCl_4$ (Williams, *C N* 44, 308)

Tetra- (β)-lutidine When sodium is warmed with (β)-lutidine a violent action takes place, and from the product a platinochloride may be obtained containing a percentage of platinum corresponding to the formula $C_{32}H_{36}N_4H_2PtCl_4$ (Williams)

Hydride of (β)-lutidine C_8H_7N Greville Williams found that sodium amalgam had no

action on (β) lutidine According to Oechsner de Coninck (*Bl* [2] 42, 121), however a hexahydride (155° – 160°) may be formed by the action of sodium on an alcoholic solution of the base (cf Wyschnegradsky, *B* 13, 2401) It combines with MeI and the product, when distilled with KOH , yields C_8H_7N (160°) It also combines with EtI , and the product treated with potash yields a tertiary base boiling at 175°

Lutidine C_8H_7N (173°) Obtained by distilling strychnine with zinc dust (Seichlani & Magnanini, *G* 12, 445) Yellow liquid, insol water, sol alcohol and ether Smells like pyridine Gives with sodium phosphomolybdate a dark yellow pp, sol ammonia Potassium mercuric iodide gives a yellow amorphous pp Mercuric chloride gives a white pp Iodine in $KIAq$ gives a crimson pp, insol dilute $HClAq$

LYCACONITINE v **ACONITE ALKALOIDS**

LYCINE The base from *Lycium barbarum* to which this name was applied has been shown to be identical with betaine

LYCOPODINE $C_{11}H_{12}N_2O$, [115°] Occurs in *Lycopodium complanatum* (club moss), from which it is obtained by extracting the root with alcohol, evaporating the extract, dissolving the residue in water, adding lead subacetate, removing excess of lead by H_2S , adding $NaOH$, and shaking with ether When the ether is evaporated the alkaloid is left, and may be purified by dissolving in $HClAq$ and ppg with conc $NaOHAq$ (Bodeker, *A* 208, 363) Monoclinic prisms, v sol most menstrua Taste: bitter — $B^+H_2Cl_4$, aq glassy hexagonal crystals (Solling, *J* 1884, 463) — $B^+(HAuCl_4)_2$, aq small glistening yellow needles

LYCOPODIUM BITTER The alcoholic and aqueous extracts of *Lycopodium clavatum* are evaporated, and the residues mixed and extracted with water The solution is treated with lead acetate and subacetate, filtered, freed from lead by H_2S and evaporated The residue is then washed with alcohol and dissolved in water From this solution lead subacetate ppt the bitter principle, and the pp is then suspended in water and decomposed by H_2S The filtrate is concentrated, freed from sugar by careful fermentation with yeast, dried, and extracted with absolute alcohol, which leaves the bitter principle on evaporation (Kamp, *A* 100, 300) Slender needles (from water) v e sol water, alcohol, and ether Extremely bitter Neutral to litmus Contains no nitrogen Colours tincture of iodine orange red Does not reduce Fehling's solution, but after boiling with dilute H_2SO_4 , it does so

LYCOPODIUM OIL The oil from the fresh spores of club moss contains phytosterin $C_{27}H_{48}O$, together with glyceryl ethers of lycopodine

$C_{15}H_{31}O_2$, oleic, arachic, stearic, and palmitic acids (Bukowski, *Chem Zeit* 1889, 174, cf Langer, *Ar Ph* [3] 27, 625)

LYCOPESIN $C_{21}H_{40}O$ [170°] Extracted from *Lycopodium chamæcyparissus* by alcohol, and remaining in the mother liquor after lyco stearone has separated (Kamp, *A* 100, 300) Minute crystals, almost insol boiling water, v sol alcohol and ether, v sol cold alkalis

LYCOSTEARONE $C_{21}H_{40}O_2$ [75°–100°] An amorphous tasteless substance, which may be extracted by alcohol from *Lycopodium chamæcyparissus* (Kamp, *A* 100, 300)

parissus (Kamp, *A* 100, 300) Insol cold water, sol hot water forming a jelly on cooling SL sol cold alcohol and ether, v sol alkalis

LYDINE A violet dye obtained by pouring a solution of aniline (100 g) in fuming $HClAq$ (100 g) diluted with water (120 cc) into a solution of K_2FeCy_6 (90 g) in water (850 cc), and heating the mixture to boiling. The product is dissolved in dilute oxalic acid and ppt by alkalis Violet powder, sol alcohol, sl sol ether and benzene, insol water Poisonous (Guyot, *C R* 69, 829) Possibly identical with mauvine.

M

MACLEYIN $C_{10}H_{15}NO_3$ (?) [201°] S ($CHCl_3$) 7 S (ether) 1 An alkaloid in *Macleya cordata* the Japanese *Tachibaku* (Eijkman, *R T C* 3, 182, *Ph* [3] 13, 87) Extracted from the root by alcohol and dilute H_2SO_4 , and separated from sanguinarin by ether in which it is very slightly soluble Prisms Almost insol water and alkalis, v sl sol hot alcohol Its salts have a bitter taste Its chemical properties resemble those of protopine Conc H_2SO_4 gives a faint yellow changing through violet to green Fumes of nitric acid give an ultramarine colour H_2SO_4 and a little $K_2Cr_2O_7$ give a blue colour

Salts — $B'HCl$ Prisms S 7 — $B'H.PtCl_2$ 2aq yellowish whitepp — $B'H Cr_2O_7$ orange prisms — Hydroiodide crystalline sphres — Normal sulphate colourless needles Thiocyanate needles — Acetate needles — Acid oxalate crystals — Acid tartrate needles — Benzoate [166°] long needles

MACLURIN $C_{11}H_{19}O_6$ (H a P), $C_{11}H_{19}O_6$ (L) *Morintarnic acid* [200°] (Wagner) S 52 at 14° Occurs, together with morin (q v), in old fustic, the wood of *Morus tinctoria*, from which it is obtained by extracting with water The evaporated extract deposits morin, and from the filtrate maclurin may be pptd by HCl (Hlasiwetz a Pfander, *A* 127, 352, *J pr* 94, 65, Löwe, *Fr* 14, 117, Benedikt, *A* 185, 114) Almost pure maclurin is also found in patches in the wood (Wagner, *J* 1850, 529)

Properties — Yellow, crystalline powder (containing aq), v sol alcohol and ether, sl sol water Above 270° it gives CO_2 and pyrocatechin Its aqueous solution is pptd by alkaloids, gelatin, and albumen $FeSO_4$ gives a greenish black pp Its alkaline solution turns brown in air It dyes mordanted cotton pale brownish-yellow Boiling conc KOH aq gives phloroglucin and protocatechuic acid $C_{11}H_{19}O_6 + H_2O = C_6H_6O_3 + C_5H_8O_3$ Dilute H_2SO_4 at 120° does the same Bromine gives tri bromo maclurin $C_{11}H_5Br_3O_6$ aq minute needles Conc H_2SO_4 at 190° gives brown $C_{10}H_{11}O_5$ (Hlasiwetz, *A* 143, 308) Reduction with zinc and H_2SO_4 gives phloroglucin and machronin When its solution is heated with sodium amalgam and the product acidified, ether extracts phloroglucin and amorphous $C_{11}H_{19}O_6$, which is sol water and alcohol, is pptd by lead acetate, gives a grass green colour with $FeCl_3$, and reduces $AgNO_3$ and Fehling's solution.

Salts — $PbC_{11}H_{19}O_6$ aq yellow crystals — $C_{11}H_{19}O_6$ 3 PbO (L)

Acetyl derivative $C_{11}H_{17}AcO_6$ 14aq viscid oil

Macronin $C_{11}H_{19}O_6$ 3aq (?) Formed by the action of zinc and dilute H_2SO_4 on maclurin, and separated from phloroglucin by pptn with lead acetate The pp is decomposed by H_2S Colourless spangles composed of tufts of minute needles (from dilute alcohol) V sl sol water and alcohol, m sol ether Turns dark blue when exposed to air or when heated The hot aqueous solution turns violet blue in air, and then yields an indigo blue pp with HCl $FeCl_3$ gives, in a very dilute alcoholic solution, a violet-red colour, changing to blue Alkaline solutions also turn blue on exposure to air $AgNO_3$ gives a violet colour with reduction of silver Reduces hot Fehling's solution Conc H_2SO_4 gives an orange solution, turning emerald green on warming or diluting

Rufumoric acid $C_{10}H_{17}O_6$ (?) Obtained by boiling maclurin with dilute HCl (Wagner, *J* 1851, 420) Dark red mass, v sol alcohol, m sol water, v sl sol ether Forms a crimson solution in alkalis

MACROCARPINE v THALICTRINE

MADDER v OXY ANTHRACINONES

MAGDALA RED $C_{10}H_7N_3Cl$ Formed by heating naphthalene azo (a) naphthylamine with (a) naphthylamine hydrochloride (Hofmann, *B* 2, 374, 412) Appears to be a compound of amidonaphthazine $C_{10}H_5(NH) \begin{smallmatrix} \diagup N \\ | \\ \diagdown N \end{smallmatrix} C_{10}H_5$ allied to saf-franine, viz

$C_{10}H_5(NH_2) \begin{smallmatrix} \diagup N \\ | \\ \diagdown NCl(C_{10}H_5NH_2) \end{smallmatrix} C_{10}H_5$ (Julius, *B* 19, 1365)

MAGNESIA *Magnesium oxide* MgO (q v)

MAGNESIA ALBA A basic carbonate of Mg, varying somewhat in composition, v Carbonates vol 1 p 699

MAGNESIA USTA. A name given in pharmaceutical nomenclature to MgO prepared by calcining *magnesia alba*

MAGNESIUM At w 24 Mol w probably same as at w (v infra) [c 450°] (Devillea Caron, *A* 101, 359), [c 500°] (Ditte, *B* 73, 108), [between 700° and 800°] (V Meyer, *B* 20, 497) Scarcely volatilises in CO at red to white heat (V. M. Lc.). S G. 1.69 to 1.71 at 17° (Kopp);

1 77 at 0° (Wurtz, *Am Ch* 1876 (March)) S H 20° to 51° 245 (Kopp, *T* 155, [1] 71) C E at 40° 00002694 (Fizeau, *C R* 68, 1125) T C (Ag=100) 84.3 (Lorenz, *W* 18, 422) E C (Hg at 0°=1) 22.84 at 0°, 16.34 at 100° (Lorenz, *W* 18, 422, 582) S V S c 141 Characteristic lines in emission spectrum 5527.4, 5183, 5172, 5166.7 (Thalén, Upsala, 1868, v also Liveing & Dewar, *Pr* 44, 241)

Occurrence—The metal does not occur native, but compounds of Mg are very widely distributed, and are found in some places in large quantities, they usually accompany Ca compounds *Magnesite* $MgCO_3$, *dolomite* a mixture of the isomorphous carbonates of Mg and Ca, *kieserite* $MgSO_4 \cdot H_2O$, *carrollite* $MgCl_2 \cdot KCl \cdot 6H_2O$, various silicates e.g. *asbestos* $(MgCa)SiO_3$, *spinnelle* $MgAl_2O_3$, &c, occur as minerals. Borate, phosphate, sulphate, chloride, nitrate, and hydroxide, of Mg are found in mineral waters, and some of them in sea water. Mg compounds, chiefly phosphate and carbonate and compounds of organic acids, are found in plants and animals.

Magnesia alba (a basic carbonate of Mg) was introduced as a medicine in the beginning of the 18th century, the name is said to have been given merely in contradistinction to *magnesia nigra*, a term applied to the mineral pyrolusite because of its colour and supposed magnetic properties. Magnesia was long supposed to be the same, or nearly the same, as lime. Hoffmann, Bergmann, Margraff, and especially Black (1755) established the characteristic properties of magnesia. Black showed *magnesia alba* to be a compound of fixed air (CO_2) with an earthy base, to this base he gave the name magnesia. In 1800 Davy obtained a small quantity of a metal by reducing magnesia at white heat by vapour of K, in 1830 Bussy obtained the metal in greater quantity and purity, by heating together $MgCl_2$ and K.

Formation—1 By heating together $MgCl_2$ and K in a Pt crucible, and washing out KCl by water (Bussy, *Buff*, *P* 18, 140, Liebig, *P* 19, 137)—2 By electrolysis fused $MgCl_2$ (Bunsen, *A* 82, 137), or a mixture of $MgCl_2$ and KCl with a little NH_4Cl (Matthiessen, *C J* 8, 107)—3 By reducing a molten mixture of $MgCl_2$, CaF_2 , KCl, and NaCl, by Na (Deville & Caron, *C C* 1863 993)—4 By reducing MgF_2 , NaF by Na (Tissier, *C R* 56, 848)—5 By electrolysis a mixture of $MgSO_4$ and $(NH_4)_2SO_4$ dissolved in water (Gerhard, *English Patents*, No 16,691, 1884)—6 Puettner patented a method for reducing $MgCO_3$ by heating with Fe_2O_3 and C (*German Patents*, No 31,319)—7 Lauterborn reduces a double Mg Na cyanide by Zn (*German Patents*, No 39,915).

Preparation—1 The upper part of a porcelain crucible is divided vertically into two halves by a thin porcelain plate, the crucible is closed by a porcelain cover, through which pass the carbon electrodes of a battery of 8-10 Bunsen cells, one electrode on each side of the dividing vertical plate, indentations are cut in the negative electrode, the crucible is heated to redness, then filled with fused $MgCl_2$, and the current is passed through the molten mass. The Mg lodges in the cavities of the negative electrode, and is thus prevented from floating to the surface,

the dividing plate serves to prevent contact between the Cl₂ evolved at the positive electrode, and the Mg (Bunsen, *A* 82, 137)—2 A mixture of $MgCl_2$ and KCl, prepared by evaporating a mixture of the salts, in the ratio 4 $MgCl_2$, 3 KCl, to dryness, is mixed with a little NH_4Cl , and is electrolysed when fused in the apparatus described in 1, as Mg is heavier than the molten mixture of salts it is not necessary to form serrations in the negative electrode (Matthiessen, *C J* 8, 107)—3 A mixture of 6 pts dry $MgCl_2$, 1 pt of a mixture of 7 pts NaCl and 9 pts KCl, 1 pt powdered CaF_2 , and 1 pt Na carefully freed from oil, is heated to bright redness in a covered earthen crucible. The Mg, which separates in globules, is heated nearly to whiteness in a boat of compact charcoal, placed in an inclined tube of the same material through which is passed a stream of dry H, the Mg condenses on the upper part of the tube, it is then melted into large globules with a flux of $MgCl_2$, NaCl, and CaF_2 . To free the Mg from C, Si, and N, it may be distilled in a current of H at a high temperature (Deville & Caron, *A* 83, 137, for an apparatus in which the distillation may be conveniently conducted v Sonstadt, *J pr* 90, 307). In a later trial D & C used 7 pts $MgCl_2$, 4.8 pts CaF_2 , and 2.3 pts Na (*C C* 1863 993)—4 Wöhler (*A* 101, 362) reduces a fused mixture of $MgCl_2$, NaCl with excess of NaCl by Na, the mixture is obtained by adding excess of NaCl to $MgCl_2$ aq and evaporating to dryness. The amount of $MgCl_2$ in the mixture must be known in order that the quantity of Na to be used may be calculated, for every 1 pt $MgCl_2$, about $\frac{1}{2}$ pt Na should be used.

Properties—A silver white, very lustrous, moderately hard, metal, malleable, not very tenacious, may be filed and polished, S G c 1.75 Mg occludes c $\frac{2}{3}$ its volume of H, by heating *in vacuo* the H is suddenly evolved. Obtained in lustrous, white, crystals, hexagonal, $a:c=1.1689$, isomorphous with Zn (Des Cloix, *zeaux*, *C R* 90, 1101). Unchanged in dry air, superficially oxidised in ordinary air. Heated in air, burns to MgO giving out a brilliant white light, very rich in actinic rays. Burns when heated in steam, also in CO_2 , and in SO_2 . Combines directly with the halogens, S, P, As, N. Hot water is slowly decomposed by Mg. Dissolves readily in dilute acids.

Mg is a distinctly metallic element, it forms one series of salts MgX_2 , where $X=Cl, NO_3, \frac{1}{2}SO_4, \frac{1}{2}PO_4$, &c, a few basic salts, and many double salts, are known. In its chemical relations, Mg is analogous to the alkaline earth metals Ca, Sr, and Ba, and also to the metals Be, Zn, Cd, and Hg. MgO and $MgO \cdot H_2O$ are alkaline, $MgO \cdot H_2O$ is formed by the reaction of H_2O and MgO , and is dehydrated to MgO by heat. As the V.D. of no binary compound of Mg with H or one of the halogens has been determined, the valency of the atom of Mg in gaseous molecules is not known with certainty, but from the close similarities between Mg, Zn, and Cd, there is little doubt that the atom of Mg is divalent in gaseous molecules (v MAGNESIUM GROUP OF ELEMENTS, p 163, cf. ALKALINE EARTHS, METALS OF THE, vol 1 p 112).

The atomic weight of Mg has been determined (1) by determining SO_4 in $MgSO_4 \cdot 7H_2O$

(Gay Lussac, *A Ch* [2] 13, 308, Scheerer, *P* 69, 555), (2) by converting MgO into MgSO_4 (Berzelius, *P* 8, 188, Svanberg a Nordenfeldt, *J pr* 45, 474, Jacquelin, *A Ch* [3] 32, 202, Marignac, *A Ch* [6] 1, 289), (3) by converting $\text{MgCO}_3 \cdot 2\text{H}_2\text{O}$ into MgO (S a N 1c), (4) by converting MgCO_3 into MgO (Marchand a Scheerer, *J pr* 50, 385), (5) by determining Cl in MgCl_2 by ppn with Ag (Dumas, *A Ch* [3] 55, 189), (6) by determining S H of Mg

Molecular weight of magnesium—Ramsay (*C J* 55, 521) has determined the lowering of vapour pressure of Hg produced by dissolving Mg in Hg, the results make it probable that the molecular weight of Mg is the same as the atomic weight. This conclusion assumes the accuracy of Van't Hoff's law, that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved substances, and it also supposes the molecular weight of liquid Hg to be the same as the atomic weight of Hg

Reactions—1 Slowly oxidised in moist air—2 Decomposes warm water slowly, heated in steam burns to MgO —3 Heated in air or oxygen to above its M P burns to MgO , with brilliant white light, rich in actinic rays—4 Heated in chlorine, bromine, or iodine forms MgCl_2 , MgBr_2 , or MgI_2 —5 Heated in sulphur forms MgS —6 Heated in nitrogen forms Mg_3N_2 , with phosphorus forms Mg_3P_2 , and with arsenic forms Mg_3As_2 —7 Decomposes carbon monoxide and dioxide, also sulphur dioxide, when heated in these gases, forming MgO —8 Reduces ferric chloride and sulphate solutions to 1eCl, and FeSO_4 (Pfeiffer, *J pr* 61, 441)—9 Reduces nitric acid to HNO_2 (Jenzsch, *N T für Minerale* 1853 535)—10 Reduces carbonates of the alkali metals except Cs, also oxides of copper, silver, and gold, when heated with them in solid form (Winkler, *B* 23, 44), also reduces oxides of Ca, Sr, Ba, Zn, Cd, and Hg (W B 23, 120)—11 Dissolves in dilute acids with formation of salts MgX_2 , X = Cl, $\frac{1}{2}\text{SO}_4$, &c., and evolution of H, or N oxides from HNO_3 . Conc hot H_2SO_4 forms MgSO_4 and SO_2 —12 Dissolves in hydrogen peroxide solution with formation of MgO_2H_2 . From solutions of salts of copper, iron, manganese, and cobalt Mg ppts the metals, with evolution of H, from some metallic salts Mg ppts hydrated oxides, e.g. AlO_2H_2 , from solutions of Al salts, from solutions of salts of arsenic or antimony, Mg evolves AsH_3 or SbH_3 —13 Mg forms alloys with most of the metals (v *Magnesium, alloys of*)

Detection and estimation—Solutions of Mg salts are not pptd by HClAq , $\text{H}_2\text{SO}_4\text{Aq}$, H_2S , or NH_4HS . Fixed alkalis and their carbonates ppt MgO_2H_2 or MgCO_3 , insoluble in excess, but soluble in NH_4 salts, especially in NH_4ClAq , hence Mg salts are not pptd by NH_4Aq in presence of NH_4Cl . $\text{Na}_2\text{HPO}_4\text{Aq}$, added to Mg salt solutions, in presence of NH_4Aq , ppts MgNH_4PO_4 .

Mg is usually estimated by ppn as MgNH_4PO_4 , by addition of NH_4Aq and $\text{Na}_2\text{HPO}_4\text{Aq}$, when strongly heated, the pp is changed to $\text{Mg P}_2\text{O}_7$. For details, and methods of separation of Mg from other metals, *Manuals of Analysis* must be consulted.

Magnesium, alloys of Mg forms alloys with most of the metals. By reason of the easy

oxidation of Mg, the preparation of alloys of this metal is somewhat difficult. They may be prepared by melting the metals in H, also by melting the other metal and rapidly immersing the Mg in it. According to Parkinson (*J pr* 101, 375), Mg forms alloys with the alkali metals, Al, Sb, Bi, Cd, Cu, Au, Pb, Hg, Pt, Ag, Tl, Sn, Zn, also with Cu and Ni together, but not with Co, Fe, or Ni alone. The alloys of Mg are generally very brittle.

Magnesium, aluminate of, MgAl_2O_4 , v ALUMINATES, vol 1 p 141

Magnesium, antimonate of, $\text{Mg}(\text{SbO}_3)_2 \cdot 12\text{H}_2\text{O}$, v ANTIMONATES, vol 1 pp 285, 286

Magnesium, arsenates of, v ARSENATES, vol 1 p 308

Magnesium, arsenide of, Mg_3As_2 . Brown mass. Formed by heating a mixture of As and Mg turnings in H (Parkinson, *J pr* 101, 375, cf ARSENIC, *Combinations* No 9, vol 1 p 303).

Magnesium, arsenites of, v ARSENITES, vol 1 p 306

Magnesium, borates of, v BORATES, vol 1 pp 529, 530

Magnesium, boride of. According to Phipson (*C N* 9, 219), a greenish black mass, which is probably a boride of Mg, is produced by heating Mg with boric acid.

Magnesium, borofluoride of, $\text{Mg}(\text{BF}_4)_2$ (Berzelius, *P* 2, 113), v BOROFLOURIDES, vol 1 p 526

Magnesium, bromide of, MgBr_2 . Mol w unknown, as V D has not been determined. Occurs in small quantity in sea water, and in some mineral springs, also in the Stassfurt salt deposits. Obtained by passing Br vapour over melted Mg. The reaction is very violent (Lerch, *J pr* [2] 28, 338). A white, very deliquescent, fusible, wax like, crystalline mass. By concentrating a solution of MgO in HBrAq , white deliquescent crystals of the hydrated bromide, $\text{MgBr} \cdot 6\text{H}_2\text{O}$, are obtained (Rammelsberg, *P* 55, 239), the same hydrate is formed, along with an insoluble oxybromide, by the reaction between Mg and Br under water (Lerch, 1c). Evaporation of MgBr_2Aq to dryness, or heating the crystals of $\text{MgBr} \cdot 6\text{H}_2\text{O}$, is attended with evolution of HBr and formation of an oxybromide. Heated in a stream of O, MgBr_2 is entirely decomposed to MgO (Schulze, *J pr* [2] 21, 407). Kremers (*P* 108 118) and Gerlach (*Fr* 8, 285) give the following data for S G, and percentage composition, of MgBr_2Aq —

Pct MgBr_2	S G of solution	Pct MgBr_2	S G of solution
5	1 043	30	1 310
10	1 087	35	1 377
15	1 137	40	1 451
20	1 191	45	1 535
25	1 247	50	1 625

The double compounds $\text{MgBr} \cdot \text{KBr} \cdot 6\text{H}_2\text{O}$ and $\text{MgBr}_2 \cdot \text{NH}_4\text{Br} \cdot 6\text{H}_2\text{O}$ are obtained by evaporating mixed solutions of the constituent salts (Lerch, *J pr* [2] 28, 338).

Magnesium, chloride of, MgCl_2 . Mol w unknown, as V D has not been determined.

Occurrence—In sea water and in several mineral springs, also in the salt deposits of Stassfurt.

Formation—1 The mother liquor, after re-

moving KCl from the Stassfurt salts, is evaporated to SG 1375 and allowed to crystallise. The crystals of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ are heated to melting, whereby they are partially dehydrated, but at the same time some oxychloride is formed. By exposing the crystals to a temperature of $c 100^\circ$ under greatly reduced pressure almost pure MgCl_2 is obtained—2 MgCl_2 is obtained as a by-product in Weldon's process for making Cl, and in Solway's soda ammonia process when MgO is used to decompose NH_4Cl —3 By heating MgO with NH_4Cl , adding some NH_4Cl from time to time

Preparation—1 Powdered MgO , or *magnesia alba*, is dissolved in HClAq , NH_4Cl is added in quantity sufficient to prevent pptn of $\text{MgO} \cdot \text{H}_2\text{O}$, on addition of NH_4Aq , the solution is made slightly alkaline by NH_4Aq , any silica which separates is filtered off, the liquid is neutralised by HClAq , and evaporated to dryness. The double salt $\text{NH}_4\text{Cl} \cdot \text{MgCl}_2 \cdot x\text{H}_2\text{O}$ is thus obtained, it is heated to melting ($c 460^\circ$) in a Hessian crucible, in the bottom of which is placed a smaller Pt dish (Bunsen, *A* 82, 137), until NH_4Cl is entirely removed, the MgCl_2 collects in the Pt dish at the bottom of the Hessian crucible (*cf* Doberner, *S* 28, 90)—2 By heating $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ in a current of HCl (Hempel, *B* 21, 897)

The hydrated chloride $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ is obtained by evaporating the solution of MgO in HClAq to the crystallising point

Properties—A white, deliquescent, solid, consisting of a mass of small pearly crystals, SG 2177 (Playfair & Joule, *C S Mem* 2, 401). Can be distilled in H at red heat. Dissolves readily in water with production of much heat, $[\text{MgCl}_2 \cdot \text{Aq}] = 85,920$ (*Th* 3, 243) Thomsen (*lc*) gives the thermal data $[\text{Mg}, \text{Cl}^\circ] = 151,010$, $[\text{Mg}, \text{Cl}^\circ \text{Aq}] = 186,930$. Sol in alcohol, also in amyl alcohol Gerlach (*J* 1859 43) gives the following table—

P ct. MgCl_2	SG $\text{MgCl}_2 \cdot \text{Aq}$	P ct. MgCl_2	SG $\text{MgCl}_2 \cdot \text{Aq}$
1	1.0084	19	1.1686
2	1.0169	20	1.1780
3	1.0253	21	1.1879
4	1.0338	22	1.1977
5	1.0422	23	1.2076
6	1.0510	24	1.2175

14	1.1220	32	1.3012
15	1.1311	33	1.3121
16	1.1404	34	1.3230
17	1.1498	35	1.3340
18	1.1592		

The hydrate $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ crystallises in monoclinic forms, SG 1558 (Fihol, *A Ch* [3] 21, 415) *S* 167 cold water, 367 hot water (Cassacca, *C R* 37, 350) *S* 20 in alcohol 19 SG, 50 in alcohol 817 SG

Reactions—1 When the crystals of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ are heated in air, water is given off and at the same time partial decomposition occurs with evolution of HCl and formation of

oxychlorides—2 MgCl_2 is partly decomposed by much water to MgO and HCl

Combinations—1 With *magnesia* to form oxychlorides (*v* *Magnesium, oxychlorides of*, p 162)—2 With *potassium chloride* to form $\text{MgCl}_2 \cdot \text{KCl} \cdot 6\text{H}_2\text{O}$, occurs native as *carminite*, crystallising in rhombic forms according to Marignac (*C R* 155, 650), in hexagonal forms according to Rammelsberg (*Hand der Krystall Chemie*, 204). The double salt is prepared by mixing solutions of the constituents in the proper ratio, evaporating, and crystallising—3 With *ammonium chloride*, and *calcium chloride*, to form $\text{MgCl}_2 \cdot 11\text{H}_2\text{O} \cdot \text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ (*v* Pfaff & Hantz, *A* 66, 250), and $\text{MgCl}_2 \cdot \text{CaCl}_2 \cdot 12\text{H}_2\text{O}$, respectively—4 With *sodium chloride* to form $\text{MgCl}_2 \cdot \text{NaCl} \cdot \text{H}_2\text{O}$ (Poggiale, *C R* 20, 1180)—5 With *ferrie chloride*, and *chromic chloride*, to form $2\text{MgCl}_2 \cdot \text{Fe}_2\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, and $2\text{MgCl}_2 \cdot \text{Cr}_2\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, respectively (Neumann, *A* 244, 328)—6 With *phosphorus oxychloride* to form $\text{MgCl}_2 \cdot \text{POCl}_3$ ($9\text{MgCl}_2 \cdot 10\text{POCl}_3$ according to Cronander, *B* 4, 753), a deliquescent solid, decomposed by hot water (Casselmann, *A* 98, 223) 7 With *iodine trichloride* to form deliquescent, easily decomposed, crystals of $\text{MgCl}_2 \cdot 2\text{ICl}_3 \cdot 5\text{H}_2\text{O}$, obtained by dissolving $\text{Mg}(\text{IO}_3)_2$ in conc HClAq , leading HCl into the liquid to saturation, and surrounding by a freezing mixture (Fihol, *J Ph* 2, 442)—8 With *ammonia* to form $\text{MgCl}_2 \cdot 4\text{NH}_3$, a white sublimate by heating MgCl_2 in NH_3 (Clark, *A* 78, 369)

Magnesium, chromate of, *v* CHROMATES, vol II p 155

Magnesium, fluoride of MgF_2 . Mol w unknown as VD has not been determined. Occurs native as *sellaite*. Formed by dissolving *magnesia alba* in HF Aq , evaporating to dryness, and heating the residue, also by ppg a Mg salt in solution by a soluble fluoride. Obtained in crystals, either by melting the salt, prepared as described, with NaCl or KCl (Cossa, *Z K* [2] 1, 207), or by melting together 5 parts MgCl_2 , 4 parts NaF, and 4 parts NaCl (Röder). Four sided, very hard, white needles SG 2856 at 12° (Cossa, *B* 10, 295) Guntz (*A Ch* [6] 3, 5) gives the thermal data $[\text{MgO} \cdot \text{H}^\circ; 2\text{HF}] = 28,400$. Forms a double compound with NaF, viz $\text{MgF}_2 \cdot \text{NaF}$. Obtained by adding $\text{MgO} \cdot \text{H}$ to NaFAq and evaporating, the decomposition according to Tissier (*J pr* 90, 50) is

Magnesium, haloid compounds of Mg forms a single compound, MgX_2 , with each of the halogens. None of these compounds has been gasified, hence the molecular weight of none is known with certainty, but the great similarities between Mg, Zn, and Cd, make it extremely probable that the formula MgX_2 expresses the composition of the molecules of the compounds in question MgCl_2 , MgBr_2 , and MgI_2 crystallise with $6\text{H}_2\text{O}$, when these crystals are heated they are partly decomposed to MgO and $\text{HX} (\text{X} = \text{Cl}, \text{Br}, \text{or I})$

Magnesium, hydrosulphide of $\text{MgS} \cdot \text{H}_2$. A solution of this compound is obtained by passing H_2S through MgO suspended in water, the MgO dissolves and leaves a nearly colourless solution, which evolves H_2S when exposed to air or heated. The solution thus prepared contains 16 p c $\text{MgS} \cdot \text{H}_2$, and has SG 1.118 at 15°

(Divers & Shimidzu, *C J* 45, 699) $\text{MgS.H}_2\text{Aq}$ is also formed by treating MgS with water. A solution of MgS.H_2 is a convenient source of H_2S , a steady stream of the gas is obtained by heating to $60^\circ\text{--}65^\circ$ (D & S *lc*). Thomsen gives the thermal data $[\text{Mg}, \text{S}^2, \text{H}^2, \text{Aq}] = 114,880$ (*Th* 3, 243).

Magnesium hydroxide of MgO.H_2 . Occurs native as *brucite*, forming white, pearly, crystalline tablets (hexagonal rhombohedra), SG 2 35 to 2 46. Prepared by ppg a Mg salt by NaOHAq , washing, and drying at 100° , also by direct combination of water with MgO , and drying at 100° , SG 2 36 at 15° (Schulten, *C R* 101, 72). MgO which has been heated to whiteness does not combine with water (*v* Deville, *C R* 61, 975, Knapp, *D P J* 202, 513, Schwarz, *D P J* 186, 25, Ditte, *C R* 73, 111, 191, 270) $[\text{Mg}, \text{O}^2, \text{H}^2] = 217,320$, $[\text{Mg}, \text{O}, \text{H}, \text{O}] = 148,960$ (*Th* 3, 243). Soluble c 100,000 parts water, $\text{MgO.H}_2\text{Aq}$ is feebly alkaline to litmus, with acids MgO.H_2 reacts as a strong base, forming salts MgX_2 , $\text{X} = \text{Cl}, \text{NO}_3, \frac{1}{2}\text{SO}_4, \frac{1}{2}\text{PO}_4$, &c., $[\text{MgO}^+\text{H}^2, \text{H}^2\text{SO}_4\text{Aq}] = 31,220$, $[\text{MgO}^+\text{H}^2, 2\text{HNO}_3\text{Aq}] = 27,520$, $[\text{MgO}^+\text{H}^2, 2\text{HClAq}] = 27,690$ (*Th* 3, 243) (*cf* *Magnesium, oxide of*).

Magnesium iodide of MgI_2 . Mol w unknown as VD has not been determined. Obtained by throwing *I*, in small quantities at a time, on to molten Mg (Lerch, *J pr* [2] 28, 338), reaction is very violent. A white, waxy solid, very deliquescent. A hydrate, $\text{MgI}_2.8\text{H}_2\text{O}$ according to Lerch (*lc*), is formed by the reaction between *I* and Hg under water (*l*), or by dissolving *magnesia alba* in HIAq and evaporating over H_2SO_4 , very deliquescent. MgI_2 is decomposed by heating in air, giving off *I*, and forming MgO , heated in *O* it is entirely changed to MgO (Schulze, *J pr* [2] 21, 407). MgI forms double compounds with *KI* and NH_4I (Lerch, *lc*). The following table is given by Kremers (*P* 108, 118) —

Pc MgI_2	SG MgI_2Aq at 19°	Pc MgI_2	SG MgI_2Aq at 19°
5	1 043	35	1 395
10	1 088	40	1 474
15	1 139	45	1 568
20	1 194	50	1 668
25	1 254	55	1 780
30	1 320	60	1 915

Magnesium nitride of Mg_3N_2 . Mol w unknown, as VD has not been determined. Obtained in small transparent crystals by Deville & Caron in making Mg . Briegleb & Geuther (*A* 123, 236) prepared Mg_3N_2 by heating Mg turnings in a stream of dry pure *N*. Mg_3N_2 is also formed, according to Mallet (*C N* 88, 39), when Mg is heated in a small quantity of air. Prepared by heating Mg in *N*, Mg_3N_2 is an amorphous, greenish yellow, powder, becomes brown on heating. Heated in air it is slowly oxidised to MgO , the oxidation is rapid when *O* is substituted for air. With water, forms MgO and NH_3 . With dilute acids, forms Mg salts and NH_3 salts. Heated in HCl , MgCl_2 and NH_4Cl are formed. Heated in dry H_2S , MgS and $(\text{NH}_4)_2\text{S}$ are slowly formed. Heated to redness in CO or CO_2 , MgO , *C*, and C_2N_2 are produced. PCl_5 vapour reacts to form MgCl_2 and *P* nitride.

VOL. III.

Magnesium, oxide of. MgO (*Magnesia*)

Mol w unknown, as compound has not been gasified. SG 3 642 at 12° (Cossa, *B* 10, 1747), SG crystallised 3 636 (Ebelmen, *J* 4, 15), for SG of MgO heated to temperature from 350° to bright redness *v* Ditte, *C R* 73, 111, 191, 270.

A new medicine was introduced in Rome in the beginning of the eighteenth century, the name *magnesia alba* given to it is supposed to have been suggested as a distinction from *magnesia nigra*, a term then applied to *pyrolustite*, MnO . The preparation of the new medicine was kept secret. In 1709 Slevogt showed that *magnesia alba* could be obtained by ppg the mother liquor from the preparation of saltpetre by K_2CO_3 . *Magnesia alba* was supposed to be the same as lime, but Hoffmann found that some of its reactions differed from those of this compound. In 1755 Black demonstrated *magnesia alba* to be a compound of CO_2 with a new earthy base, to which he gave the name *magnesia*.

Occurrence — MgO occurs as *periclase*, crystallised in regular octahedra, SG 3 67, usually coloured green from presence of a little FeO .

Formation — 1 By adding NaOHAq or KOHAc to solution of a Mg salt, washing, and strongly heating the pp of MgO.H_2 . — 2 By calcining *magnesia alba*, a basic Mg carbonate obtained by ppg a Mg salt by an alkaline carbonate (*v* CARBONATES, vol 1 p 699). — 3 By burning Mg in *O*. — 4 By decomposing MgCl_2Aq by calcined dolomite, $\text{MgCl}_2\text{Aq} + \text{CaO.MgO} = 2\text{MgO} + \text{CaCl}_2\text{Aq}$. — 5 In crystals same as *periclase*, by strongly heating powdered MgO in a slow stream of HCl gas (Dewille, *A* 120, 183), also by heating powdered MgO in a porcelain oven (*H* Rose).

Preparation — 1 A boiling solution of pure $\text{MgSO}_4.7\text{H}_2\text{O}$ is pptd by $\text{Na}_2\text{CO}_3\text{Aq}$, after boiling for a little the pp is washed and dried, and the product $(4\text{MgCO}_3.\text{MgO.H}_2\text{O})$ is calcined in a Pt vessel until every trace of CO_2 and H_2O is removed. — 2 *Magnesia alba* is treated with enough dilute HNO_3Aq to dissolve nearly but not quite all, after standing for some time in the air with frequent stirring, to ppt $\text{Fe}_2\text{O}_3.x\text{H}_2\text{O}$, the liquid is filtered, the filtrate is mixed with a little pure MgSO_4 , alcohol is added, and, after digesting for some time with pure CaSO_4 , the liquid is evaporated to crystallisation, and agar filtered, finally the filtrate is evaporated to dryness, the $\text{Mg}(\text{NO}_3)_2$ thus obtained is calcined, the residue is very thoroughly washed, and again calcined (Wuriz). (For preparation of pure MgO from *magnesite v* Caron, *C R* 66, 840).

Properties — A white powder, more or less flocculent according to the temperature and length of time it has been heated. MgO absorbs water and CO_2 from the air, slowly forming $\text{MgCO}_3.x\text{MgO.H}_2.y\text{H}_2\text{O}$. It is slightly soluble in water, 1 part requires 55,368 cold or hot water for solution according to Fresenius, 100,000 to 200,000 according to Bineau. The solution of MgO is feebly alkaline to litmus. When very strongly heated MgO does not melt but gives out a very clear white light. Made into a paste with a little water, MgO sets to a hard, white mass (Dewille, *C R* 61, 975), MgO which has been heated to whiteness does not set with water (*v* Knapp, *D P J* 202, 513, Schwarz, *D P J* 186, 25). MgO reacts with acids as a strong base.

M

forming salts MgX_2 , $X = Cl, NO_3, \frac{1}{2}SO_4, \frac{1}{2}PO_4$, &c

Reactions—1 With water to form the hydroxide $MgO.H_2$.—2 Heated with ammonium chloride NH_4Cl is evolved and $MgCl_2$ formed.—3 With acids MgO reacts as a strong base forming salts MgX_2 , $X = Cl, \frac{1}{2}SO_4$, &c.—4 With salts of heavy metals MgO reacts similarly to CaO, BaO , and SrO , ppg hydrated oxides.—5 With carbon dioxide and water, basic carbonates $MgCO_3.xMgO.H_2.yH_2O$ are formed.—6 Suspended in water through which is passed a current of hydrogen sulphide, a solution of $MgS.H_2$ is obtained (v *Magnesium, hydrosulphide of*, p 160).—7 Heated in carbon disulphide vapour, MgO MgS is formed (Reichel, *J pr* [2] 12, 55).

Magnesium, oxychlorides of When freshly heated MgO is moistened with $MgCl_2$ Aq, SG 1.16 to 1.26, the whole sets to a firm, hard mass, which probably consists of a mixture of oxychlorides $xMgO.yMgCl_2$ (v *Sorel, C R* 65, 102). By warming 30 parts MgO with 1500 parts $MgCl_2$ in solution, in an atmosphere free from CO_2 , needle shaped crystals slowly form, when washed free from $MgCl_2$, pressed, and dried over soda lime, the crystals are $10MgO.MgCl_2.18H_2O$, dried at 110° they lose $4H_2O$ (Krause, *A* 165, 38).

Magnesium, oxysulphide of $Mg_2OS (= MgO.MgS)$ An amorphous, reddish, solid, obtained, along with COS , by passing CS_2 vapour over heated MgO (Reichel, *J pr* [2] 12, 55).

Magnesium, phosphide of Mg_3P_2 A hard, brittle, steel grey solid, obtained by heating molten P with Mg in H (Parkinson, *C J* [2] 5, 127, 309), or in a sealed glass tube (Emmerling, *B* 12, 152). Decomposed by water, evolving PH_3 , and forming MgO , with acids gives Mg salts and PH_3 .

Magnesium, salts of. Compounds obtained by replacing H of acids by Mg The salts of Mg belong to one series, MgX_2 , where $X = Cl, NO_3, \frac{1}{2}SO_4, \frac{1}{2}CO_3, \frac{1}{2}PO_4$, &c. A few basic salts, and many double salts, of Mg are known. $MgCO_3$, the basic carbonates and phosphates, and a few other salts are insoluble in water, but most of the Mg salts readily dissolve in water. The salts are usually prepared by dissolving $MgO, MgO.H_2$, or $MgCO_3$, in the various acids, and evaporating, some are prepared by double decomposition from the soluble salts, generally from $MgSO_4$. As none of the salts of Mg has been gasified the formulae given are not necessarily molecular, they are based on the results of analysis and considerations of the similarities between the salts of Mg, Zn, and Cd (v **MAGNESIUM GROUP OF ELEMENTS**). The Mg salts are numerous, and as a class very definite and stable bodies, the following are the chief salts derived from oxyacids—bromate, carbonates, chlorate, dithionate, hypochlorite, hypophosphite, iodate, nitrate and -ite, perchlorate, iodates, phosphates and -ite, selenate and -ite, silicates, sulphate and -ite, tellurate and -ite, thiosulphate (v **CARBONATES, NITRATES, SULPHATES**, &c).

Magnesium, selenide of A flesh coloured pp, probably a selenide of Mg, is obtained by adding K_2Se to solution of a Mg salt, the p.p. is decomposed by heat, and by acids, with separation of Se (Berzelius).

Magnesium, silicides of A compound of Mg and Si is prepared by placing a layer of fused and powdered NaCl in the bottom of a Hessian crucible, adding one half of a mixture of $2\frac{1}{2}$ parts NaCl and 7 parts Na_2SiF_6 , then $2\frac{1}{2}$ parts Mg, and then the other half of the mixture of NaCl and Na_2SiF_6 , covering the whole with NaCl, and heating in a wind furnace, when the reaction is completed the contents of the crucible are stirred with a porcelain rod, and allowed to cool. The regulus formed at the bottom of the crucible is a mixture of Mg and Mg silicide, by washing with NH_4Cl Aq the Mg is dissolved out (Geuther, *J pr* 95, 424). As thus prepared the silicide has the composition Mg_2Si . It forms metal like, lustrous crystals. Reacts with HCl Aq to form $MgCl_2, C_2H_4, H_2SiO_3$, and H. This substance may be a compound, or a mixture, of Mg_2Si and $MgSi$ ($Mg_2Si = 2Mg.Si + MgSi$). A silicide Mg_2Si is obtained by pulverising, in a warm mortar, 40 parts fused $MgCl_2$, 35 parts Na_2SiF_6 , 10 parts NaCl, adding 20 parts Na in small pieces, and projecting the mixture into a hot Hessian crucible. After fusion and cooling, the greyish black mass in the crucible is found to contain metal like tablets and globules, these consist of Si and Mg_2Si , by treating with HCl Aq Si remains and SiH_4 is evolved (Wohler, *A* 107, 113, cf *Martius, A* 107, 112).

Magnesium, silicofluoride of $MgSiF_6$, said to be obtained as a gum like, very soluble substance, by dissolving MgO in H_2SiF_6 Aq (Berzelius).

Magnesium, sulphhydrate of, v *Magnesium, hydrosulphide of*, p 160

Magnesium, sulphides of MgS has been isolated, polysulphides, probably MgS_2, MgS_3 , and MgS_4 , seem to exist in the solution obtained by warming MgS with S and H_2O .

MAGNESIUM MONOSULPHIDE, MgS Produced by passing H laden with S vapour over red hot Mg (Reichel, *J pr* [2] 12, 55, cf *Parkinson, C J* [2] 5, 125, 309). According to Fremy, MgS is formed, along with CO , when MgO is strongly heated in dry H_2S , but Reichel (*l.c.*) says that the products of this reaction are MgO, MgS and COS . MgS is also said to be formed, along with $(NH_4)_2S$, by heating $Mg.N_2$ in dry H_2S (Briegleb & Geuther, *A* 123, 236). Fremy (*A Ch* [5] 38, 324) gives $[Mg.S] = 39,800$. MgS is formed, but only in very small quantity, by strongly heating $MgSO_4$ with C. Alkaline sulphides do not ppt MgS , but $MgO.H_2$, from solutions of Mg salts.

MgS , formed by heating Mg and S, is described as a yellowish grey amorphous, or as a reddish brown crystalline mass, analysis always gives rather more S than required by MgS . With water, MgS is decomposed to $MgO.H_2$ and $MgS.H_2$ Aq, the latter being afterwards converted into $MgO.H_2$ and H_2S .

MAGNESIUM POLYSULPHIDES By warming, not boiling, MgS and S with water, a dark yellow solution is obtained, containing Mg and S in a ratio varying from Mg 3S to Mg 5S (Reichel, *J pr* [2] 12, 55). The solution decomposes in air, giving off H_2S and ppg $MgO.H_2$ and S.

Magnesium, sulphocyanide of, $Mg(SCN)_2.4H_2O$, v vol in p 350

M M P M

MAGNESIUM ETHIDE $Mg(C_2H_5)_2$, Magnesium flings act rapidly on ethyl iodide, gas

being given off. If the product be heated in a sealed tube at 125° the contents solidify to a white mass which on distillation gives off MgEt , and leaves a residue of MgI , (Cahours, *A* 114, 227, 354, Hallwachs a Schafarik, *A* 109, 215). These statements are contradicted by Löhr (*A* 161, 48), who finds that EtOAc must be added to the mixture of Mg and EtI , and that the resulting magnesium ethyl is a non volatile solid.

MAGNESIUM GROUP OF ELEMENTS—

Beryllium, Magnesium, Zinc, Cadmium, Mercury Of these five metals, only Zn and Hg are found native, and these in small quantities. Be occurs chiefly as silicate in combination with Al silicate, not widely distributed, Mg salts, especially MgCO_3 and MgSO_4 , are found in large quantities, the chief ores of Zn are ZnCO_3 and ZnS , they occur fairly widely distributed and in considerable quantities, small quantities of CdS and CdCO_3 accompany many Zn ores, the chief ore of Hg is HgS , which is found only in

a few localities. Be is classed with the rare elements, approximately pure Be was not prepared until 1885. Mg was obtained by Davy, in small quantity and impure, in 1800, in 1830 Bussy prepared the metal in a state of approximate purity. Although brass has been made for very many centuries, yet it was not till the middle of the eighteenth century that the art of preparing metallic Zn was known in Europe. Cd was discovered and prepared in 1817 by Stromeyer. Hg has been known certainly from the beginning of the Christian era.

Be and Mg are prepared by reducing the chlorides MCl by Na or K , ZnO and CdO are reduced by heating with C , Hg is prepared from HgS by heating with CaO , whereby CaS and CaSO_4 are formed and Hg is vapourised, or by heating with scrap iron, when FeS , SO_2 , and Hg are produced.

The following table presents some of the prominent physical and chemical properties of the magnesium metals —

	BERYLLIUM	MAGNESIUM	ZINC	CADMIUM	MERCURY
Atomic weights	9.08	24	64.9	111.7	199.8
	One or more compounds of each element, except Mg , have been gasified. Specific heats have been directly determined. Molecular weights of Zn , Cd , and Hg , and probably also of Mg , are the same as the atomic weights.

Sp gr (approx)					
Occurrence and preparation	Double silicate of Be and Al , and a compound of BeO and Al_2O_3 , occur in a few rocks in small quantities. Prepared by reduction of molten BeCl_2 by Na , not by electrolysis of BeCl_2 .	MgCO_3 , MgSO_4 , MgCl_2 , and Mg silicates occur in large quantities and widely distributed. Prepared by reducing molten MgCl_2 by Na , also by electrolysis of MgCl_2 .	ZnO , ZnS , and ZnCO_3 are fairly widely distributed, Zn found native in small quantities. Prepared by reducing ZnO by C at moderately high temperature.	Compounds frequently found accompanying Zn ores. Prepared by reducing CdO by C .	Hg found native in small quantities. Chief ore is HgS , found in a few localities in fair quantity. Prepared by heating HgS in air, or with Fe , or CaO , and condensing Hg .
Physical properties	Steel-coloured, hard, hexagonal crystals, lustrous.	Silver-white, very lustrous, moderately hard, malleable, not very tenacious. Crystallises in hexagonal forms, isomorphous with Zn . Melts at temp much higher than M.P. of Cd or Zn , has not been gasified at white heat.	White, with tinge of blue, crystallises in hexagonal forms, soft; brittle at ordinary temperatures, malleable at 100°–150°, brittle again at 200°. Flexibility varies with temp. Melts at c 430°, can readily be distilled.	White, with slight tinge of blue, crystallises easily in regular forms, soft, but harder than Zn , very malleable, ductile, and flexible. Vapour is yellow. Melts at moderate temperature, c 320°, distils at lower temp than Zn .	Liquid metal at temps above –39°, white, showing faint tinge of blue when compared with Ag , very lustrous. Crystallises in regular octahedra. Boils at c 356°. Volatilises even at very low temperatures.

TABLE—cont

	BERYLLIUM	MAGNESIUM	ZINC	CADMIUM	MERCURY
<i>Chemical properties</i>	Scarcely changed by heating in air or O, burns in O H flame to BeO. Scarcely acted on by S at red heat. Burns in Cl to BeCl ₂ . Dissolves slowly in acids to form salts. Only one series of salts known, BeX ₂ , where X = Cl, $\frac{1}{2}$ SO ₄ , $\frac{1}{2}$ PO ₄ , &c. Dissolves slowly in alkali solutions, evolving H. Distinctly positive metal, does not show alloy tropy, BeO has no acidic properties. Atom of Be is divalent in gaseous molecules.	Unchanged in dry air, heated in air, or O, burns to MgO. Decomposes hot water slowly, burns when heated in steam, forming MgO. Decomposes CO ₂ at red heat. Combines directly with halogens S, P, As, and N. Dissolves in acids to form salts. Only one series of salts is known, MgX ₂ , X = Cl, $\frac{1}{2}$ SO ₄ , &c. MgO.H ₂ is a strong base, compounds of Mg do not show any acidic properties. Valency of atom of Mg not certainly known, as no binary haloid compounds have been gasified. Mol w probably same as at w.	Unchanged in air, heated strongly in air, or O, burns to ZnO. Decomposes steam at red heat. Combines directly with halogens, but not with S. Slowly soluble in alkali solution, with evolution of H. Dissolves in acids to form salts. One series of salts known, ZnX ₂ , X = Cl, &c. ZnO.H ₂ dissolves in alkalis, but is ppt again on evaporation. Over H ₂ SO ₄ <i>in vacuo</i> . There are indications of existence of a hydride of Zn. Atom of Zn is divalent in gaseous molecules. Mol w same as at w.	Slowly oxidised on surface in air, heated in air or O, burns to CdO. Cd vapour and steam heated together form H and CdO. Combines directly with halogens, also with S and P. Dissolves in acids to form salts. Only one series of salts known, CdX ₂ , X = Cl, &c. CdO.H ₂ is not soluble in alkalis. No compound of Cd shows any acidic properties. Atom of Cd is divalent in gaseous molecules. Mol w same as at w.	Unchanged in air, heated nearly to B.P. is slowly oxidised to HgO. Does not decompose water or steam. Combines directly with halogens and S. Dissolves in acids to form salts. Two series of salts* are known, HgX and HgX ₂ , X = Cl, &c., salts of both series are numerous and stable. HgO dissolves in molten KOH to form K ₂ O.2HgO, HgS dissolves in Na or K sulphide solution to form compounds xNa ₂ S.yHgS. Hg forms very many ammonio-compounds. Atom of Hg is monovalent and divalent in gaseous molecules. Mol w same as at w.

General formulæ and character of compounds

Oxides —MO, also in case of Hg, Hg₂O.
 Hydroxides —MO.H₂. Sulphides —MS, also in case of Hg, Hg₂S. Haloid compounds —MX₂, also in case of Hg, HgX. Salts —MX₂, also in case of Hg, MX, X = NO₃, ClO₄, $\frac{1}{2}$ CO₃, $\frac{1}{2}$ SO₄, $\frac{1}{2}$ PO₄, &c.

The oxides MO are basic, they react with acids to form salts MX₂, X = NO₃, $\frac{1}{2}$ SO₄, &c. MgO reacts with water to form MgO.H₂, the other hydroxides MO.H₂ are formed by ppg solutions of salts by alkalis. HgO shows feebly marked acidic properties, it dissolves in molten KOH, and the compound 2HgO.K₂O is obtained on cooling. ZnO.H₂ is sol KOH aq, but is reppd on evaporation *in vacuo* over H₂SO₄. Mercurous oxide Hg₂O is the only representative of the class M₂O, it is very easily resolved into Hg and HgO, it reacts with dilute acids in the cold, as a basic oxide, forming salts HgX. Hg₂O in some respects resembles Cu₂O and Ag₂O, and exhibits the relations of Hg to the copper group (v COPPER GROUP OF ELEMENTS, vol II p 250).

The hydroxides MO.H₂ are all decomposed

by heat to MO and H₂O, HgO.H₂ if it exists is extremely easily separated into its oxide and H₂O, the only hydroxide obtained by direct reaction between MO and H₂O is MgO.H₂. The hydroxides are basic, MgO.H₂ is slightly alkaline.

The sulphides MS are basic. The existence of BeS is extremely doubtful, MgS is readily decomposed by water, giving MgS.H₂Aq, and finally MgO.H₂ and H₂S. ZnS, CdS, and HgS are more stable than MgS, HgS shows slightly acidic properties, it dissolves in K₂SAq or Na₂SAq to form compounds xK₂S.yHgS. Mercurous sulphide Hg₂S is very easily decomposed to HgS and Hg.

The haloid compounds MX₂ may be obtained by the direct union of the elements, the mercurous compounds HgX are also obtained in this way. MX₂ and HgX are also prepared by dissolving the corresponding oxides in HXAq and evaporating, but MgCl₂ cannot be thus obtained, as evaporation towards dryness of MgCl₂Aq results in formation of HCl and MgO mixed with oxychlorides xMgO.yMgCl₂. The compounds

BeCl_2 , BeBr_2 , ZnCl_2 , CdBr_2 , HgCl_2 , HgI_2 , and probably HgCl , have been vapourised without decomposition. The haloid compounds form many double compounds. They all combine with NH_3 , various ammonio derivatives of HgX_2 , and HgX are known. Numerous oxyhaloid compounds, $\text{xMO} \cdot \gamma\text{MX}_2$, are known.

The salts MX_2 are numerous and well marked, they are obtained by dissolving the corresponding oxides or carbonates in acids, and evaporating. Mercurous salts HgX are prepared by digesting excess of Hg with the various acids in the cold. Many basic salts of Be , Zn , and Hg have been prepared, most of the salts of Mg are normal.

The five metals Be , Mg , Zn , Cd and Hg belong to Group II, as the elements are arranged in accordance with the periodic law. The following table shows their positions in the Group —

Even Series				
2	4	6	8	
$\text{Be} = 9$	$\text{Ca} = 40$	$\text{Sr} = 87$	$\text{Ba} = 137$	
Odd Series				
3	5	7	9	11
$\text{Mg} = 24$	$\text{Zn} = 65$	$\text{Cd} = 112$	—	$\text{Hg} = 200$

The properties of Be , the first member of the group, suggest those both of the even and odd series members. Physically it approaches Mg , Zn , and Cd more than Ca , Sr , and Ba , in the conditions under which it is oxidised, the basic but non alkaline character of its hydroxide, the existence of many basic salts, &c. Be shows closer resemblances to Zn , Cd , and Hg than to Ca , Sr , and Ba . The solubility of $\text{BeO} \cdot \text{H}_2$ in KOH aq. also suggests the solubility of $\text{ZnO} \cdot \text{H}_2$ in KOH aq., and of HgO in molten KOH , the hydroxides of Ca , Sr , Ba , and Mg are quite insoluble in alkalis. Mg is closely related in many respects to the metals of the alkaline earths, Ca , Sr , and Ba , but its much greater stability in air, its non decomposition of cold water, the easy resolution of its hydroxide into MgO and H_2O by heat, &c., exhibit the analogies between Mg and Zn , Cd , Hg . Sulphides of Ca , Sr , and Ba are readily formed, but MgS is only produced by heating Mg to redness in H_2 laden with S vapour, the difficulty of forming MgS recalls the non-isolation of any compound of Be and S . Alkali carbonate solutions ppt MCO , from solutions of salts of Ca , Sr , and Ba , but the pps obtained from Mg salts are basic carbonates $\text{xMgCO}_3 \cdot \gamma\text{MgO} \cdot \text{H}_2\text{O}$. The sulphates of Ca , Sr , and Ba are reduced to MS by heating with C , but MgSO_4 is scarcely, if at all, reduced in this way. Hg is distinguished from the other members of the magnesium family by its physical properties, the formation of two series of salts, the formation of a large number of ammonio-derivatives of both series of Hg salts, and in other ways.

In the composition of their salts, and sometimes in the isomorphism of salts, the metals of the Mg family resemble those of the Fe family, viz Mn , Fe , Ni , Co (*v* IRON GROUP OF ELEMENTS, p 65). For a further treatment of the elements of Group II *v* CLASSIFICATION, vol II pp 204-207, *cf* also ALKALINE EARTHS, METALS OF THE, vol I p 112.

M M P M

MAGNETIC ROTATORY POWERS of liquid compounds, *v* PHYSICAL METHODS, section Optical methods.

MAIROGALLOL $\text{C}_{18}\text{H}_{18}\text{Cl}_2\text{O}_{10}$ (?) [190°] (*From malpw*, I glitter). Obtained, together with leucogallol, by passing chlorine through pyrogallol (15 g) dissolved in 60 p.c. acetic acid (45 g) until the liquid is brown, and allowing the liquid to stand (Groves, *A* 179, 237, Stenhouse & Groves, *C J* 28, 706, Webster, *C J* 45, 208). Tri-metric prisms, insol water, *v* sol hot alcohol, extremely sol ether, insol CS_2 , and petroleum ether. Decomposed by boiling with water yielding CO , oxalic acid, and tri-chloro pyrogallol. Reduced by zinc and H_2SO_4 to tri-chloro pyrogallol (Webster, *C J Proc* 3, 130, Hantzsch & Schniter, *B* 20, 2033). Boiling with dilute H_2SO_4 gives a condensation product, and also a substance that is pptd from aqueous solution by gelatin. Aqueous NaHSO_3 and zinc dust reduce it to tri-chloro pyrogallol and an amorphous substance which yields furfuraldehyde when distilled with dilute H_2SO_4 . Mairogallol gives a crimson colour with solution of sodium sulphite (Cross & Bevan, *C J* 43, 18). Mairogallol when gradually heated gives a sublimate of tri-chloro quinone and tetra-chloro quinone. These reactions indicate that mairogallol is derived by condensation from $\text{CO} < \begin{smallmatrix} \text{C}(\text{OH})_2 & \text{C}(\text{OH})_2 \\ \text{CCl} & - & \text{CCl} \end{smallmatrix} > \text{CCl}_2$ (Webster).

MALACHITE GREEN *v* TETRA METHYL-DIAMIDO TRI PHENYL-CARBINOL.

MALAMIC ACID *v* MALEIC ACID.

MALEIC ACID $\text{C}_4\text{H}_2\text{O}_4$, *vc*

$\text{CO}_2\text{H} \cdot \text{CH} \cdot \text{CH} \cdot \text{CO}_2\text{H}$. Mol w 116 (confirmed by Raoult's method, Paternò, *B* 21, 2158) [130°] R_D 38.6 (in a 6.9 p.c. aqueous solution, Kanonnikoff, *J pr* [2] 31, 347, *cf* Knop, *A* 248, 175) H C v 331,702 (Lougounine, *C R* 106, 1290) H C v 326,900 (Stohmann, Kleber & Langbein, *J pr* [2] 40, 217) H C p 326,300 (S K & A) H F 187,700 (S K & A) Heat of solution -4,438 (Gal & Werner, *Bl* [2] 47, 158) Heat of neutralisation 26,648 (G & W).

Formation—1 Together with fumaric acid (*q v*) by the distillation of maleic acid (Lassaigne, *A Ch.* [2] 11, 93, Pelouze, *A Ch.* [2] 56, 72, Liebig, *A* 11, 276, Buchner, *A* 49, 57, Kekulé, *A Suppl* 1, 129, 2, 85, Von Richter, *Z* [2] 5, 453)—2 By heating silver succinate at 180° (Bourgoin, *C R* 72, 52)—3 By saponification of the ether obtained from di-chloro acetic ether by heating with reduced silver at 220°, or by the action of sodium upon its ethereal solution in the cold (Tanatar, *B* 12, 1563)—4 By the action of KCN on α -di-bromo propionic acid (Tanatar, *B* 13, 159)—5 From δ -bromo pyromucic acid and dilute HNO_3 (Hill & Sanger, *A* 232, 55)—6 By the action of baryta on tri-chloro phenomalic acid ($\begin{smallmatrix} \text{CH} & \text{C}(\text{OH}) & \text{CCl}_2 \\ || & & \\ \text{CH} & \text{CO} & \end{smallmatrix}$).

Preparation—Maleic acid is rapidly distilled until the residue thickens, the flame being then withdrawn, the distillation then continues by itself until the residue is solid (fumaric acid). The distillate consists of maleic acid and maleic anhydride, and may be wholly converted into maleic anhydride by AcCl . The maleic anhydride may be purified by crystallisation from

HOAc and then converted by hot water into maleic acid (Anschutz, *B* 12, 2281, cf Perkin, *B* 14, 2547)

Properties—Monoclinic prisms ∇ sol water and alcohol, m sol ether. Its aqueous solution reddens litmus strongly. Begins to boil at 160°, being then restored into maleic anhydride and water, which partially re unite in the receiver. An aqueous solution of maleic acid is ppd by baryta (difference from fumaric acid). Unlike fumaric acid, maleic acid is not ppd by adding mineral acids to solutions of its salts.

Reactions—1 Reduced by water and sodium amalgam to succinic acid. Zinc added to an aqueous solution of maleic acid yields zinc maleate and succinate. 2 Calcium maleate fermented in contact with cheese also changes to succinate (Dessaignes). 3 *Electrolysis* gives acetylene, succinic acid, and a small quantity of fumaric acid (Kekulé, *A* 180, 1). 4 Combines readily with bromine in the cold, forming iso dibromo succinic acid and some di bromo succinic acid derived from fumaric acid into which a portion of the maleic acid is at the same time transformed (Kekulé, Petri, *A* 195, 59). *Chlorine* gives a di chloro succinic acid (Petrifff, *Bl* [2] 41, 309). Bromine in presence of water forms iso di-bromo-succinic, bromo fumaric, bromo succinic, and fumaric acids (Wilschusen, *A* 246, 58). 5 Dissolves easily in aqueous HBr, the solution even at 0° soon depositing fumaric acid and bromo succinic acid in equimolecular proportions. The bromo succinic acid may easily be extracted from the product by water (Fittig & Dorn, *B* 9, 1191). 6 Converted into fumaric acid by boiling conc HIAq, HBrAq, dilute HNO₃, or HClAq (Kekulé, *A* Suppl 1, 184, 2, 93, Kekulé a Strecker, *A* 223, 186). When HIAq is used the ultimate product is succinic acid. Dry HCl does not convert maleic acid into fumaric. Maleic acid is converted into fumaric acid by heating its aqueous solution at 100°–180° (Semenoff, *Bl* [2] 46, 816). An aqueous solution of sodium maleate is not affected by being heated for 10 hours in a sealed tube at 100° to 185°. 7 With hypochlorous acid it forms a compound which reduced by sodium amalgam yields inactive malic acid, oxymaleic acid (?), and a liquid which breaks up on heating into CO₂ and C₆H₁₀O₆ (Petrifff). 8 KMnO₄ oxidises it to inactive tartaric acid. 9 Alcoholic NH₃ at 150° slowly forms aspartic acid (Engel, *C R* 104, 1805). 10 The acids of the *maleic series* readily split off H₂O from their acid aniline salts, when the aqueous solution of the latter is left to stand for several days or boiled, a crystalline pp being formed of the acid anilide $X'' < \begin{smallmatrix} \text{CONHPh} \\ \text{CO}_2\text{H} \end{smallmatrix}$ or of

an isomeride thereof. Under the same conditions the acid aniline salts of the acids of the *fumaric series* are quite stable. This constitutes a ready method of determining to which of the two isomeric series a given acid belongs. The acid is half neutralised with aniline and either left to stand or heated to boiling, if a pp is obtained insoluble in dilute HCl the acid belongs to the *maleic series* (Michael, *B* 19, 1872).

Salts—K₂A'' (dried at 100°). Radiating crystals, ∇ sol water, insol alcohol. —KHA'' $\frac{1}{2}$ aq small crystals, ∇ sol water. The solution reddens litmus. —Na₂A'' needles. Ppd as a

granular crystalline powder by adding alcohol to its aqueous solution. Is not deliquescent. —NaHA'' $\frac{3}{4}$ aq Trichinic crystals (Bodewig, *J* 1881, 716). Sl sol cold water. —KNaA'' aq deliquescent crystalline powder (Büchner, *A* 49, 60). —BaA'' $\frac{2}{3}$ aq gelatinous pp, changing to scales *S* 11 at 20° (Regnault). —BaA'' aq (Anschutz) —BaH₂A'' $\frac{5}{6}$ aq indistinct crystals, which redden litmus, ∇ sol water (Büchner). —CaA'' aq (dried at 100°) small needles, sol water. —CaH₂A'' $\frac{5}{6}$ aq long prisms, ∇ sol water, insol alcohol. —SrA'' $\frac{5}{6}$ aq silky needles. —SrH₂A'' $\frac{8}{9}$ aq rect angular prisms. —MgA'' $\frac{3}{4}$ aq —MgH₂A'' $\frac{6}{7}$ aq hard crystals, ∇ sol water, insol alcohol. —ZnA'' $\frac{2}{3}$ aq crystals, ∇ sol water, insol alcohol. —NiA'' aq apple green crystals. —CuA'' light blue crystals, sl sol boiling water, ∇ sol NH₃Aq, forming a solution whence alcohol ppts an azure blue crystalline powder. —PbA'' $\frac{3}{4}$ aq amorphous pp, changing to needles. —Pb₂A''O (dried at 100°, Otto, *A* 127, 178). —AgA'' white pp, changing to lustrous needles. —AgHA'' (dried at 100°) needles.

Acid aniline salt C₆H₅NH₃HA'' $\frac{1}{2}$ aq prisms, sol water. On allowing the solution to stand for some days it forms phenyl aspartic acid C₆H₅NH C₆H₄(CO₂H)₂ [132°] (Anschutz a Wirtz, *A* 239, 140, cf Michael, *B* 19, 1373, *Am* 9, 333, 197). The neutral aniline maleate when boiled in aqueous solution deposits the phenylimide of phenyl aspartic acid C₆H₅NH C₆H₄ < $\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}$ > NC₆H₅, a body [212°] which was formerly described as the di anilide of maleic acid C₆H₄(CONHPh)₂.

Phenyl-imide C₆H₅ < $\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}$ > NC₆H₅ [91°] (162° at 12 mm). Formed by the dry distillation of acid aniline maleate (Anschutz a Wirtz, *Am* 9, 238, cf Michael a Wing, *Am* 7, 280). Long yellow needles, ∇ sol benzene, CHCl₃, ether, and alcohol, sl sol CS₂, and ligrom. Its solution in chloroform takes up bromine, forming the phenyl imide of di bromo succinic acid [159°]. Baryta water at 40° gives the acid anilide of fumaric acid.

Mono methyl ether HMeA'' Probably exists in the solution of maleic anhydride in MeOH. Such a solution becomes hot when mixed with NaOMe, probably forming NaMeA'', but the solution presently deposits a bulky white, partly crystalline, pp, which forms an alkaline aqueous solution, becoming neutral on boiling, the neutral solution contains the methyl derivative of sodium methyl maleate

C₆H₅(OMe)(CO₂Na)(CO₂Me) (Purdie, *C J* 47, 873)

Di methyl ether Me₂A'' (205° i ∇) *S G* 14 1158 H C 669,570 (Ossipoff, *C R* 109, 312). From silver maleate and MeI, excess of iodine being avoided, as this would convert it into di methyl fumarate (Anschutz, *B* 12, 2282). Bromine effects the same change.

Mono-ethyl ether HEtA'' From the anhydride and boiling alcohol. Also from HAgA' and EtI (Ossipoff, *J R* 20, 254). Not identical with the mono ethyl ether of fumaric acid. Forms a salt NaEtA'' By treating HEtA'' with NaOEt and boiling the product with water C₆H₅(OEt)(CO₂Et)(CO₂Na) is obtained, identical with that derived from fumaric acid (Purdie)

Di-ethyl ether Et₂A" (225° i V) From Ag₂A" and EtI (Anschütz, *B* 11, 1644, 12, 2281) Vapour density corresponds to the formula (O) Colourless liquid Converted by iodine into the fumaric ether Bromine gives di bromo succinic ether Boiling with NaOMe forms a product whence boiling water produces C₂H₃(OMe)(CO₂Et), (Purdie, *C J* 47, 868)

Di-isopropyl ether Pr₂A" Vapour density corresponds to the formula

(Anschütz), [57°] (Pelouze, *A Ch* [2] 56, 72), [60°] (Fittig, *A* 188, 87) (202° i V) (A) V D 48 (H=1) (calc 49) (Hubner & Schreiber, *Z* [2] 7, 712) H C 336,920 (Ossipoff, *C R* 109, 311) Appears to be the sole anhydride of both maleic acid and fumaric acids

Formation—1 By rapidly distilling maleic or fumaric acid, and frequently rectifying the product (Pelouze, *A* 11, 263, Kekulé, *A Suppl* 2, 87) *In vacuo*, maleic acid splits up into water and anhydride even at 100° (Reicher, *R T C* 2, 312) —2 By heating fumaric acid with AcCl and HOAc at 100° —3 From silver fumarate and fumaryl chloride (Perkin, *B* 14, 2645) —4 By distilling chloro or bromo succinic anhydride (Anschütz & Bennert, *B* 15, 643) —5 By distilling maleic anhydride

Preparation—1 Maleic acid is treated with an excess of acetyl chloride, and the product (which probably chiefly consists of acetyl maleic anhydride) is distilled, when it splits up into acetic acid and maleic anhydride, the yield is 45 p c (Perkin, *C J* 39, 562, *B* 14, 2547) —2 By dry distillation of maleic acid and treatment of the residue and distillate with AcCl, the yield is 56 p c of the theoretical (Anschütz, *B* 12, 2281)

Properties—Trimetric crystals, *abc* = 6408 1 4807 (Bodewig, *B* 14, 2788) In contact with water it is converted into maleic acid, which is conveniently prepared in this way The abnormal rapidity of the etherification of maleic acid by heating with alcohols appears to be due to an intermediate formation of anhydride (Reicher, *R T C* 2, 308) Maleic anhydride heated in a sealed tube at 260° gives a carbonaceous residue and gases (Semenoff, *Bl* [2] 46, 816)

Reactions—1 Unites with bromine at 100°, forming iso-di bromo succinic anhydride, which is resolved at 180° into HBr and bromo maleic anhydride —2 PCl₅ gives the chloride of fumaric acid (Perkin, *B* 14, 2648), but maleyl chloride (71° at 11 mm) appears to be first formed (Anschütz & Wirtz) —3 With a saturated solution of HCl in HOAc it forms at 100° chloro-succinic acid —4 When heated with phenylhydrazine (1 mol) at 150° it forms the phenyl hydrazide C₆H₅·C₂O₂·N₂·HPh, which crystallises in needles [259°], and turns brown at 180° (Hötte, *J pr* [2] 35, 295) —5 When heated with phenols it produces fluorescent compounds analogous to the phthaleins, which may therefore be called 'maleins' The resorcin malein has a green fluorescence, (a) naphthol malein has a greenish-red fluorescence (Burckhardt, *B* 18, 2864)

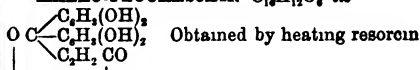

Constitution—The constitution of fumaric

and maleic acids is discussed under FUMARIC ACID, vol ii p 585 The anomalous formula CO₂H C CH₂ CO₂H for maleic acid, based on the formula CO₂H CBr CH₂ CO₂H, is rendered improbable by the observation that bromo-fumaric and not pyruvic acid is the product formed, together with CO₂, when barium iso-di bromo succinate is treated with moist Ag₂O in the dark (Demuth & V Meyer, *B* 21, 264) Racemic acid is formed when silver iso-di bromo succinate is boiled with water The representation of maleic and fumaric acids by formulae in space has been discussed by Wislizenus in his treatise *Ueber die räumliche Anordnung der Atome in organischen Moleculen*

MALIC ACID C₄H₄O₄, s.s

CO₂H CH₂ CH(OH) CO₂H Mol w 134 [100°] S G 2 156 (Schröder, *B* 12, 1611) S G of solutions (Schneider, *A* 207, 262) *Heat of solution*—3148 *Heat of neutralisation* 24,919 (Gal & Werner, *Bl* [2] 46, 803) [α]_D = -3 in dilute solutions, as the liquid becomes more concentrated it approaches +5.9

Occurrence—Maleic acid was discovered by Scheele in 1785, but its composition was first correctly determined by Liebig (*A* 26, 166) It is very widely diffused in the vegetable kingdom, being contained in plants sometimes in the free state, sometimes in the form of potassium, calcium, or magnesium salt It is found in abundance, together with citric acid, in unripe apples, in the fruits of the barberry, sloe, elder, and mountain ash, and in gooseberries, cherries, bilberries, strawberries, raspberries, and many other fruits It is likewise found in the roots of marsh mallow, angelica, aristolochia, bryony, liquorice, primrose, and madder, in carrots and potatoes, in the leaves and stems of aconite, belladonna, hemp, celandine, holy thistle, lettuce, tobacco, poppy, rue, sage, house-leek, tansy, thyme, valerian, and melilot, in the flowers of chamomile, elder, and mullein, in pine apples and grapes, in the seeds of caraway, cummin, parsley, anise, flax, and pepper, in asafetida, opoponax, and myrrh It also occurs in the leaves of the common ash (Gintl, *Z* [2] 5, 377), and in the fruit of the sumach (Reinsch, *Z* 1866, 221) Yolk, the sweat of sheep, contains potassium malate to the extent of 2.5 p c. of the solid residue (Buisine, *C R* 106, 1426)

Formation—1. Maleic acid, with the same

optical properties as those with which it exists in plants, may be formed from asparagine or active aspartic acid by treatment with nitrous acid (Piria, *A Ch* [3] 22, 160)—2 Malic acid, with a rotatory power equal and opposite to that contained in plants, may be obtained from ordinary tartaric acid by the action of phosphorus, iodine, and water (Dessaignes, *A* 117, 134, Bremer, *Bl* [2] 25, 6, *B* 8, 861, 1594)

Preparation—1 The juice of mountain-ash berries, not quite ripe, after being pressed, boiled up, and filtered, is partly neutralised with carbonate of potassium, leaving, however, a sufficient excess of acid to redden litmus pretty strongly, then precipitated by nitrate of lead, set aside for a few days, till the curdy precipitate is completely converted into small needles, these crystals freed from the admixed mucous or flocculent compound of lead oxide and colouring matter by careful elutriation with cold water, are, lastly, well washed with water. The needles of impure malate of lead are boiled with a slight excess of dilute sulphuric acid, the filtrate divided into two equal portions, one portion exactly neutralised with ammonia, the other portion then added, and the reddish liquid evaporated and cooled, it then yields nearly colourless crystals of acid malate of ammonia, which may be rendered quite colourless by recrystallisation. These crystals are then precipitated by acetate of lead, and the precipitate, after thorough washing, is decomposed by sulphydric or sulphuric acid (Liebig)—2 The juice is boiled for some time with milk of lime in quantity not quite sufficient for neutralisation, and the pp poured into a boiling mixture of HNO_3 (1 pt) and water (10 pts) The acid calcium malate which crystallises out on cooling is recrystallised from water, dissolved in water, ppd by lead acetate, and the lead malate decomposed by H_2S (Liebig, *A* 38, 259) By similar processes malic acid may be obtained from house-leek, from cherries or barberries, from the berries of *Rhus coriaria*, from the stems of rhubarb, from apples, and from tobacco

Properties—The aqueous solution, concentrated to a syrup and left to evaporate in a warm place, yields groups of colourless shining needles or prisms of 4 or 6 faces. They melt at 83° (Pelouze) or 100° (Pasteur), and do not suffer any loss of weight at 120° . They deliquesce in the air, and are very soluble in water and alcohol. Dilute solutions of malic acid are laevorotatory, but the rotation changes so rapidly with concentration that concentrated solutions are dextrorotatory. These dextrorotatory solutions are rendered laevorotatory by the addition of H_2SO_4 , or of HOAc $[\alpha]_D = 5.891 - 0.895q$ (where q = percentage of water in solution) (Schneider, *A* 207, 263). Solutions of sodium malate containing about 54 pts of the salt to 46 pts of water are inactive at 20° , stronger solutions are laevorotatory, while more dilute solutions are dextrorotatory (Thomsen, *J pr* [2] 35, 153). Malic acid kills algae (*Zygnemaceae*) (Loew & Bokorny, *J pr* [2] 36, 272). Malic acid prevents the ppn. of cupric and ferric salts by alkalis, 2 mols holding 1 mol of CuO in solution (Hofmeister, *A* 189, 27, cf Juette, *Fr* 7, 489). A dilute solution of malic acid or of a malate is not immediately ppd. by lime water or by CaCl_2 either in

the cold or on heating, but on the addition of alcohol a white pp of calcium malate separates (Braconnot, *A Ch* [2] 51, 331, H Rose, *P* 31, 210). However, a solution of malic acid (1 mol) mixed with pure milk of lime (2 mols) may solidify to a pasty mass (Iwig & Hecht, *A* 238, 171). A concentrated solution of an alkaline malate is ppd by CaCl_2 , but presence of NH_4Cl hinders the ppn, which, however, takes place on adding alcohol. Lead acetate gives a white pp, soluble in excess of malic acid and in ammonia, when the pp is heated in the mother liquid it melts to a semifluid translucent mass. Malates are not blackened by heating with fuming H_2SO_4 . Dilute HOAc at 60° dissolves lead malate, but not lead tartrate or citrate (Hartsen, *Fr* 14, 373, *Ar Ph* [3] 6, 11v). Malic acid may be separated from oxalic and tartaric acids by ppg the latter with CaCl_2 , filtering, and ppg calcium malate by adding alcohol to the filtrate (Barfoed, *Fr* 7, 403). Ammonium malate may be separated from ammonium citrate, tartrate, and oxalate by solution in alcohol (Barfoed)

Reactions—1 Heated for some hours at 140° it yields water and fumaric acid. At 180° it gives off water and maleic anhydride, while fumaric acid remains as a solid residue. If the malic acid be suddenly heated to 200° and kept at that temperature a comparatively large quantity of maleic anhydride is obtained. The maleic anhydride, combining with the water in the distillate, is partially converted into maleic acid. Malic acid is carbonised when suddenly exposed to a red heat—2 By treatment with potash and bromine, bromoform is obtained (Cahours, *A Ch* [3] 19, 507)—3 Nitric acid easily oxidises it to oxalic acid and CO_2 —4 Conc HIAq at 180° reduces it to succinic acid (Schmitt, *A* 114, 106). Succinic acid is also formed when calcium malate is fermented in contact with yeast (Piria, *A* 70, 102, Liebig, *A* 70, 104, 363). Fermentation of calcium malate by certain *Schizomycetes* produces succinic, acetic, butyric, and propionic acids and ethyl alcohol (Fitz, *B* 11, 1896, 12, 481, cf Dessaignes, *C R* 28, 16, Liebig, *A* 70, 104, 363, Kohl, *A* 78, 252, Baer, *Ar Ph* [2] 69, 147, Winkler, *Jahrb pr Pharm* 22, 300, Rebling, *Ar Ph* [2] 67, 300, Béchamp, *C R* 70, 999)—5 By slow oxidation in the cold with $\text{K}_2\text{Cr}_2\text{O}_7$ it is converted into malonic acid (Dessaignes, *A* 107, 251)—6 When boiled in dilute aqueous solution with MnO_2 it yields a distillate containing aldehyde (Liebig, *A* 113, 14)—7 Heated with KOH it yields acetic and oxalic acid—8 When calcium malate (1 pt) is heated with PCl_5 (4 pts) the chloride of fumaric acid passes over (Perkin & Duppa, *A* 112, 24, Liébs Bodart, *A* 100, 327)—9 Boiling aqueous H_2SO_4 at 135° gives aldehyde, CO_2 , water, and CO (Weith, *B* 10, 1744)—10 The electrolysis of potassium malate gives aldehyde, CO_2 , and some acetic acid (Bourgois, *Bl* [2] 9, 427)—11 Water containing a few drops of H_2SO_4 at 160° gives fumaric acid (Markownikoff, *A* 182, 351)—12 When heated with phenol and H_2SO_4 it gives

CO and C_2H_4 $\begin{array}{c} \text{O} - \text{CO} \\ \diagup \quad \diagdown \\ \text{CH} \quad \text{CH} \end{array}$ (Pechmann, *B* 17, 929, 1649)—13 Long boiling with conc HClAq gives fumaric acid—14 Conc HBr at 100° gives bromo-succinic acid and fumaric acid (Kekulé,

A. 180, 11) —15 Chloral at 125° forms
 $\text{CCl}_3\text{CH} \begin{array}{l} \diagup \text{O CH CH}_2\text{CO}_2\text{H} \\ \diagdown \text{O CO} \end{array}$ [140°] This forms

large crystals, sl sol cold water (Wallach, A 193, 42) With PCl_5 it gives the oily chloride $\text{C}_4\text{H}_5\text{Cl}_5\text{O}_2$, whence alcohol forms $\text{C}_4\text{H}_5\text{Cl}_4(\text{OEt})\text{O}_2$ [46°], and MeOH gives $\text{C}_4\text{H}_5\text{Cl}_4(\text{OMe})\text{O}_2$ [85°] — 16 Phenyl hydrazine at 120° forms $\text{C}_{16}\text{H}_{18}\text{N}_4\text{O}_8$, & $\text{C}_2\text{H}_5\text{O}(\text{CO N}_2\text{H}_5\text{Ph})_2$ [223°], which crystallises from dilute alcohol in plates (Bulow, A 236, 195, cf Fischer a Passmore, B 22, 2734) — 17 Malic acid (3 pis) heated with *m* amido-benzoic acid at 150° forms a product whence by washing with hot water and alcohol, dissolving in aqueous NH_3 and ppg by HCl , there is obtained a white powder $\text{C}_8\text{H}_8\text{O}(\text{CO NH C}_6\text{H}_4\text{CO}_2\text{H})_2$. The ammonium salt of this acid forms with cupric acetate a pp of $\text{Cu}(\text{C}_8\text{H}_8\text{N}_2\text{O}_8)_2$. Ac_2O decomposes it, forming NH_4Ac , $\text{C}_6\text{H}_4\text{CO}_2\text{H}$ (Schiff, G 16, 28, A 232, 166)

Salts—Malic acid has a tendency to form acid salts. At 200° the salts give off water and are converted into fumarates— $\text{NH}_4\text{HA}''$ transparent trimetric prisms. Not hemihedral, but becomes so after fusion and recrystallisation SG 125 155 μ S 32 at 157° [α] = -6° On dry distillation it forms fumarimide, fumaric, and maleic acids, and active and inactive malic acid. Combines with acid ammonium tartrate. Normal ammonium malate $(\text{NH}_4)_2\text{A}''$ is v e sol water, and its solution gives off NH_3 to the air, becoming acid. In a solution containing 63 p.c. of the salt [α]_D = -4.2 In a 17 p.c. solution [α]_D = -7.2 (Schneider, A 207, 276) — KHA'' crystals. Begins to decompose at 100° Sol water, insol alcohol [α]_D = -5 in a 21 p.c. solution, = -5.7 in a 9.4 p.c. solution at 20° — KA'' Uncrystallisable and deliquescent mass [α]_D = -2.2 in a 62 p.c. solution, = -6.8 in a 9.4 p.c. solution at 20° (Schneider) — NaA'' Uncrystallisable [α]_D = +4.7 in a 65.5 p.c. solution, = -8.4 in a 5.3 p.c. solution — LiHA'' Uncrystallisable [α]_D = -4.6 in a 50 p.c. solution, = -8.4 in a 10 p.c. solution — $\text{Li}_2\text{A}''$ Uncrystallisable [α]_D = -4.1 in a 39 p.c. solution, = -12 in a 6 p.c. solution at 20° (Schneider, A 207, 273) — BaA'' aq thin plates [α]_D = +8.2 in a 9.4 p.c. solution, = -2.6 in a 2 p.c. solution at 20° — $\text{BaH}_2\text{A}''_2$ Uncrystallisable and more soluble than the neutral salt — SrA'' aq (dried at 100°) Crystalline mass, v sol water — $\text{SrH}_2\text{A}''$ Crystalline pp formed by adding malic acid to a solution of the preceding Sl sol cold, m sol hot, water — CaA'' 3aq S 839 at 15°, 711 at 45°, 566 at 58°, 600 at 65°, 663 at 72°, 737 at 86° (Iwig a Hecht, A 233, 170) Granular crystalline mass. When a solution of malic acid is added to lime water a pasty mass of $\text{A}''\text{Ca}_2(\text{OH})_2$ 9aq (?) is first formed, but when the theoretical quantity of malic acid has been added this dissolves up again, and the clear liquid deposits nodules of CaA'' 3aq in the course of 24 hours — $\text{CaH}_2\text{A}''$ 6aq (Hagen, A 38, 263) Occurs in stems of *Geranium zonale*, the berries of *Rhus glabra* (Rogers, Am S 27, 294), and in tobacco. Separates in well formed trimetric

octahedra from a solution of the neutral salt in warm dilute nitric acid S (of $\text{CaH}_2\text{A}''$) 1287 at 15°, 8514 at 45°, 32236 at 57°, 13127 at 68°, 7437 at 78° (I a H) [α]_D = +5 (Bremer, R T C 3, 164) When the solution obtained by neutralising malic acid with CaCO_3 is boiled a nearly insoluble granular pp is got, which consists of CaA'' aq (Richardson a Meundorf, A 26, 135), or of CaA'' (Hagen, A 38, 257) — MgA'' 6aq Prisms, which separate from a highly concentrated solution (Liebig, A 5, 148) Alcohol ppts MgA'' — $\text{MgH}_2\text{A}''$ 4aq (or 3aq) Flattened prisms — ZnA'' 3aq Monoclinic crystals (Handl, J 1859, 289) Slowly deposited in the cold from the product of solution of zinc carbonate in aqueous malic acid at 30° When these substances are boiled together a basic salt $\text{ZnO}(\text{ZnA}'')_2$ 4aq is deposited as a jelly, changing to a sandy powder, while the filtrate deposits ZnA'' 3aq as hard, four sided prisms S 17 at 20° — $\text{ZnH}_2\text{A}''$ 2aq Elongated octahedra S 4 in the cold — The neutral manganese salt is very soluble and uncrystallisable, by adding malic acid to its solution the acid salt is p.p.d. as a white powder, S 25 From boiling water it separates in rose coloured crystals — The neutral and acid ferric salts are gummy masses, v sol water and alcohol — CuA'' aq green gummy mass, v sol water — $\text{CuH}_2\text{A}''$ 2aq blue crystals, obtained by evaporation at 40° — $\text{CuO}(\text{CuA}'')_2$ 4aq green insoluble powder obtained by boiling aqueous malic acid with cupric carbonate. If evaporated at 45° dark green crystals of $\text{CuO}(\text{CuA}'')_2$ 6aq may be got H Schulze (Ar Ph [2] 57, 273) obtained green crystals of a double salt of cupric malate and ammonium sulphate — PbA'' 3aq Obtained by ppg neutral lead acetate with a solution of calcium or potassium malate, as a white curdy pp, which slowly changes to radiating four sided needles. Melts in boiling water V sl sol cold, m sol boiling, water, from which it is deposited in needles. Dissolves easily in nitric acid, acetic and malic acids do not dissolve it more readily than water. When dry it does not melt at 170° but at 220° it forms lead fumarate — PbA'' aq (dried at 100°) (Otto, A 127, 175) — $\text{PbO}(\text{PbA}')$ — Obtained by digesting the neutral salt with ammonia, or by dropping a solution of a neutral malate into a boiling solution of lead subacetate. Amorphous pp, not becoming crystalline. Does not melt under water. Melts under hot dilute HOAc , evidently changing to the neutral salt. Nearly insol water, to which, however, it imparts an alkaline reaction — AgA'' White granular pp, formed by adding silver nitrate to a solution of neutral or acid ammonium malate — Aniline malate $\text{C}_6\text{H}_5\text{NH}_2\text{HA}''$ [144°] White prisms (from alcohol) On dry distillation it gives water, aniline, the phenyl imide of phenyl aspartic acid [211°], and the phenyl-imide of maleic acid [91°] (Anschutz a Wirtz, Am 9, 237, A 239, 140)

Acetyl derivative $\text{C}_4\text{H}_5(\text{OAc})(\text{CO}_2\text{H})$, [132°] From the acetyl derivative of the anhydride and water (Anschutz, A 254, 165)

Di-methyl ether $\text{Me}_2\text{A}''$ (122 at 10 mm)

Δ g $\frac{24.6}{24.6}$ 12386 Formed, together with MeHA'' , by passing HCl into a cooled solution of malic acid in MeOH (Demondésir, A 80, 301; C. R

23, 227, Anschütz, *B* 14, 2790, 18, 1953) — $\text{Ca}(\text{MeA})_2$, is sol alcohol

Acetyl derivative of the di methyl ether $\text{C}_2\text{H}_5(\text{OAc})(\text{CO}_2\text{Me})_2$ (129° at 11 mm)

From the ether and AcCl

Di-ethyl ether Et₂A (128° at 10 mm)

Formed in like manner Can only be distilled *in vacuo* — $\text{Ca}(\text{EtA})_2$, is sol alcohol

Acetyl derivative of the di ethylether $\text{C}_2\text{H}_5(\text{OAc})(\text{CO}_2\text{Et})_2$ (137° at 12 mm)

Nitroxyl derivative of the di-ethyl ether $\text{C}_2\text{H}_5(\text{ONO})(\text{CO}_2\text{Et})_2$ SG 1^a 202 From the ether, fuming HNO_3 , and conc H_2SO_4 (Henry, *B* 3, 532) Thick oil

Di-n-propyl ether $\text{C}_2\text{H}_5(\text{OH})(\text{CO}_2\text{Pr})_2$ (151° at 10 mm) (Anschutz)

Acetyl derivative of the di-n propyl ether $\text{C}_2\text{H}_5(\text{OAc})(\text{CO}_2\text{Pr})_2$ (157° at 12 mm)

Mono isoamyl ether $\text{C}_2\text{H}_5(\text{OH})(\text{CO}_2\text{H})(\text{CO}_2\text{C}_4\text{H}_9)$ From malic acid and isoamyl alcohol at 120° (Breunlin, *A* 91, 323) — NH_4A needles — CaA , aq plates

Acetyl derivative of the anhydride $\text{CH}(\text{OAc})\text{CO} \begin{array}{l} | \\ \text{CH}_2 - \text{CO} \end{array} \text{O}$ (54°) (161° at 14 mm)

Formed, together with maleic anhydride, by heating malic acid with AcCl (Anschutz, *B* 14, 2791) Decomposed by distillation under atmospheric pressure into HOAc and maleic anhydride

Amide $\text{C}_2\text{H}_5(\text{OH})(\text{CONH}_2)_2$ **Malamide** When gaseous NH_3 is passed into an alcoholic solution of malic ether crystals of malamide are deposited Separates from water in well defined crystals Resolved by hydrolysis into NH_3 and malic acid

Amic ether $\text{C}_2\text{H}_5(\text{OH})(\text{CO}_2\text{Et})(\text{CONH}_2)$ **Malamic ether** Formed as a crystalline mass when gaseous NH_3 is passed into malic ether (Pasteur, *J* 1853, 411)

Di-anilide $\text{C}_2\text{H}_5(\text{OH})(\text{CONHPh})_2$ [175°] Formed, together with the phenyl imide, by boiling aniline (2 mols) with malic acid (1½ mols) The phenyl imide is extracted by boiling water, and the residue recrystallised from alcohol, using animal charcoal (Arppe, *A* 96, 106) Colourless scales Nearly insol water, dilute acids, and alkalis

Mono-anilide $\text{C}_2\text{H}_5(\text{OH})(\text{CO}_2\text{H})(\text{CONHPh})$ **Malamic acid** [145°] Obtained by boiling the phenyl-imide with aqueous ammonia, the product is ppd by baryta, and the Ba salt decomposed by H_2SO_4 , avoiding any excess White granules composed of very minute needles (from alcohol), ν sol water, m sol alcohol, sl sol ether Reddens litmus Hot dilute H_2SO_4 resolves it into water and the phenyl imide Its salts are soluble in water — AgA white pp, crystallising from water in shining scales

Phenyl-imide $\text{C}_2\text{H}_5(\text{OH}) \begin{array}{l} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{array} \text{NPh}$ [170°] Formed by heating malic acid with aniline and crystallising from water Groups of delicate needles, ν sol water, alcohol, and ether

Inactive malic acid $\text{CO}_2\text{HCH}_2\text{CH}(\text{OH})\text{CO}_2\text{H}$ [c 108°] (Pictet, *B* 14, 2648), [c 114°] (Kekulé), [135°] (Pasteur, Loydl, Bischoff) Occurs as calcium salt in the leaves of the common ash (*Fragaria vesicaria*) (Gintl, *J* 1868, 800, Garot, *J* 1853, 409)

Formation — 1 By mixing equal parts of laevo- and dextro malic acids (Van't Hoff, jun, *B* 18, 2170, *R T C* 4, 130) — 2 By reducing racemic acid with HIAq (Bremer, *Bl* [2] 25, 6) — 3 By the action of nitrous acid on inactive aspartic acid obtained from fumarimide (Pasteur, *A Ch* [3] 34, 46, *A* 82, 330) — 4 By the action of moist Ag_2C on bromo succinic acid (Kekulé, *A* 117, 126, 130, 24) — 5 By heating fumaric acid with a large quantity of water at 150°–200° (Jungfleisch, *Bl* [2] 30, 147) — 6 By heating fumaric acid (1 pt) with NaOH (4 pts) and water (40 pts) for 100 hours at 100° (Linne mann & Loydl, *A* 192, 80, *B* 9, 925) — 7 To gether with fumaric acid, by treating di β chloro propionic ether with a weak alcoholic solution of KCy , and boiling the product with potash (Wergo & Tanatar, *A* 174, 367) Also in like manner from di β bromo propionic acid (Tanatar, *B* 13, 160) — 8 From chloro ethanetri carboxylic ether $\text{CO}_2\text{EtCH}_2\text{CCl}(\text{CO}_2\text{Et})_2$, and dilute alcoholic KOH (Bischoff, *A* 214, 49)

Properties — Crystallises more readily than active malic acid, being less soluble in water and not deliquescent, or at any rate less deliquescent than the active acid ν e sol water, ν sol alcohol, ν sl sol ether When heated at 200° it yields fumaric acid

Salts — NH_4HA trimetric crystals (Van't Hoff) — NH_4HA aq monoclinic crystals *abc* = 5856 1 5377, β = 68° 12' — CaA granular pp, sl sol water — CaA aq — CaA 2 aq nodules of transparent crystals (Pasteur) The acid calcium salt resembles that of the active acid except that its crystals exhibit hemihedral faces The lead salt melts under water, but crystallises less easily than the inactive salt The lead salt obtained by Tanatar from di bromo propionic acid did not melt under water — AgA

By crystallising the cinchonine salt Bremer (*B* 13, 352) was able to separate it into salts of laevo and dextro malic acid

Ethyl derivative $\text{C}_2\text{H}_5(\text{OEt})(\text{CO}_2\text{H})_2$ [86°] Obtained by saponifying its di ethyl ether (Purdie, *C J* 39, 348) Transparent crystals (from ether), sol water Not ppd by lead subacetate, but in neutral and feebly acid solution it is ppd by lead nitrate and, more slowly, by neutral lead acetate Fuming HI at 120° reduces it to succinic acid — CaA insoluble — AgA sl sol water — BaA aq hygroscopic, ν sol water

Di ethyl ether of the ethyl derivative $\text{C}_2\text{H}_5(\text{OEt})(\text{CO}_2\text{Et})_2$ (135°–200°) at 250 mm From fumaric ether and NaOEt , the product being neutralised (Purdie)

Isobutyl derivative $\text{C}_2\text{H}_5(\text{OC}_4\text{H}_9)(\text{CO}_2\text{H})_2$ Crystalline, deliquescent mass (Purdie) — CaA insol water — AgA flocculent, insol water

The following compounds are probably also derivatives of the same inactive malic acid —

Amic acid $\text{CO}_2\text{HCH}_2\text{CH}(\text{OH})\text{CONH}_2$ **Malamic acid** [146°] Obtained, together with its ether, by boiling the amide of diazo succinic ether with water (Curtius, *J pr* [2] 83, 479) Colourless prisms, ν sol water, alcohol, and ether

Methyl ether of the amic acid $\text{CO}_2\text{MeCH}_2\text{CH}(\text{OH})\text{CONH}_2$ [105°] Formed,

together with methyl fumaramate, by boiling methyl diazo succinamate

$\text{CO}_2\text{Me CH}_2\text{CH}(\text{CONH}_2)$ with slightly acidified water (Curtius, *J pr* [2] 88, 482) Silky plates, v e sol alcohol, ether, and water With benzoic acid at 150° it forms crystalline $\text{CO}_2\text{Me CH}_2\text{CH}(\text{OBz})\text{CONH}_2$ [80°], v sol ether

Benzoyl derivatives of the ethyl ether of the amic acid

$\text{CO}_2\text{Et CH}_2\text{CH}(\text{OBz})\text{CONH}_2$ [97°] Formed by heating ethyl diazo succinamate with HOBz , at 145° Colourless rhombohedra

Dextro-malic acid $\text{CO}_2\text{H CH}_2\text{CH}(\text{OH})\text{CO}_2\text{H}$ [c 100°] Formed from dextro asparagine (from sprouting vetch seeds) by treatment with nitrous acid (Pittet, *B* 19, 1693) The cinchonine salt is obtained by crystallisation from the cinchonine salt of inactive malic acid Resembles ordinary malic acid, except that it is dextrorotatory

Isomeride of malic acid $\text{C}_4\text{H}_6\text{O}_5$ [155° - 168°] Formed by heating acetylene dibromide (5 pts) with KCy (4 pts) and alcohol (28 pts) at 100° , and saponifying the resulting nitrile with potash (Sabanejeff, *A* 216, 275) Crystals, v sol water— $\text{Ag}_2\text{A}''$

Isomalic acid of Kammerer (*J pr* 88, 321, *A* 139, 257) is identical with citric acid (Ostwald, *B* 21, 3534)

Paramalic acid is described as **DIGLYCOLLIC ACID**

Iso-malic acid $\text{CH}_2\text{C}(\text{OH})(\text{CO}_2\text{H})_2$ [c 140°] From bromo iso succinic acid and moist Ag_2O (Schmoger, *J pr* [2] 14, 77, 19, 168, 24, 38) Crystals, v sol water, alcohol, and ether At 170° it splits up into CO_2 and lactic acid In active Its neutral solutions give no pp with CaCl_2 (unlike methyl tartaric acid, which gives a pp on warming)— BaA'' 2aq amorphous pp S l at 100° Loses its water of crystallisation at 130° (unlike methyl tartaric acid)— PbA'' Does not melt under water— $\text{Ag}_2\text{A}''$ needles

Methyl-tartaric acid $\text{CH}_3\text{C}(\text{OH})(\text{CO}_2\text{H})_2$ [178°] Obtained from pyruvic acid by addition of KCy and HCl , the product being boiled with baryta water (Bottlinger, *B* 14, 148, 17, 144) Rhombohedral crystals Decomposes on fusion, giving off CO Boiling conc HClAq splits it up into CO and lactic acid— BaA'' aq (dried at 130°) Heavy crystalline powder, ppd on boiling— ZnA'' 2aq crystalline powder— $\text{Ag}_2\text{A}''$ aq white crystalline powder

Reference—**BROMO MALIC ACID**

MALLOTOXIN $\text{C}_{11}\text{H}_{10}\text{O}_5$ or $\text{C}_{11}\text{H}_8\text{O}_5$ May be extracted by CS_2 from finely-divided kamala, a yellow dye got from the seeds of *Mallotus Philippensis* (A G Perkin & W H Perkin, jun, *B* 19, 8109) Flesh coloured needles, insol water, v sol hot alcohol Dissolves readily in alkalis, forming a yellowish red solution Ac_2O yields a di acetyl derivative, r ROTTLEIN

MALOBURIC ACID $\text{C}_3\text{H}_4\text{N}_2\text{O}_4$ v e

$\text{CO} \begin{smallmatrix} \text{NH CO} \\ \text{NH CO} \end{smallmatrix} \text{CH CO NH}_2$ (?) Formed, as ammonium salt, by heating barbituric acid (malonyl urea) with urea at 160° (Baeyer, *A* 135, 312) Formed also by boiling cyanuromalic acid with HClAq (Nencki, *B* 5, 888) Ppd by adding HCl to solutions of its salts as a granular pp, which, when quite pure, can be obtained in crystals Dissolves completely in bromine and

water, forming di bromo barbituric acid Nitric acid converts it into nitro barbituric (dilituric) acid— KA'' long needles S l in hot water

MALONAMIC ACID v **MALONIC ACID**

MALONAMIDE v *Amide of MALONIC ACID*

MALONANILIC ACID v *Mono-amide of*

MALONIC ACID

MALONIC ACID $\text{C}_3\text{H}_4\text{O}_4$ v e $\text{CH}_2(\text{CO}_2\text{H})_2$ Mol w 104 [184°] (Krafft & Noerdlinger, *B* 22, 816) S 109 at 1° , 138 at 16° (Miczynski, *M* 7, 258), 109 at 15° (Bourgoin, *Bl* [2] 33, 423) H F 212,700 (Stohmann, Kleber & Langbein, *J pr* [2] 40, 206) H C v 207,900 H C p 207,300 (S, K & L), 208,650 (Lougumme, *C R* 107, 597) Heat of solution = -4573 Heat of neutralisation by NaOH 27,120 (Gal & Werner, *Bl* [2] 46, 803), 26,650 (Massol), by KOH 27,800, by NH_3 25,040, by BaO.H , 30,135, by CaO.H , 27,090 (Massol, *C R* 107, 257, 393, 108, 813, 1060, 109, 27) S H (0° to 50°) 2832, (0° to 110°) 3262 (Hess, *P* [2] 35, 410)

Occurrence—In beet root (Lippmann, *B* 14, 1183)

Formation—1 Discovered by Dessaignes (*C R* 47, 76) as a product of the slow oxidation of malic acid by cold aqueous $\text{K}_2\text{Cr}_2\text{O}_7$.—2 By the action of alkalis or acids on cyano acetic acid (semi nitrile of malonic acid) or cyano acetic ether (Kolbe, *A* 131, 349, Hugo Muller, *C J* 17, 109)—3 By oxidation of allylene or propylene with cold alkaline KMnO_4 (Berthelot, *J* 1867, 335)—4 By boiling barbituric acid with potash (Baeyer, *A* 130, 143, Heintzel, *A* 139, 129)—5 By boiling mucobromic acid with baryta water (Jackson & Hill)—6 From di chloro acrylic ether by treatment with Ag_2O at 125° , and saponifying the product (Wallach & Hunaeus, *A* 193, 25)—7 By treating $\text{CBr}_3\text{CO}_2\text{CH}_2\text{CBr}_3$ with fuming HNO_3 (Demole, *B* 11, 1714)

Preparation—1 From ethylic, or better from potassic, chloro acetate Chloro acetic acid (100 g) dissolved in water (200 g) is neutralised by K_2CO_3 (75 g), mixed with KCy (70 g), and warmed The reaction heats the liquid to boiling and is soon over KOH (100 g) is now added, and the liquid boiled as long as NH_3 escapes The liquid is then acidified with HCl , evaporated to dryness, and the malonic acid extracted by ether (H v Miller, *J pr* [2] 19, 326, cf Finkelstein, *A* 133, 338)—2 Chloro acetic acid (100 pts) is dissolved in twice its weight of water, and neutralised with potassium carbonate (75 pts) To the solution is added 75 to 80 pts potassium cyanide (98 p.c), and the mixture heated for two hours, with continual renewal of the evaporated water The remaining mass is decomposed with concentrated potash When the odour of ammonia has disappeared the solution is neutralised with hydrochloric acid, and ppd as a calcium salt This is decomposed with the requisite quantity of oxalic acid, the residue extracted with ether, and the solution evaporated (Conrad, *A* 204, 121)—3 By dissolving chloro acetic acid (100 gms) in double its weight of water, saturating the solution with potassium bicarbonate (110 gms), adding potassium cyanide (75 gms), and warming on the water bath At the end of the reaction double the volume of concentrated hydrochloric acid is added and the precipitation of potassium chloride rendered complete by passing in a current of HCl gas The

potassium and ammonium chlorides are filtered off, and the filtrate evaporated. The nearly dry residue is taken up with ether, which on evaporation yields pure malonic acid (70 gms) (Bourgoin, *A Ch* [5] 20, 271).—4 Chloro acetic ether is boiled with pure KCy dissolved in 70 p.c. alcohol for 4 hours. The alcohol is distilled off, and the residue mixed with dilute HCl and evaporated to dryness. The cyano acetic ether is extracted with ether and decomposed by fuming HClAq at 100° (Petrieff, *J R* 10, 64, *B* 7, 400).—5 In like manner from bromo acetic ether (Franchimont, *B* 7, 216).

Properties—Triclinic laminae or prisms. Decomposes a little over its melting point into CO₂ and acetic acid, but when heated under 10 mm pressure it may be sublimed. V sol water, alcohol, and ether. When heated with Ac₂O, malonic acid gives a reddish yellow liquid with greenish yellow fluorescence.—001 g is sufficient for this test (Kleemann, *B* 19, 2030). A small quantity of malonic acid treated with urea and POCl₃ yields a product which when evaporated with nitric acid leaves a residue which gives with ammonia the purple colour due to murexide (Grimaux, *C R* 88, 85).

Reactions—1 A solution of the free acid is hardly affected by the passage of an electric current. But the electrolysis of a concentrated alkaline solution gives off oxygen, CO, and CO₂ at the positive pole, without any hydrocarbon (von Miller, Bourgoin, *A Ch* [5] 20, 80, *C R* 90, 608).—2 Malonic acid (5g) heated with bromine (10 c.c.) and water (12 c.c.) for 18 hours at 120° to 145° gives bromoform, tri bromo acetic acid, CO₂, and HBr (Bourgoin, *Bl* [2] 34, 215).—3 HNO₃ (SG 1.53) in the cold gives off CO₂ (2 mols) (Franchimont, *R T C* 3, 422).—4 PCl₅ gives malonyl chloride and a compound C₂H₂ClO₂, crystallising in needles [122°], decomposed by water and alcohol with evolution of CO₂ (Béhal, *A Augur, Bl* [2] 50, 631).—5 Malonic acid (1 pt), NaOAc (1 pt), and Ac₂O (3 pts) at 100° forms a brownish yellow acid C₁₁H₂O₈. The sodium salt C₁₁H₂NaO₈ is v sol water, alkaline, and conc H₂SO₄ in sol HOAc. Its solutions exhibit fluorescence, but on heating CO₂ is evolved and the fluorescence disappears. An acetic acid solution of the salt C₁₁H₂NaO₈ boiled with a solution of phenyl hydrazine acetate forms CO₂, NaOAc, and C₁₀H₂O₈(N NHPh)₂, a substance insol water and ether, v sol alcohol and HOAc, forming a green solution in conc H₂SO₄, and melting with decomposition about 180° (Kleemann, *B* 19, 2030).—6 Benzoic aldehyde and HOAc forms benzylidene malonic acid C₆H₅CH(CO₂H)₂.—7 Propionic aldehyde and HOAc gives CH₃CH₂CH(CO₂H)₂ (Komnenos, *A* 218, 168).—8 *o*-Oxy benzoic aldehyde and HOAc at 100° forms coumarin-carboxylic acid (Vol 11 p 269).—9 Cinnamic aldehyde and HOAc at 100° gives phenyl-butene dicarboxylic acid C₆H₅CH=CHCH(CO₂H)₂ (Stuart, *C J* 49, 366).—10 Heated with phenyl thiocarbimide it gives acetanilide and the dianilide of malonic acid (Moine, *Ann Chem Farm* [4] 4, 201).

Salts—The salts, with the exception of those of the alkali metals, are sparingly soluble in water, more soluble in dilute malonic acid, HOAc, or nitric acid (Finkelstein, *A* 133, 338).—NaHA' aq: well defined crystals (F.).—

NaHA' aq trimetric prisms (Shadwell, *J* 1891, 699).—Na A' aq (Mulder, *Bl* [2] 29, 532, cf Massol, *C R* 107, 393).—KHA' aq prisms.—KHA' monoclinic prisms (Haushofer, *J* 1881, 699).—KA' 2aq deliquescent monoclinic crystals. Gives CO₂ and hydrogen on electrolysis (H von Miller).—K₂A' aq monoclinic prisms (H)—NH₄HA' very deliquescent crystals. Heat of formation from solid malonic acid and NH₄ 22,780 (Massol, *C R* 108, 1060).—(NH₄)₂A' very deliquescent needles. Heat of formation from solid malonic acid and NH₄ 41,015.—BaA' 2aq bulky flocculent pp gradually becoming crystalline. Crystallises from water in long slender needles. At 100° it loses aq, and when heated in a current of hydrogen at 140° it becomes anhydrous. BaA' aq is not dehydrated by heating in air at 150° (Pinna, Bischoff, *A* 179, 84). S 14 at 0°, 20 at 18°, 32 at 70° (Miczynsky, *M* 7, 261). Heat of solution —3830 (Massol, *C R* 109, 29).—CaA' 2aq monoclinic needles (from water). Ppd in gelatinous form on adding CaCl₂ to a solution of ammonium malonate. S 3 at 0°, 37 at 20°, 47 at 72° (Miczynsky). According to Massol (*C R* 108, 813) this salt separates in small brilliant scales on slow evaporation of its solution at 35°.—CaA' 4aq silky needles. Obtained by slow evaporation at 15° (Massol). V sol water. May be dehydrated in a current of hydrogen at 135°.—SrA' small brilliant scales (Ossipoff, *C R* 108, 815).—MgA' 2aq, MgA' aq, and MgA' 3aq are described by Finkelstein as crystalline powders.—ZnA' 2aq monoclinic crystals.—MnA' 2aq trimetric prisms.—CoA' 2aq monoclinic crystals (Haushofer).—NiA' 2aq bluish green powder.—CdA' deliquescent.—CdA' 4aq monoclinic crystals.—CdA' 12aq triclinic (Haushofer, *J* 1882, 362).—PbA' crystalline powder, sol HOAc.—CuA' 3aq blue triclinic crystals (H).—CuO A' bluish green pp.—AgA' crystalline pp, not blackened by boiling water.—Ethylamine salt NEt₃HA' gives at 180° water and the

whence concentrated caustic potash solution forms NHEt CO CH CH CO₂H [126°] (Piutti, *C C* 1888, 1529).

Methyl ether Me₂A' (181.5° cor) SG 1.1603, $\frac{d}{4}$ 1.1511 (Perkin, *C J* 45, 509), $\frac{d}{4}$ 1.1753 (W.) M M 5.28 at 17° SV 137.6 (Wiens, *A* 253, 297). From silver malonate and MeI (Osterland, *B* 7, 1286). Oil, sol alcohol and ether.

Mono-ethylether CO₂Et CH₂ CO₂H. When alcoholic KOH (1 mol) is added to alcoholic malonic ether the liquid forms a crystalline pulp of CO₂Et CH₂ CO₂K composed of needles (Van't Hoff, *B* 7, 1571, Freund, *B* 17, 780). PCl₅ converts it into CO₂Et CH₂ COCl (170°–180°).

Ethyl ether CH₃(CO₂Et)₂ (198° cor) (Perkin, *C J* 45, 508), $\frac{d}{4}$ 1.0761 (Wiens) SG 1.0610, $\frac{d}{4}$ 1.0525 M M 7.41 at 14° SH 439 at 0°, 45 between 10.6° and 82.2° (R Schiff, *Zent Phys Chem* 1, 376, *G* 16, 454) SV 185.1 (Wiens, *A* 253, 297).

Preparation.—1 Calcium malonate is boiled with H₂SO₄ and 4 times the theoretical quantity of alcohol for 24 hours (Conrad, *B* 12, 749).—

2 Chloro acetic acid (250 g) is dissolved in water (500 g) and K_2CO_3 (187 g), KOy (175 g) is added, and the whole heated on a sand bath until the reaction begins. The product is evaporated until its temperature is 135° , and is then allowed to cool. When cold it is treated with two-thirds of its weight of alcohol and gaseous HCl is passed in. The product is poured into iced water, extracted with ether, dried over $CaCl_2$, and distilled (Venable a Claisen, *A* 288, 131). Tricarballic ether (287°) is obtained as a by product (Daumichen, *C C* 1888, 1347).

Reactions—1 Water at 150° gives CO_2 and acetic ether (Hjelt, *B* 13, 1949).—2 Boiling with *m* amido benzoic acid and a little alcohol forms $CH_3(CO NH C_6H_4 CO_2 H)_2$, a powder which will not melt and is insol water, hardly sol boiling alcohol, sol dilute NH_4Ag , and dissolves without change in conc H_2SO_4 (Schiff, *A* 232, 143, *B* 17, 403, *G* 15, 534). The intermediate compound $CO_2 Et CH_2 CO NH C_6H_4 CO_2 H$ [173°] is also formed at the same time.—3 Chlorine forms chloro malonic ether.—4 Cautious treatment with nitric acid (5 pts of SG 1.5) gives nitro malonic ether (Franchimont a Klobbie, *R T C* 8, 283).—5 According to Lang (*B* 19, 2937) zinc methyl or zinc ethyl act in the cold, forming phloroglucin tricarboxylic ether, methane, and ethane.—6 When a mixture of malonic ether (1 mol) and EtI (2 mols) is heated with zinc there is formed ethane and ethyl-malonic ether (90 p.c. of the theoretical amount) (Damlar, *A* 20, 203). When malonic ether (20 g), EtI (100 g), and granulated zinc are heated with inverted condenser at 100° there is formed di ethyl malonic ether (Joulowsky, *J pr* [2] 39, 446).—7 With allyl iodide and zinc there is formed di-allyl malonic ether and propylene (Matvéeff, *J pr* 39, 452).—8 When malonic ether (2 mols) is treated with glyoxal (1 mol) and zinc chloride it forms di oxy butane tetracarboxylic ether $(CO_2 Et)_2 CH CH(OH) CH(OH) CH(CO_2 Et)_2$ (Polonowsky, *A* 246, 1).—9 With benzoic aldehyde and HCl it forms benzylidene malonic ether $C_6H_5 CH C(CO_2 Et)_2$ (Claisen a Cremer, *A* 218, 129).—10 Furfuraldehyde and acetic anhydride give furfuryl methenyl malonic ether $C_4H_3O CH C(CO_2 Et)_2$, which boils with slight decomposition at 293° , and gives on saponification the acid ether $C_4H_3O CH C(CO_2 H)(CO_2 Et)$ [102.5°], and finally the acid $C_4H_3O CH C(CO_2 H)_2$ [187°], which may be reduced by sodium amalgam to $C_4H_3O CH_2 CH(CO_2 H)_2$ [125°] (Marckwald, *B* 21, 1081).—11 Aldehyde forms $CH_2 C(CO_2 Et)_2$, and $CH_2 CH_2 C(CO_2 Et)_2$ (Komnenos, *A* 218, 145).—12 Diazobenzene chloride forms benzene azo malonic acid, identical with the phenyl hydrazide of mesoxalic acid (R Meyer, *B* 21, 118).

Sodium malonic ether $CHNa(CO_2 Et)_2$ is formed, with evolution of hydrogen, by dissolving sodium in malonic ether. The reaction is stopped by the crust of the sodium compound which forms on the surface of the metal, but this may be removed by adding alcohol (2 vols) which first forms $NaOEt$, and this then reacts with the malonic ether. The sodium malonic ether crystallises on cooling, and may be freed from alcohol by heating to 150° in a current of hydrogen (Conrad, *B* 12, 750). If, however, it be required merely for synthetical purposes the presence of alcohol is for the most part not injurious, and

the mixture of malonic ether and alcoholic $NaOEt$ may be used at once. This reacts upon organic halogen compounds thus—

$CHNa(CO_2 Et)_2 + XI = CHX(CO_2 Et)_2 + NaI$, the reaction being energetic at first but often requiring heat to finish it. If the substances are mixed in the right proportion the end of the reaction is recognised by the solution becoming neutral. Water is then added, and if X is a hydrocarbon radicle, $CHX(CO_2 Et)_2$, separates as an oil, which may be purified by fractional distillation. The resulting $CHX(CO_2 Et)_2$ still contains hydrogen displaceable by sodium, and if it be mixed with alcoholic $NaOEt$ and another halogen compound say YI , the reaction

$CNaX(CO_2 Et)_2 + YI = NaI + CXY(CO_2 Et)_2$, takes place (Conrad a Bischoff, *A* 204, 121). When the substituted malonic ethers are saponified acids are obtained, which at 150° or 160° give off CO_2 , and leave derivatives of acetic acid $CHX(CO_2 H)_2 = CO_2 + CH X CO_2 H$, $CXY(CO_2 H)_2 = CO_2 + CHXY CO_2 H$.

Hence malonic ether may be used, like acetoacetic ether, to effect the synthesis of organic acids of the general formula $CXYH CO_2 H$ where X and Y may be alkyls, groups like $CH_2 CO_2 Et$, or other radicles. When it is desired to prepare a di alkyl malonic ether it is not necessary to perform the operation in two stages, for the proper quantity of $NaOEt$ (2 mols) may be added all at once, and then the alkyl iodide (2 mols). By the action of $AcCl$ on sodio malonic ether in ethereal solution it may be converted into acetyl-malonic ether (120° at 17 mm), which is soluble in KOH aq., the yield is 55 p.c. of its weight. This ether forms an oxim and a phenyl hydrazide and therefore appears to be $CH_3 CO CH(CO_2 Et)_2$. When sodio aceto-acetic ether is acted upon by chloroformic ether $ClCO_2 Et$ the same ketonic ether $CH_3 CO CH(CO_2 Et)_2$ should be formed, but the product is found to be insol conc KOH aq., and to boil at a higher temperature (127° at 17 mm). It is decomposed by cold dilute KOH , and gives CO_2 and alcohol. The latter compound would therefore appear to be $CH_3 C(OCO_2 Et) CH CO_2 Et$ (Michael, *Am* 10, 158, *J pr* [2] 37, 473, cf Lange, *B* 20, 1325).

Reactions—1 EtI gives ethyl malonic ether. 2 Benzyl chloride gives mono and di benzyl malonic ether and regenerated malonic ether (Bischoff a Siebert, *A* 239, 94).—3 Malonic ether (32 g), sodium (9.2 g), dry alcohol (200 g) and chloroform (12 g) react thus (Conrad a Guthzeit, *A* 222, 250) $2CNa(CO_2 Et)_2 + CHCl_3 = 3NaCl + CNa(CO_2 Et)_2 + CH(CO_2 Et)_2$, forming sodium di carboxy glutaric ether (q.v.).—4 Trimethylene bromide reacts with formation of $(CO_2 Et)_2 C < \begin{smallmatrix} CH_2 \\ CH \end{smallmatrix} > CH_2$ (Perkin, jun, *C J* 51, 1, 702, 820).—5 $NaOEt$, allyl iodide, and iso butyl iodide gives an acid $C_8H_{14}O_4$, instead of allyl isobutyl-malonic acid.—6 Chloro-formic ether $ClCO_2 Et$ forms methane tricarboxylic ether $CH(CO_2 Et)_3$ (Conrad a Bischoff, *A* 214, 31, Claisen, *B* 21, 3567).—7 Tri bromo-di-nitro-benzene dissolved in ether reacts with formation of $C_6H_2Br(NO_2)_2 CH(CO_2 Et)_2$ [75°], although bromobenzene does not react (Jackson a Robinson, *B* 21, 2034).—8 Phthalyl chloride (1 mol) added to sodium-malonic ether (2 mols) dissolved in ether forms phthalyl malonic ether $C_8H_8O_4$,

[76°], phthalyl-dimalonic ether $C_{12}H_{10}O_8$ [48 5°], and 'phthaloxyl dimalonic' ether $C_{12}H_{10}O_8$, 116 5° (Wishnoen, *A* 242, 23) — 9 Treatment with the *chloride of mono-ethyl phthalate* $CO_2Et \cdot C_6H_4 \cdot COCl$ dissolved in benzene forms $(CO_2Et \cdot C_6H_4 \cdot CO)_2 \cdot C(CO_2Et)_2$ [above 180°] (Zelinsky, *B* 20, 1012) — 10 In alcoholic solution it is probably converted by carbonic acid gas into $(CO_2Et)_2CH \cdot CO_2Na$ (Michael, *J pr* [2] 35, 458) — 11 *Carbon disulphide* added to an alcoholic solution of sodium malonic ether gives yellow plates of $(CO_2Et)_2CNa \cdot CS_2Na$ — 12 SO_2 acts according to the equation $SO_2 + CHNa(CO_2Et)_2 + HOEt = CH_2(CO_2Et)_2 + NaO \cdot SO \cdot OEt$ — 13 *Resorcin* dissolved in alcoholic sodium malonic ether gives a greenish blue fluorescence, when after a few days the liquid is poured into water and acidified a small pp of needles of a condensation product $C_{11}H_{10}O_8$ [191°] is got. A little above its melting point it is split up into CO_2 and (β) methyl um belliferone of which it is probably the carboxylic acid (Michael, *J pr* [2] 37, 469) — 14 *Sulphur* dissolves in alcoholic sodium-malonic ether, and at 100° crystals separate. From these, acids liberate a stinking oil (thio tartaric ether?) — 15 With alcohol and *cinnamic ether* at 100° it forms $C_{11}H_{10}O_8$ (305°–310°). It is probably $Ph \cdot CH(CHNa \cdot CO_2Et) \cdot CH(CO_2Et) \cdot CO_2Et$, for on saponifying and heating the resulting acid, phenyl glutaric acid $CO_2H \cdot CH_2 \cdot CHPh \cdot CH_2 \cdot CO_2H$ is got (Michael, *J pr* [2] 35, 349) — 16 *Phenyl cyanate* $PhNCO$ acts violently upon an alcoholic solution of sodium malonic ether with formation of $(CO_2Et)_2CH \cdot CONHPh$ [124°] and the salt of an acid $C_{12}H_{10}NO_8$ [172°] (Michael, *J pr* [2] 35, 452) — 17 *Phenyl thio carbimide* forms crystalline $C_{11}H_{10}Na_2SNO_8$, whence acids separate $\cdot NHPh \cdot CS \cdot CH(CO_2Et)_2$ [60°] (Michael, *Am* 9, 124) — 18 *Urea* dissolves in malonic ether and rhombic prisms of $OHNa \cdot \begin{smallmatrix} CO-NH \\ CO-NH \end{smallmatrix} \cdot CO$ separate, whence acids liberate barbituric acid (Michael, *J pr* [2] 35, 456) — 19 *Thio urea* gives similarly flat plates of sodium thio barbiturate $CHNa \cdot \begin{smallmatrix} CO-NH \\ CO-NH \end{smallmatrix} \cdot CS$, whence acids liberate thio barbituric acid, which crystallises in six sided plates from water — 20 *Acetamide* forms crystalline $C_{10}O_4N_2Na_2H_8$, the reaction which occurs being $2CHNa(CO_2Et)_2 + 2CH_3 \cdot CO \cdot NH_2 = C_2O_4Na_2N_2H_8 + CH_3 \cdot C(CO_2Et)_2 + 2HOEt$ — 21 $CSCl_2$ forms $CS \cdot C(CO_2Et)_2$, which crystallises in flesh coloured needles [178°] (Bergreen, *B* 21, 337) — 22 *Iodine* forms $(CO_2Et)_2CH \cdot CH(CO_2Et)_2$ 23 *Di bromo maleic ether* yields 'di malonyl maleic' ether [75°], whence by saponification the corresponding acid $C_{10}H_8O_{12}$ [148°] may be obtained. This acid, the formula of which is $(CO_2H)_2CH \cdot C(CO_2H) \cdot C(CO_2H) \cdot CH(CO_2H)_2$, may be better called butylene hexa-carboxylic acid. It crystallises in plates, v sol water, and forms the salts, Na_2A^{10} 10aq and Ag_2A^{11} , and the ethers Me_2A^{12} [129°] and Et_2A^{13} [75°] (Pum, *M* 9, 450) When the acid is heated it splits up into CO_2 and butylene tetracarboxylic acid $CO_2H \cdot CH_2 \cdot C(CO_2H) \cdot C(CO_2H) \cdot CH_2 \cdot CO_2H$ [176°] 24 *Dry cyanogen chloride* forms cyano malonic ether (Haller, *Ch* [6] 16, 419)

Di-sodium-malonic ether

$CNa_2(CO_2Et)_2$. Obtained by ppg malonic ether (1 mol.) with $NaOEt$ (2 mols.) (Bischoff & Rach,

B 17, 2782) Very unstable Iodine converts it into $(CO_2Et)_2O \cdot C(CO_2Et)_2$

Ethyl propyl ether EtPrA" (211°) $SG \frac{1}{2}$ 10498 SV 207 8 (Wiens, *A* 253, 297)

Propylether PrA" (228°) $SG \frac{1}{2}$ 10271 SV 234 6 (Wiens, *A* 253, 297) SH (from 11 6° to 82 3°) 453 (R Schiff, *G* 17, 286)

Butyl ether (C₄H₉)₂A" (251 5°) $SG \frac{1}{2}$ 10049 SV 269 1 (Wiens, *A* 253, 297)

Chloride $CH_2(COCl)_2$ (58° at 27 mm) From malonic acid and $CSCl_2$ heated above 100° (Béhal & Auger, *Bl* [2] 50, 594) Liquid Smells slightly like chloral

Amide $CH_2(CONH_2)_2$ [170°] (Van't Hoff, *Ar Néerl* 10, 274) SG 83 at 8° (Henry, *Bl* [2] 43, 618) From malonic ether (50 cc) by shaking with strong aqueous NH_3 (150 cc) (Osterland, *B* 7, 1286, Freund, *B* 17, 133) The yield, in 2 days, is 75 p c Silky needles (from dilute alcohol), insol alcohol and ether Boiling aqueous NH_3 converts it into ammonium ma-

lonamate Salt $\begin{smallmatrix} CO \cdot NH \\ CO \cdot NH \end{smallmatrix} \cdot Hg$ white amorphous powder, insol alcohol and ether, sl sol hot water, v sol $HClAq$ (Freund)

Di-methyl amide $CH_3(CO \cdot NHMe)_2$ [128°] (F), [125°] (Henry), [136°] (Fianchimont, *R T C* 4, 199) Formed by the action of methylamine on malonic ether (Freund, *B* 17, 133) Small flat needles v e sol water and alcohol, sl sol ether Fuming HNO_3 converts it into $CH_2(CO \cdot N(NO_2)Me)_2$ [150°]

Di-ethyl amide $CH_2(CO \cdot NHEt)_2$ [149°] Six sided tables (Wallach & Kamenski, *B* 14, 170)

Ethylene diamide $CH_2 \cdot \begin{smallmatrix} CO \cdot NH \\ CO \cdot NH \end{smallmatrix} \cdot C_2H_4$

Formed by heating malonic ether or malonamide with ethylene diamine (Freund, *B* 17, 137) Crystalline solid v sol water, nearly insol alcohol

Amide-anilide $CONH_2 \cdot CH_2 \cdot CONHPh$ [163°] Obtained by heating malonamide with 1 mol of aniline for $\frac{1}{2}$ hour at 200°–220° (Freund, *B* 17, 135) Fine white felted needles Sol hot water and alcohol

Mono anilide $CO_2H \cdot CH_2 \cdot CO \cdot NHPh$ *Phenyl-malonamic acid* *Malonamic acid* *Malonphenylamic acid* [132°] Formed by boiling the amide anilide with milk of lime (Freund, *B* 17, 135) Formed also by heating sodiumacetyl phenyl carbamate $C_6H_5Nac \cdot CO_2Na$ for 5 or 6 hours at 130°–140° under pressure (Seifert, *B* 18, 1359), and by heating malonic acid (1 mol) with aniline (1 mol) at 105° (Rugheimer, *B* 17, 737) Large colourless monoclinic crystals, or slender needles At its melting point it breaks up quantitatively into CO_2 and acetanilide — $A^{14}Ag$ small white needles — $A^{15}Ca$ 4½aq large needles

Ethyl ether of the mono-anilide $CO_2Et \cdot CH_2 \cdot CONHPh$ [89°] From aniline and $CO_2Et \cdot CH_2 \cdot COCl$, both dissolved in benzene (Rugheimer & Hoffmann, *B* 17, 739) Crystals (from ether-ligroin) l sol water and ligroin, v e sol alcohol and benzene

Anilide $CH_2(CONHPh)_2$ [225°] Obtained by boiling malonic ether or malonamide with aniline (Freund, *B* 17, 134) White needles Insol water and ether, e sol hot alcohol

Tri-bromo anilide

$\text{CH}_2(\text{CO NH C}_6\text{H}_2\text{Br}_3)_2$ [148°] White silky needles, sl sol alcohol, insol water (Freund, *B* 17, 780)

Methyl-anilide $\text{CH}_2(\text{CO NMePh})_2$ [109°]

Obtained by boiling malonic ether with an excess of methyl aniline (Freund, *B* 17, 187) Colourless trimetric prisms *V* sol alcohol

Mono o-toluide

[2] $\text{CH}_2\text{C}_6\text{H}_4\text{NH CO CH}_2\text{CO}_2\text{H}$ *o*-Tolyl malonic acid Colourless needles, *v* sol water and alcohol Melts about 140°, giving off CO_2 — CaA'_2 3aq small needles, *m* sol water— BaA'_2 aq needles, *v* sol water— CuA'_2 2aq prisms (Rugheimer & Hoffmann, *B* 18, 2971)

Ethyl ether of the o-toluide EtA' [74°]

Long needles, sl sol ether and ligroin

Mono m-toluide

[8] $\text{CH}_2\text{C}_6\text{H}_4\text{NH CO CH}_2\text{CO}_2\text{H}$ [101°]

Mono-p-toluide

[4] $\text{CH}_2\text{C}_6\text{H}_4\text{NH CO CH}_2\text{CO}_2\text{H}$ Obtained by heating malonic acid with *p*-toluidine (Rugheimer & Hoffmann, *B* 17, 740, 18, 2971) Long colourless needles, sol water, alcohol, ether, and chloroform At 150° it gives off CO_2 PCl_5 converts it into tri chloro methyl quinoline [134°]— CaA'_2 4½aq long needles, *m* sol water— BaA'_2 5aq needles— AgA'_2 cheesy white pp or needles, sl sol water— CuA'_2 2aq minute needles, sl sol hot water— ZnA'_2 glistening plates, *m* sol water

Ethyl ether of the p-Toluide EtA' plates, *v* sol alcohol

Mono phenyl hydrazide

$\text{PhN}_2\text{H CO CH}_2\text{CO}_2\text{H}$ [154°] Formed from malonic acid and aqueous phenyl hydrazine acetate at 100° (Fischer & Passmore, *B* 22, 2734) Needles, *v* sol water Its phenyl hydrazine salt $\text{PhN}_2\text{H}_2\text{CO CH}_2\text{CO}_2\text{N}_2\text{H}_2\text{Ph}$ is converted at 200° into $\text{CH}_2\text{C}(\text{CO})\text{N}_2\text{HPh}$, crystallising in white needles, [128°], *v* sol alcohol

Di phenyl dihydrazide

$\text{CH}_2(\text{CO N}_2\text{H Ph})_2$ [187°] From malonic acid or the amide of malonic acid and phenyl hydrazine at 200° (Freund & Goldsmith, *B* 21, 1241) Plates (from dilute alcohol) With COCl_2 it gives $\text{C}_6\text{H}_5\text{N}_2\text{O}_2$, which crystallises from HOAc in laminae [205°]

Semi nitrile $\text{CO}_2\text{H CH}_2\text{CN}$ *v* CYANO

ACETIC ACID

Nitrile $\text{CH}_2(\text{CN})_2$ *Methylene cyanide* [30°] (219°) (*H*), (223°) (Berthelot & Petit, *A Ch* [6] 17, 131) *HF*—43200 Obtained by heating cyano acetamide $\text{CN CH}_2\text{CONH}_2$ with P_2O_5 (Henry, *C R* 102, 1394, 1481) White solid Appears to be polymerised by prolonged action of heat Sol water, *v* sol alcohol and ether Burns with a purple edged flame Conc HClAq dissolves it with evolution of heat and formation of malonic acid HClAq at 150° in sealed tubes forms CO_2 and chloro acetic acid With ammoniacal AgNO_3 it gives a white pp $\text{CAG}_2(\text{CN})_2$ (?), which explodes when heated

References—AMIDO-, BROMO-, CHLORO-, CYANO-, NITRO-, METHYL-, ETHYL-, PROPYL-, METHYL ETHYL-, and BENZYL MALONIC ACID

MALONYL-UREA *v* BARBITURIC ACID

Isomalonylurea $\text{CO} \begin{smallmatrix} \text{NH CH} \\ \text{NH CO} \end{smallmatrix} \text{CO OH}$ is formed, together with amido uracil, by reducing

nitro-uracil (Behrend, *A* 229, 89, *B* 21, 999)

It is converted by bromine into an acid isomeric with dialuric acid The acetyl derivative $\text{C}_6\text{H}_5\text{N}_2\text{O}_2\text{Ac}$ crystallises from hot water in prisms

MALONOXYL-AMIDO-BENZENE *v* CARB OXY PHENYL MALONAMIC ACID

MALTOBIONIC ACID $\text{C}_{12}\text{H}_{22}\text{O}_{12}$ Formed by oxidising maltose (1 pt) by bromine (1 pt) in water (7 pts) (E Fischer & Meyer, *B* 22, 1941) Almost colourless syrup *V* sol water, sl sol alcohol, insol ether It reduces Fehling's solution By heating with dilute sulphuric acid it is split up into dextrose and gluconic acid

Salt— CaA'_2 hard shining mass, *v* sol water

MALTONIC ACID Identical with GLUCONIC ACID (*q v*)

MALTOSE *v* SUGAR

MALYL UREIDE, so called, *v* URAMIDO

SUCCINIC ACID

MANDELAMIDINE $\text{C}_8\text{H}_{10}\text{N}_2\text{O}$ *se*

$\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C}(\text{NH}_2)\text{NH}$ [110°] From the hydrochloride of mandelic imido ether and alcoholic NH_3 (Beyer, *J pr* [2] 31, 387) Needles, *v* sol water and alcohol, sl sol ether Very unstable— B'HCl [214°] Prisms (from cold water)

MANDELAMIDOXIM $\text{C}_8\text{H}_9\text{N}_2\text{O}_2$ *se*

$\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C}(\text{NH}_2)\text{NOH}$ [159°] From the nitrile of mandelic acid and hydroxylamine (base) (Tiemann, *B* 17, 126) Crystals (from alcohol) Insol benzene, sl sol cold, *v* sol hot, water *V e* sol aqueous acids and alkalis FeCl_3 colours its aqueous solution blood red. It does not reduce Fehling's solution

Reactions—1 The hydrochloride, mixed with conc aqueous potassium cyanate forms $\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C}(\text{NOH})\text{NH CO NH}_2$ [127°]—2 Phenyl cyanate forms the corresponding $\text{Ph CH}(\text{OH})\text{C}(\text{NOH})\text{NH CO NHPh}$ [155°]—3 Excess of AcCl , or a mixture of Ac_2O and NaOAc forms $\text{C}_6\text{H}_5\text{CH}(\text{OAc})\text{C} \begin{smallmatrix} \text{N O} \\ \text{N} \end{smallmatrix} \text{C CH}_3$

[52°]—4 COCl_2 , added to its benzene solution, forms $(\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C}(\text{NH}_2)\text{N O})_2\text{CO}$ [131°]—5 Chloroformic ether, ClCCl_3Et , gives the compound $\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C}(\text{NH}_2)\text{N O CO Et}$ [107°] Salts— NaA' needles— HA'HCl (Gross, *B* 18, 1074)

Ethyl ether EtA' [89°] Slender needles, sl sol cold water With phenyl cyanate it forms $\text{Ph CH}(\text{OH})\text{C}(\text{NOEt})\text{NH CO NHPh}$ [119°]

Benzyl ether $\text{C}_6\text{H}_5\text{CH}_2\text{A}'$ [103°] From mandelamidoxim, NaOEt , and benzyl chloride (Gross, *B* 18, 1030) Needles

Acetyl derivative

$\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C}(\text{NH}_2)\text{NOAc}$ [140°] From mandelamidoxim and Ac_2O Crystals (from alcohol) Insol cold water, sol alcohol, ether, and benzene With water at 100° it forms

$\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C} \begin{smallmatrix} \text{N O} \\ \text{N} \end{smallmatrix} \text{C CH}_3$ [65°]

Di-acetyl derivative

$\text{C}_6\text{H}_5\text{CH}(\text{OAc})\text{C}(\text{NH}_2)\text{NOAc}$ [113°] From mandelamidoxim and a slight excess of AcCl (from alcohol)

Benzoyl derivative

$\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{C}(\text{NH}_2)\text{NOBz}$ [149°] From mandelamidoxim and BaCl (1 mol.) With

AcCl it gives $C_6H_5CH(OAc)C(NH_2)NOBz$ [165°] (Gross)

MANDELIC ACID $C_6H_5O_2$, *rac*
 $C_6H_5CH(OH)CO_2H$ *Phenyl-glycolic acid*
Oxy-phenyl acetic acid Mol w 152 [115°]
(Müller, *Ar Ph* [3] 2, 385), [118°] (Glaisen, *B* 10, 847, Lewkovitch, *B* 16, 1568) S G ± 1.361 (Schröder, *B* 12, 1612) S 16 at 20° *Heat of solution* -3100 *Heat of neutralisation* by NaOH +13860 (Berthelot, *A Ch* [6] 7, 185)

Formation -1 Discovered by Winckler (*A* 18, 310), who obtained it by heating bitter almond water with HCl, the benzoic aldehyde reacting with the HCy present (Liebig, *A* 18, 319) -2 By heating amygdalin with fuming HClAq (Wöhler, *A* 66, 238) -3 By boiling the compound of benzoic aldehyde with $KHSO_4$ for several hours with KCy and alcohol The nitrile $C_6H_5CH(OH)CN$ thus formed is saponified by dilute HClAq (O Müller, *B* 4, 980) -4 By reducing phenylglyoxylic acid $C_6H_5COCO_2H$ with sodium-amalgam (Schwebel, *B* 10, 2045) -5 From di-bromo acetophenone $C_6H_5COCHBr_2$ by boiling with dilute KOHAq (120), the compound $C_6H_5COCH(OH)_2$ being a theoretical intermediate product (Engler a Wöhler, *B* 20, 2202) -6 In small quantity, by boiling pseudo-phenyl hydantoin with baryta (Pinner, *B* 21, 2327) -7 By boiling a chloro-phenyl-acetic acid with alkalis (Spiegel, *B* 14, 239)

Preparation - Benzoic aldehyde (100 g), water (3500 c c), fuming HClAq (200 g), and 4 times the calculated quantity of hydrogen cyanide are boiled for 36 hours The product is evaporated at 100°, the residue extracted with ether, the extract evaporated, and the mandelic acid left recrystallised from water (Wallach, *A* 193, 38, cf Strecker, *A* 75, 27)

Properties - Large trimetric crystals, v sol water, alcohol, and ether Inactive to light By crystallisation of the cinchonine salt it can be separated into equal quantities of the dextro- and levorotatory acids If *Penicillium glaucum* is grown in it the levorotatory acid is destroyed, leaving the dextrorotatory (Lewkowsch, *B* 16, 1568)

Reactions -1 $KMnO_4$ and KOH convert it, in the cold, into phenyl glyoxylic acid (R Meyer a A Baur, *A* 220, 39) -2 Dry distillation yields benzoic aldehyde -3 Boiling with MnO_2 and H_2SO_4 yields benzoic aldehyde and CO_2 -4 Fuming $HBrAq$ converts it slowly in the cold, quickly at 125°, into a bromo-phenyl-acetic acid, whence alcoholic NaOEt forms the ethyl derivative of mandelic acid (Glaser a Radziszewsky, *Z* [2] 4, 140) -5 Fuming HClAq at 140° gives α -chloro-phenyl-acetic acid -6 Phosphorus and HI reduce it to phenyl acetic acid -7 When taken internally it passes unaltered into the urine (Schotten, *H* 8, 68) -8 Cannot be nitrated Conc NHO_3 forms benzoic aldehyde (Liebig, *A* 18, 321), dilute HNO_3 forms phenyl glyoxylic acid (Zincke a Hannaus, *B* 10, 1488) -9 Dilute H_2SO_4 in sealed tubes at 130° converts mandelic acid nearly quantitatively into benzoic aldehyde and formic acid (Biedermann, *B* 19, 638) 10 Chloral at 120° forms

which forms large transparent crystals [83°], insol water, sol alcohol and chloroform (Wal-

lach, *A* 193, 1) -11 *Phenyl-hydrazine* forms a compound [182°], crystallising in needles and almost insol boiling water (Reissert a Kayser, *B* 22, 2928)

Salts - The ammonium and potassium salts are very soluble and difficult to crystallise The Ba salt forms small needles S 8 at 24°, 16 at 100° (Zinn, *Z* 1868, 710) The lead salt is a crystalline powder, scarcely sol water - CuA' , (dried at 100°) - AgA' crystalline pp May be crystallised from water

Methylether MeA' [48°] Small laminae (from benzene-ligroin) (Zincke a Breuer, *B* 13, 636)

Ethyl ether $PhCH(OH)CO_2Et$ (254°) Formed by the action of water on the hydrochloride of mandelic imido ether (*qv*) Solidifies in a freezing mixture, but is liquid at ordinary temperatures (Beyer, *J pr* [2] 31, 389) But Naquet and Lugunin (*A* 139, 300), who prepared it from silver mandelate and EtI, say it melts at 75°

Methyl derivative $PhCH(OMe)CO_2H$ [72°] Formed from $PhCHClCO_2Me$, $MeOH$, and $NaOMe$ (R Meyer a H Boner, *A* 220, 44, *B* 14, 2392) Needles grouped concentrically (on solidifying) or thick tables (from light petroleum) V sol alcohol or ether, sl sol cold water or cold petroleum KOH and $KMnO_4$ forms phenyl glyoxylic acid

Salts - $NaA'2aq$ - $BaA'2aq$ - CaA' - $CuA'2aq$ - AgA'

Methylether of the methyl derivative $PhCH(OMe)CO_2Me$ (246° cor)

Ethyl derivative $C_6H_5CH(OEt)CO_2H$ From $C_6H_5CHBrCO_2H$ and alcoholic KOEt Viscid mass - AgA' pulverulent pp

Phenyl derivative $PhCH(OPh)CO_2H$ [108°] From methyl α -chloro phenyl acetate and sodium phenate (R Meyer a H Boner, *A* 220, 51) Radiating groups of slender needles (from water) V sl sol cold water, v e sol alcohol or ether KOH and $KMnO_4$ convert it into phenyl glyoxylic acid HNO_3 forms picric acid and benzoic aldehyde - $NaA'3aq$ - CuA' - AgA'

Acetyl derivative of the ethyl ether $C_6H_5CH(OAc)CO_2Et$ [74°] From mandelic acid by successive treatment with AcCl and alcohol (Naquet a Lugunin, *A* 139, 302) Slender needles (from ether) Insol water, v sol alcohol and ether

Amide $C_6H_5CH(OH)CONH_2$ [132°] S 3 at 24° S (boiling 93° c alcohol) 100 (Z) Formed, together with benzoic aldehyde, by heating the compound $(C_6H_5CHO)CNH$ with water or alcohol at 180° (Zinn, *Z* [2] 4, 709) Formed also by allowing a mixture of the nitrile with fuming HClAq to stand in the cold (Tiemann a Friedlander, *B* 14, 1967) Likewise obtained by the action of NH_3 on mandelic ether, and by heating mandelic imido-ether (C Beyer, *J pr* [2] 31, 386) Prismatic needles or plates Sol hot, sl sol cold, water, sl sol ether, v sol alcohol Decomposed by acids and alkalis with production of mandelic acid A polymeride (?) melts at 190°

Nitrile $C_6H_5CH(OH)CN$ [-10°] S G. 1.124 Obtained by adding fuming HClAq to a mixture of benzoic aldehyde and KCy (Spiegel, *B* 14, 239, Völkel, *A* 52, 861) Oil, sol alco-

hol and ether Dissolved in ether, mixed with alcohol (1 equivalent), and treated with HCl gas it forms $C_6H_5CH(OH)C(OEt)NH_2 \cdot HCl$ [125°] This is decomposed by water, forming NH_4Cl and mandelic ether (Beyer, *J pr* [2] 28, 190) At 170° mandelonitrile splits up into benzoic aldehyde and H_2C_4 Boiling aqueous HCl gives NH_4Cl and mandelic acid Fuming $HClAq$ forms the amide in the cold, but on heating it gives a chloro phenyl acetic acid NH_2 in the cold forms $C_6H_5CH(NH_2)CN$ Methylamine yields $C_6H_5CH(NHMe)CN$ Phenyl hydrazine produces the phenyl hydrazone of benzoic aldehyde (Reissert, *B* 17, 1451)

(*dextro*) Mandelic acid [133° cor] $[a]_D$ at 20° = +156 Prepared by converting inactive mandelic acid into the cinchonine salt and adding a crystal of cinchonine *dextro* mandelate to the aqueous solution when the *dextro* salt crystallises out, leaving the *laevo* salt in solution It can also be obtained by growing *Penicillium glaucum* in the inactive acid, which destroys the *laevorotatory* acid, leaving the *dextrorotatory* (Lewkowitsch, *B* 16, 1568) Resembles the *laevo*-acid, having the same solubility in water

(*laevo*) Mandelic acid [133°] *S* 864 at 20° $[a]_D$ at 20° = -158 Prepared by heating amygdalin with strong HCl for several hours on the water bath It can also be obtained from inactive mandelic acid which can be separated into equal quantities of the *laevo* and *dextrorotatory* acids by crystallisation of the cinchonine salt (Lewkowitsch, *B* 16, 1565, cf Wöhler, *A* 66, 240)

Nitro mandelic acid *v* Nitro oxy-phenyl-acetic acid

MANDELIC IMIDO ETHER

$PhCH(OH)C(NH)OEt$ [72°]

Preparation—Benzoic aldehyde (100 g) treated with KCN, dilute HCl and ether forms the cyanhydrin $PhCH(OH)CN$ which is dissolved by the ether If this is mixed with an equivalent of alcohol and dry HCl be passed in, the liquid being cooled, needles of the hydrochloride of mandelicimido ether (80g) are formed (C Beyer, *J pr* [2] 31, 3-4) $PhCH(OH)CN + EtOH + HCl = PhCH(OH)C(NH)OEt \cdot HCl$ These melt at [125°] The free ether is got by shaking these simultaneously with conc KOH and ether After evaporating the ether the residue is crystallised from ligroin

Properties—White needles Extremely soluble in ether, alcohol, and benzene

Reactions—1 At 140° the hydrochloride splits up thus $PhCH(OH)C(NH)OEt \cdot HCl = EtCl + PhCH(OH)CONH_2$, forming mandelic amide—2 Alcoholic NH_3 converts the hydrochloride into the hydrochloride of the amidine, $PhCH(OH)C(NH)NH_2 \cdot HCl$ This forms prisms [214°] Shaken with ether and potash, the free mandelic amidine, $PhCH(OH)C(NH)NH_2$, is dissolved by the ether It forms feathery needles of narcotic odour, melting at [110°]—3 Water quickly converts the hydrochloride into mandelic ether (*q v*) $C_6H_5CH(OH)C(NH)OEt \cdot HCl + H_2O = C_6H_5CH(OH)COOEt + NH_3 \cdot HCl$

MANDRAGORINE $C_8H_9NO_3$ [α 79°]

Extracted from powdered mandragora root by alcohol The extract is evaporated and the residue treated with very dilute acid The alkaloid is liberated from the acid solution by

adding K_2CO_3 and shaking with ether (Ahrens, *A* 251, 312) Hygroscopic brittle mass Picric acid gives with a solution of mandragorine hydrochloride light yellow needles of the picrate. Iodine in $KIAq$ gives an oily periodide K_2FeCy_4 gives no pp Phosphotungstate gives a white pp The sulphate is crystalline and very deliquescent Dropped into the eye, its solution causes enlargement of the pupil— $B'HANCl_4$ [155°], yellow plates, sol hot water and $HClAq$ — $B'_2H_2P_2Cl_4$ [194°] Red nodules or yellow plates (from hot water)— $B'HCl_4HgCl_2$ [160°] Plates or needles (from water) or long slender needles (from alcohol) *V* sol alcohol (Ahrens, *B* 22, 2161)

Mandragora root also contains a second alkaloid of which the platinochloride [181°] and aurochloride [147°-153°] are crystalline (Ahrens)

MANGANATES Salts of the form M'_2MnO_4 derived from the hypothetical acid H_2MnO_4 , *v*. MANGANESE, OXYACIDS *op*, p 185

MANGANESE Mn At *w* 55 Mol *w* probably same as At *w* (*v infra*) [α 1800°-1900°] *S* G 6.85 to 8.01, according to Glatzel, *S* G of pure Mn is 7.3921 at 22° (*B* 22, 2857) *S* H 14° to 97° 1217 (Regnault, *A Ch* [3] 67, 427, specimen contained Si) Chief lines in emission spectrum are 6521, 6016, 6013, 4823, 4783, 4765, 4762, 4753, 4235, 4027 (Thalén) For absorption spectrum of Mn vapour *v* Lockyer *A Roberts* (*Pr* 23, 344)

Occurrence—The metal does not occur uncombined Mn compounds are widely distributed, the chief are *pyrolusite* MnO_2 , *braunite* Mn_2O_3 , *manganite* $Mn_2O_3 \cdot H_2O$, *hausmannite* Mn_3O_4 , *psilomelane* $(Mn, Ba, K)O_4 \cdot MnO_2$, *manganesc spar* $MnCO_3$, *manganese blende* MnS Small quantities of Mn compounds are found in sea water (Forchhammer, *Pr E* 2, 303), in many mineral waters (Buchanan, *Pr* 24, 593), in blood (Cotteneau, *J* 1849 530, Burn de Buisson, *J* 1852 377, Campani, *B* 5, 287), in the liver (Béchamp, *C R* 49, 895), in milk (Polacci, *Naturforscher*, 4, 122), in human urine (Horsford, *J* 1851 602), in wines, cereals, most vegetables used as human food, and in considerable quantities in tea (Vaumené, *C R* 98, 1056, 1416) Mn also occurs in the sun's atmosphere (Comu, *C R* 86, 315, 530)

Manganese dioxide was recognised as a compound of a distinctive metal by Scheele in 1774, it had previously been looked on as a compound of iron The metal Mn was first isolated by Gahn Native MnO was long known as *magnesia nigra* (probably because of its supposed magnetic properties), a new medicine was introduced in the early years of the eighteenth century, and was called *magnesia alba*, seemingly in contradistinction to *magnesia nigra*, when *magnesia nigra* was shown to contain a distinctive metal, this metal was called sometimes *magnesium* and sometimes *manganesium*, finally the name *magnesium* was retained for the metal of *magnesia alba*, and the name *manganesium* (hence *manganese*) was given to the metal of *magnesia nigra*

Formation—1 By reducing the oxides by C at a white heat.—2 By reducing MnF_3 or $MnCl_3$ by Na or by Mg—3 By heating Mn amalgam in a stream of H, the amalgam is made by the reaction of Na amalgam with $MnCl_2Aq$ (Giles,

P M [4] 24, 328, Roussin, *Bl* 6, 93) —4 By electrolysis MnCl_2 in a porous cell placed in a carbon crucible containing HClAq (Bunsen, *P.* 91, 619)

Preparation —1 Crystallised MnCl_2 is thoroughly dried by heating, it is then finely powdered and 100 grams are intimately mixed with 200 grams well dried and powdered KCl , the mixture is packed into a Hessian crucible which is loosely covered and heated in an air-furnace until the contents melt (the temperature must not be raised so high that white vapours begin to come off), the lid is removed and 15 grams Mg are thrown into the crucible in four or five portions, each weighing 3 to 4 grams, two to three minutes being allowed to elapse between the entrance of each piece, the lid is now replaced and the crucible is strongly heated for a few minutes, and then allowed to cool very slowly in the furnace. About 20 to 25 grams Mn are thus obtained as a compact regulus. If the temperature of the final heating is not sufficiently high, the regulus does not form a compact mass, if the temperature is too high and the heating is unduly prolonged, the KCl is vapourised and the surface of the Mn is oxidised (Glatzel, *B* 22, 2857) —2 Brunner (*P* 101, 264) recommends the following method —2 pts MnF_2 (obtained by dissolving moist MnCO_3 in HFAq , evaporating and drying at 100°) and 1 pt Na are arranged in alternate thin layers in a Hessian crucible, the mixture is pressed down and covered with NaCl over which is placed a layer of CaF_2 in small pieces (to prevent spitting), the crucible is covered and heated in an air furnace, at first gently, and then to near a white heat for about $\frac{1}{2}$ an hour, the crucible is then allowed to cool very slowly in the furnace —3 For an account of the older methods of preparing Mn from MnO_2 , *v* John (Gehlen's *Journ. Chem. Phys.* 3, 452), and Deville (*A Ch* [3] 46, 182). Tamm describes a method for obtaining approximately pure metal (99.91 p.c. Mn , 0.05 p.c. Fe , 1.15 p.c. Si , and 0.25 p.c. C) from MnO_2 (*C N* 26, 73, 111)

Properties —A white grey, lustrous, metal, very hard, brittle, may be highly polished, non magnetic (Glatzel). According to Glatzel (*B* 22, 2857), Mn prepared by reducing MnCl_2 by Mg (*v* Preparation No 1) is unchanged by keeping for months in a bottle closed with a glass stopper, but in moist air the surface undergoes slight oxidation. Mn is usually described as very easily oxidised in ordinary air, and as capable of decomposing water, with evolution of H , almost as rapidly as K . Mn obtained by Brunner (*v* Preparation No 2) by reducing MnF_2 by Na was scarcely oxidised in cold water. According to Bullock (*C N* 60, 20), Mn prepared by reducing the oxides by C is very easily oxidised, while specimens obtained by reducing MnCl_2 by Na are no more oxidisable than iron. It is probable that some specimens have contained small traces of Si and C which have affected the properties of the metal. Mn melts at a very high temperature ($c. 1800^\circ - 1900^\circ$), and is said to volatilise at a full white heat.

The atomic weight of Mn has been determined (1) by estimating Cl in MnCl_2 (Arfvedson, *S* 42, 202, Dumas, *A Ch* [3] 55, 151; Berzelius, *P* 18, 74), (2) by dissolving Mn in HNO_3 ,

and calcining the nitrate (Berzelius, *P* 8, 185), (3) by oxidising MnO to Mn_2O_3 by heating in air (*v* Hauer, *W A* 25, 133), (4) by reducing Mn_2O_3 in H , and weighing H_2O produced (Rawack, *P* 107, 605, 616), (5) by analysing Mn_2O_3 (Sohneider, *P* 107, 605), (6) by reducing AgMnO , and estimating Ag produced (Dewar, *A Scott*, *Pr* 35, 44), (7) by determining SH (Regnault, *A Ch* [3] 67, 427)

Molecular weight of manganese —Ramsay (*O J* 55, 521) has determined the lowering of the vapour pressure of Hg produced by dissolving Mn in Hg , the results render it probable that the molecular weight of Mn is the same as the atomic weight. This conclusion assumes the accuracy of Van't Hoff's law that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved substances, and it also supposes the molecular weight of liquid Hg to be the same as the atomic weight of Hg .

Mn is metallic in its physical, and some of its chemical, properties, but in many of its reactions it behaves as a non metal. The oxides MnO and Mn_2O_3 are basic, forming salts, such as MnSO_4 and $\text{Mn}(\text{SO}_4)_2$, of which the managanous salts, corresponding with MnO , are much the more stable. The oxide MnO reacts as a basic peroxide, *e.g.* with H_2SO_4 it forms MnSO_4 , and O , it also reacts with some positive oxides, *e.g.* CaO , to produce salts of the form $x\text{MO} \cdot y\text{MnO}$, when this oxide is treated with molten KOH in presence of O the salt K.MnO_4 is formed, in which Mn forms part of the acidic radicle. The oxides MnO , and Mn_2O_3 have also been isolated, both are very unstable, both react with water to form managanic acid HMnO_3 , the former (MnO_2) at the same time also producing MnO_2 , these oxides are distinctly acidic. The acid HMnO_4 has been isolated, and many salts derived from the hypothetical acid H.MnO_4 are known.

Mn shows marked analogies with the iron metals Fe , Ni , and Co , it is also related, although less distinctly, to the halogens, and it is also related to the chromium metals, Cr , Mo , W , and U . In the classification of the elements based on the periodic law, Mn occupies a position different from that of any known element: it is placed in the same group as the halogens (Group VII), and in the same family (even-series members) as F , but no member of this family coming after Mn (*i.e.* with a greater atomic weight than Mn) has yet been isolated, Mn finds a place in series 4 (K , Ca , Sc , Ti , V , Cr , Mn), all the members of which are metallic, and it is immediately followed by Fe , Ni , Co , and Cu . The strongly marked negative character of the halogens is impressed on Mn , but this is counterbalanced by the positive characteristics of the metals which come before and after Mn in order of atomic weights (*v* HALOGEN ELEMENTS, vol. II p. 666, also IRON GROUP OF ELEMENTS, this vol. p. 65).

The atom of Mn is divalent in the gaseous molecule MnCl_2 .

Reactions —1 Mn is oxidised in air or oxygen, forming MnO —2 Mn reacts energetically with dilute mineral acids forming salts of MnO 3 Fused with potassium nitrate or chlorate KMnO_4 is produced —4 Heated in bromine MnBr_2 is formed —5 When Mn is heated in a stream

of hydrogen chloride MnCl_2 is produced—6 Mn decomposes water readily, with evolution of H_2 . The reactions of the metal have not been much examined.

Combinations—Mn forms alloys with many metals, and compounds with most of the non metals, but few have been formed by the direct union of their elements.

Detection and estimation—Mn is usually detected by the colour its compounds impart to a borax-bead, and by the ppn of buff-coloured MnS by addition of NH_4 sulphide to an alkaline or neutral solution of Mn salts. Mn is usually estimated gravimetrically by ppn with NH_4Aq , heating the pp in air, and weighing as Mn_2O_3 . As MnO_2 is much used in technical chemistry it is necessary to have accurate and rapid methods for determining the quantity of this oxide in specimens of Mn ores, for descriptions of these methods, and also for other methods for estimating Mn, reference must be made to *Manuals of Analysis*.

Manganese, alloys of Several alloys of Mn have been prepared, none has been made by directly alloying Mn with other metals.

1 With *aluminum* Wöhler & Michel (*A* 115, 102) obtained a crystalline powder, having the composition MnAl_3 , by fusing together MnCl_2 , Al, and a mixture of NaCl and KCl.

2 With *copper* Alloys of Mn and Cu are obtained by reducing mixtures of MnO , and Cu with charcoal, an alloy containing 25 p.c. Mn is white, fairly hard, very elastic, and tolerably easily melted (Allen, *C* 22, 184). Alloys containing from 3 to 20 p.c. Mn resemble bronze (Valenciennes, *C* R 70, 607, v also Schrotter, *D P J* 210, 355, Prieger, *ibid* 177, 303, Gintl, *ibid* 224, 653).

3 With *iron* Alloys of Mn and Fe, containing from 8 to 80 p.c. Mn, are used in the manufacture of steel, under the names of *spiegeleisen* and *ferromanganese*. These alloys are prepared by heating MnO with iron filings and charcoal in the blast furnace, or in graphite crucibles, or by reducing a mixture of FeO and MnCO_3 on the hearth of a Siemens' furnace, and then fusing under a reducing flame.

4 With *mercury* An amalgam of Mn is obtained by reducing MnCl_2Aq by Na amalgam (Giles, *P M* [4] 24, 328), or also by electrolyzing MnCl_2Aq in contact with Hg (Ramsay, *C J* 55, 532, Moissan, *Bl* [2] 31, 149). Alloys of Mn with Pb, Sn, and Zn are described by Allen (*l c*) and Valenciennes (*l c*).

Manganese, arsenates of, v vol 1 p 309

Manganese, arsenide of Mn and As combine when heated together to redness. An arsenide, approximately As_3Mn_4 , occurs native (Kane, *P* 19, 145).

Manganese, arsenite of, v vol 1 p 306

Manganese, boride of By heating Mn_2O (v *Manganese, carbides of*) with B_2O_3 in a graphite crucible, Troost and Hautefeuille obtained small greyish violet crystals of MnB_2 (*C R* 81, 1263). This compound decomposes water at 100° and dissolves in acids with evolution of H_2 , it reacts with moist HgCl_2 to produce MnCl_2 , boric acid, and HCl.

Manganese, bromides of Only one bromide, MnBr_2 , has been isolated, the tetrabromide also perhaps exists in solution.

MANGANOUS BROMIDE, MnBr_2 , Manganese dibromide The hydrate $\text{MnBr}_2 \cdot 4\text{H}_2\text{O}$ is obtained as clear, red, deliquescent, crystals, by dissolving MnCO_3 in HBrAq , or by digesting Mn with Br (Balard, *J pr* 4, 178, Marignac, *Ann M* [5] 12, 7), crystallises in monoclinic forms, $a b c = 845 : 1 : 166$ (Marignac). The anhydrous salt MnBr_2 is obtained by heating powdered Mn in Br vapour, it forms a rose red deliquescent mass, heated in air it gives Br and Mn_2O_3 , Thomsen gives the thermal data— $[\text{Mn}, \text{Br}, \text{Aq}] = 106,120$ (*Th* 3, 271).

MANGANOUS BROMIDE, MnBr_2 , (Manganese tetrabromide) This compound perhaps exists in the green solution obtained by treating Mn_2O_3 or MnO , with HBr gas and dry ether, the solution is easily decomposed with formation of MnBr_2 (Nicklès, *C R* 60, 79).

Manganese, carbides of According to Brown (*J pr* 17, 492), the compound MnC is obtained by heating $\text{Mn}(\text{SCy})_2$ and MnC , by heating MnCy_2 , Troost and Hautefeuille obtained graphite-like, lustrous, crystals of MnC , by melting Mn in a charcoal crucible, and cooling slowly (*C R* 80, 960).

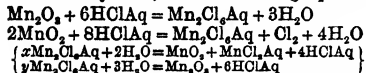

Manganese, chlorides of The only chloride of Mn which has been isolated is MnCl_2 . A solution of MnO_2 , or Mn_2O_3 , in conc. cold HClAq very probably contains Mn_2Cl_2 , perhaps also some MnCl_3 . The existence of MnCl_3 , described by Dumas, is very doubtful.

MANGANOUS CHLORIDE, MnCl_2 Mol w 125.74, Rose-coloured crystals of $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ are obtained by dissolving MnCO_3 , or any oxide of Mn, in HClAq , and evaporating, by heating the dried crystals in a stream of dry HCl, the anhydrous salt, MnCl_2 , is obtained. MnCl_2 is also formed by heating Mn, MnCO_3 , or Mn_2O_3 , in a stream of dry HCl. By heating very finely powdered MnO with half its weight of NH_4Cl gradually to redness, MnCl_2 is formed. MnCl_2 is very deliquescent, Brandes (*P* 22, 263) gives S at $10^\circ = 62.16$, at $31.25^\circ = 85.72$, at $62.5^\circ = 122.22$, at $87.5^\circ = 122.22$, and at $106.25^\circ = 123.81$. S in alcohol at $11^\circ = 50$. SG of $\text{MnCl}_2 = 2.478$ (Schröder), of $\text{MnCl}_2 \cdot 4\text{H}_2\text{O} = 1.913$ (Schröder), 2.015 (Boedeker). The tetrahydrated salt is isomorphous with $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$, monoclinic, $a b c = 1.1409 : 1.16406$ (Marignac, *Ann M* [5] 15). All water is removed at 100° . Thomsen gives the thermal data $[\text{Mn}, \text{Cl}_2] = 111,990$, $[\text{MnCl}_2, \text{Aq}] = 16,010$, $[\text{MnCl}_2, 4\text{H}_2\text{O}] = 14,470$ (*Th* 3, 270). Heated in O_2 , a crystalline oxide containing 37 p.c. MnO_2 is produced (Schulze, *J pr* [2] 21, 407). MnCl_2 melts, in absence of air, at a red heat and sublimes at higher temperature. Scott found VD at c $1200^\circ - 1500^\circ$ to be 132.3 (*Pr E* 14, 410).

MnCl_2 forms double salts with the alkali chlorides, of the composition $\text{MnCl}_2 \cdot 2\text{XCl} \cdot 3\text{H}_2\text{O}$. The best examined are those in which $\text{X} = \text{NH}_4$, Rb, and Cs, the NH_4 salt contains one H_2O only according to Rammelsberg (*J pr* 65, 181, confirmed by Pickering, *C J* 85, 672). The double salts are obtained by mixing MnCl_2Aq or a solution of an oxide of Mn in HClAq with the alkali chloride, and evaporating slowly (v Godeffroy, *B* 8, 9, v Hauer, *J pr* 63, 436). Another double salt $\text{MnCl}_2 \cdot 3\text{CuO} \cdot 8\text{H}_2\text{O}$ is formed by boiling MnCl_2Aq with powdered CuO , filtering, and cooling (André, *C R* 106, 854). The double

salt $\text{MnCl}_2 \cdot \text{HgCl}_2 \cdot 4\text{H}_2\text{O}$, is described by Bonsdorff (*P* 17, 131)

MANGANIC CHLORIDE, Mn_2Cl_7 , and MANGANESE TETRACHLORIDE, MnCl_4 . Neither of these chlorides has been isolated. Mn_2O_3 and MnO_2 dissolve in cold conc HClAq to form deep-brown liquids, which slowly evolve Cl_2 and after a time contain MnCl_2 . Nicklès (*d Ch* [4] 5, 161), by passing HCl into ether in which MnO_2 was suspended, obtained a green liquid, of varying composition and very unstable, one analysis gave results approximately agreeing with the formula $\text{MnCl}_2 \cdot 12\text{C}_2\text{H}_5\text{O} \cdot 2\text{H}_2\text{O}$. These results are quite inconclusive of the formation of MnCl_2 (cf Pickering, *C J* 35, 672). Fisher's experiments (*C J* 38, 409) led him to conclude that a solution of MnO_2 in cold conc HClAq contains MnCl_2 , but the more complete experiments of Pickering (*C J* 35, 654) make it very probable that Mn_2Cl_7 , and not MnCl_4 , is produced when either Mn_2O_3 or MnO_2 is dissolved in cold conc HClAq . When the solutions are decomposed by adding water, the pp varies in composition but may always be expressed as $x\text{MnO}_2 \cdot y\text{MnO}$, x varying from 16 to 36 and y being usually 5. Pickering expresses the reactions of HClAq with Mn_2O_3 and MnO_2 , and the decomposition of the solutions by H_2O , in the following equations —

The average values of x and y are 4 and 1 respectively. Christensen (*J pr* [2] 35, 57) thinks that Mn_2Cl_7 is the product of the reaction of cold HClAq with MnO_2 , he supposes that some MnCl_2 is produced at 10° . According to C, ether holding HCl in solution produces a solution of MnCl_2 when shaken with Mn_2O_3 . According to Vernon (*C S Proc* 1890 58), a solution of MnO_2 in conc HClAq evolves less than half the Cl_2 at ordinary temperatures, required by the equations given by Pickering (*supra*), at -18°C is evolved very slowly, and at -26° only 35 p.c of the available Cl comes off when air is drawn through the solution for two hours. Vernon thinks that MnCl_2 is the only higher chloride formed by dissolving MnO_2 , Mn_2O_3 , or Mn_3O_4 in cold conc HClAq .

Franke (*J pr* [2] 36, 38) obtained *chloromanganic acid*, H_2MnCl_4 , by adding KMnO_4 to ether containing HCl , shaking with dry ether, and surrounding the deep-blue liquid thus produced with a freezing mixture.

MANGANESE HEPTACHLORIDE, MnCl_7 (?) Dumas (*B J* 7, 112, 8, 177) described a greenish gas, condensing at -15° to -20° to a green brown liquid, produced by adding excess of conc H_2SO_4 to KMnO_4 , and throwing in small pieces of fused KCl or NaCl , he gave the formula MnCl_7 , to this substance. Aschoff's analyses of the compound proved the presence of O in it, and led to the formula MnO_2Cl (*J pr* 81, 29). The exact composition of the substance is not yet settled.

Manganese, chromate of, v vol 11 p 155

Manganese, cyanides of, v vol 11 p 342

Manganese, ferri- and ferro cyanides of, v vol 11 pp 335, 339

Manganese, fluorides of. Two fluorides of Mn have been certainly isolated, MnF_3 and

Mn_2F_7 . The existence in solution of MnF_3 is doubtful. Wohler obtained a gas by the reaction of H_2SO_4 with a mixture of K_2MnO_4 and KF . To this gas he assigned the composition MnF_3 , but the composition of the substance cannot be regarded as settled. Nicklès asserts the existence of Mn_2F_7 .

MANGANESE FLUORIDE, MnF_3 (Manganese difluoride). A reddish crystalline powder, obtained by dissolving Mn_2CO_3 in excess of HFAq and evaporating, undecomposed by heating to redness (Berzelius).

MnF_3 forms double compounds with SiF_4 , &c (Berzelius, Stolba, *C C* 1883 292, Mari-gnac, *J pr* 83, 202). These compounds, better regarded as silicofluoride, titanofluoride, &c, of Mn , have the composition $\text{MnXF}_3 \cdot 6\text{H}_2\text{O}$, where $\text{X} = \text{Si}, \text{Ti}$, or Sn , they are isomorphous, crystallising in hexagonal forms, $a : c = 1 : 515$ (Mari-gnac, *Ann M* [5] 15). There is also a zirconofluoride of Mn , $\text{MnZnF}_3 \cdot 5\text{H}_2\text{O}$, which crystallises in monoclinic forms, $a : b : c = 2 : 09 : 1 : 2515$ (*M l c*).

MANGANESE SESQUIFLUORIDE, Mn_2F_7 . Crystals of $\text{Mn}_2\text{F}_7 \cdot 6\text{H}_2\text{O}$ were obtained by Christensen (*J pr* [2] 35, 57) by dissolving artificially prepared MnO_2 in HFAq , filtering through spongy Pt , evaporating, and placing over H_2SO_4 . Boiling or diluting the solution of MnO_2 in HFAq produces an oxyfluoride.

The double salts $\text{Mn}_2\text{F}_7 \cdot 4\text{KF} \cdot 2\text{H}_2\text{O}$, $\text{Mn}_2\text{F}_7 \cdot 4\text{NH}_4\text{F}$, $\text{MnF}_3 \cdot 4\text{NaF}$, and $\text{Mn}_2\text{F}_7 \cdot 2\text{AgF} \cdot 8\text{H}_2\text{O}$ are described by Christensen (*l c* and *ibid* p 161). They are obtained by adding solution of the alkali fluoride to solution of Mn_2O_3 or MnO_2 in HFAq , washing with water containing HF , and drying on Pt , the Ag -salt is obtained by dissolving freshly pptd AgCl in HFAq , adding Mn_2F_7 in HFAq , and evaporating. According to Christensen, the salt $\text{Mn}_2\text{F}_7 \cdot 4\text{KF} \cdot 2\text{H}_2\text{O}$ is identical with the compound to which Nicklès gave the formula $\text{MnF}_3 \cdot 2\text{KF}$ (*C R* 65, 107).

MANGANESE TETRA and HEPTA FLUORIDES, MnF_4 and Mn_2F_7 (?) The former compound was supposed by Nicklès to exist in the solution of MnO_2 in HFAq (*C R* 65, 107), by adding KF or NaF the double salts $\text{MnF}_3 \cdot 2\text{K}(\text{Na})\text{F}$ were said to be formed. The investigations of Christensen (*J pr* [2] 35, 57, 161) have made it very probable that Mn_2F_7 , and not MnF_4 , is formed when MnO_2 or Mn_2O_3 is dissolved in HFAq (*v supra*, cf *Manganese chloride, supra*).

The formula MnF_3 was given by Wohler (*P* 9, 619) to a purple yellow gas obtained by adding conc H_2SO_4 to a mixture of 2 parts commercial K_2MnO_4 and 1 part CaF_2 in a Pt retort. The gas dissolves in water to form HMnO_4Aq and HFAq , and on evaporation HF and O are evolved, and MnF_3 remains. The composition of the gas is still very doubtful, no analyses are given in Wohler's paper.

MANGANO MANGANIC FLUORIDE, Mn_2F_7 . According to Nicklès (*C R* 67, 448), brown crystals, having the composition $\text{Mn}_2\text{F}_7 \cdot 10\text{H}_2\text{O}$, are obtained by reacting on MnO_2 with warm HFAq and evaporating.

Manganese, haloid compounds of. The compounds MnX_2 ($\text{X} = \text{F}, \text{Cl}, \text{Br}, \text{I}$) have been isolated. Mn_2F_7 has also been obtained in definite form. There are very strong reasons in favour of the existence of Mn_2Cl_7 in the solutions obtained by dissolving Mn_2O_3 or MnO_2 in cold conc HClAq .

The existence even in solution, of tetra haloid compounds, MnX_4 , is doubtful. Nicklès claims to have obtained mangano manganic fluoride Mn_2F_7 , corresponding with Mn_2O_7 . The only haloid compound of Mn which has been gasified is $MnCl_4$. The general formula MnX_3 probably expresses the atomic composition of the molecules of the more stable haloid compounds of Mn, the formula MnX_2 may or may not be molecular. The existence of hepta-haloid compounds MnX_7 , might be expected from the position of Mn in the periodic scheme of classification, but the existence of these compounds is extremely doubtful.

Manganese, hydroxides of, v Manganese, oxides and hydrated oxides of, for $HMnO_3$, v Manganese, oxyacids of

Manganese, iodide of MnI_2 . Obtained, with $4H_2O$, in rose red deliquescent crystals, isomorphous with $MnCl_2 \cdot 4H_2O$, by dissolving $MnCO_3$ in $HIAq$, and evaporating. Turns brown when exposed to air and light, heated in absence of air, it is not decomposed, heated in O it burns like tinder, evolving vapours of I . Thomsen gives the thermal data $[Mn, I, Aq] = 75,700$ (*Th* 3, 271).

Manganese, oxides and hydrated oxides of. The oxides MnO , Mn_2O_3 , Mn_3O_4 , MnO_2 , probably also MnO_3 and Mn_2O_5 , have been isolated. A number of oxides intermediate between Mn_2O_3 and MnO_2 , having the general form $xMnO_2 \cdot yMnO$, also exist. Hydrates of most of these oxides exist, but their stability is generally small. $Mn_2O_3 \cdot H_2O = H_2Mn_2O_4$ is known, it is an acid. The acid corresponding to MnO_2 (H_2MnO_4) has not been isolated, but salts of this acid (manganates) are known. The oxides MnO , Mn_2O_3 , and Mn_3O_4 are basic. MnO reacts with acids to form manganous salts MnX_2 ($X = NO_3, \frac{1}{2}SO_4, \&c$), Mn_2O_3 forms manganic salts Mn_2X_3 , which are readily reduced to MnX_2 , Mn_3O_4 does not form corresponding salts, but with acids yields MnX_2 and MnX_3 , or in some cases MnX_2 and MnO_2 . Nicklès, however, asserts the production of Mn_2F_7 by the action of $HFAq$ on Mn_2O_3 (*v Mangano manganic fluoride*, p 180). MnO_2 reacts with acid to form manganic salts Mn_2X_3 , or manganous salts MnX_2 , according to temperature. It is possible that a few salts corresponding with MnO_2 may exist, but their isolation is doubtful. MnO_2 also combines with some oxides more basic than itself to form *manganites*, salts of the form $xMO \cdot yMnO$. MnO_2 is very unstable, it does not form salts. The existence of $(MnO_2)_2SO_4$ is probable. With water MnO_2 forms $H_2Mn_2O_4 \cdot Aq$ and MnO_2 . Mn_2O_3 is very unstable, with water it forms permanganic acid, $H_2Mn_2O_4$.

The molecular weight of none of the oxides of Mn is known with certainty, as none has been gasified.

MANGANOUS OXIDE, MnO (*Manganese monoxide or protoxide*). SG 5 09, crystalline (Ram-melsberg), 5 18, *manganosite* (Blomstrand, B 8, 180).

Occurrence—In small quantities, as *manganosite*, in bright green hexagonal forms (Blomstrand, l c).

Preparation—1 By heating to redness in a Pt vessel a mixture of equal parts $MnCl_2$ and Na_2CO_3 , with a little NH_4Cl , $MnCO_3$ is formed

and then decomposed, the formation of higher oxides is prevented by the NH_4Cl , the residue is washed and dried (Liebig, A. Wohler, P 21, 578). 2 By heating any of the higher oxides of Mn, very finely divided, to redness in a stream of H until the powder is green. According to Wright a Menke (C J 37, 28), pure MnO can be thus obtained, even from specimens of MnO_2 , containing c 10 p.c of potash—3 $MnCO_3$ or $Mn_2C_2O_4$ is strongly heated in absence of air, and the product is then heated in H (Liebig, A 95, 116).—4 Deville (C R 53, 199) obtained MnO in bright green regular octahedra by heating MnO_2 in H containing a very little HCl .

Properties and Reactions—A grass green powder, Deville's crystalline specimen (*v supra*) formed lustrous, diamond like, green regular octahedra. According to Moissan (A Ch [5] 21, 199, 251), MnO prepared by reduction of higher oxides by CO at 140° is pyrophoric. When pure, MnO does not oxidise by exposure to air (Wright a Menke, C J 37, 28 note), but if it contains minute quantities of potash oxidation occurs. Heated in air or O , Mn_2O_3 is produced, if the heating is done carefully till the weight is constant at dull redness, Mn_2O_3 is produced (*v Gorgeu, C R 106, 743*). MnO melts at white heat in absence of air. It is not reduced by heating in H or CO , or with C at 500° 600° (Wright a Luff, C J 33, 523). When heated in H_2S , MnS and H_2O are formed. MnO reacts with acids to form manganous salts, MnX_2 ($X = NO_3, ClO_3, \frac{1}{2}SO_4, \&c$).

HYDRATE OF MANGANOUS OXIDE, $MnO \cdot H_2O$. Occurs in small quantities in Sweden, in white crystalline tablets, as *pyrochroite*. Prepared, as small white hexagonal prisms, by adding 300 grm KOH in 500 c c air free water to an air free solution of 15-17 grm crystallised $MnCl$ in 15 c c air free water, in a vessel filled with H or coal gas, heating to 160° , and allowing to cool (A de Schulten, C R 105, 1265). Rapidly oxidises in air. When a manganous salt is present the compound $2MnO \cdot MnO_2 \cdot xH_2O$ is formed, when exposed to O for several years the product is $MnO_2 \cdot MnO$ (Gorgeu, C R 108, 948). When NH_4Aq is added to solution of a manganous salt, $MnO \cdot H_2O$ is not pptd, as it is soluble in NH_4Aq , but this solution rapidly absorbs O from the air, and after a time all the Mn is pptd as hydrates of Mn_2O_3 . The presence of NH_3 salts hinders the oxidation process, solutions of double NH_4 Mn salts are scarcely changed in air if free NH_3 is absent. Thomsen gives the thermal data $[Mn, O, H^+O] = 94,770$, $[MnO^+H^+O] = 21,560$, $[MnO^+H^+H^+SO^+Aq] = 26,480$ (*Th* 3, 271).

MANGANO MANGANIC OXIDE, Mn_2O_3 (*Red oxide of manganese*).

Occurrence—As *hausmannite*, in small brownish black tetragonal forms, a c = 1 1 1537, SG 4 8.

Preparation—1 Pure $MnCl_2 \cdot Aq$ is pptd by $Na_2CO_3 \cdot Aq$, the pp is thoroughly washed, dried, and then heated to whiteness for some time until the weight is constant (*cf* Wright a Luff, C J 33, 520, with Reissig, A 108 27).—2 By strongly heating $Mn_2C_2O_4$ in air (Laassaigne, A Ch [3] 40, 329).—3 Crystals of *hausmannite* were obtained by Debray by strongly heating a mixture of $MnSO_4$ and K_2SO_4 in a Pt crucible (C R 52, 985), also by passing a very slow stream of HCl

over amorphous Mn_2O_3 heated to redness (Dewille, *C R* 53, 199), also by keeping molten MnCl_2 in an atmosphere laden with moisture (Gorgeu, *C R* 96, 1044), also by melting amorphous Mn_2O_3 with borax (Nordenskjöld, *P* 114, 112, *v.* also Debray, *Ann M* [5] 1, 124, Sidot, *C R* 69, 201, *v.* Hauer, *J pr* 63, 425, Ebell, *D P J* 220, 64, 155)

It is generally stated that Mn_2O_3 is produced by heating any of the other oxides of Mn to redness in air, according to the experiments of Dittmar (*C J* 1864 294) the composition of the product of heating MnO_2 in a mixture of O and N varies according to the pressure of the O, if the pressure of the O is about 19 atmos the product is approximately Mn_2O_3 , while if the pressure of the O is greater than about 26 atmos the product approximates more or less closely to Mn_2O_3 . The experiments of Wright and Luff (*C J* 33, 520), on the effect of heating MnCO_3 in air, showed that unless the heating is continued for a long time and the temperature is kept very high the product contains more O than Mn_2O_3 . According to Gorgeu (*C R* 106, 743), finely powdered Mn_2O_3 can be oxidised to $x\text{MnO}_2 \cdot y\text{MnO}$, finally to Mn_2O_3 , by heating in air

Properties and Reactions—A reddish brown solid powder, crystalline Mn_2O_3 is brown SG crystalline 4856, amorphous 4918 Mn_2O_3 is not changed when heated to a very high temperature. It is reduced to MnO by H, CO, and O (Bell, *C N* 23, 258, Muller, *P* 186, 160), reduction by CO begins at c 100°, by H at c 240°, and by C at c 420° (Wright & Luff, *C J* 33, 520) Mn_2O_3 with conc H_2SO_4 forms a solution containing MnSO_4 and $\text{Mn}_2(\text{SO}_4)_3$, when the acid is hot, only MnSO_4 is formed and O is evolved. With boiling HNO_3 , $\text{Mn}(\text{NO}_3)_2$ and MnO are produced. Hot conc HClAq produces MnCl_2 and evolves Cl. Fused with alkalis, alkaline manganate is formed. Cl in presence of an alkaline solution reduces an alkaline permanganate. The reactions of Mn_2O_3 with acids, KIAq , &c., suggest the constitution $2\text{MnO} \cdot \text{MnO}_2$ (Pickering, *C J* 35, 657)

HYDRATES OF MANGANO-MANGANIO OXIDE, $\text{Mn}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ Such hydrates appear to exist, but their composition varies. Gorgeu (*C R* 84, 177) says a yellowish green hydrate is formed by shaking an aqueous solution of a manganese salt with alkali in presence of air. Hydrates of Mn_2O_3 are also said to be formed by placing finely-powdered MnO_2 in excess of an ammoniacal solution of MnCl_2 and heating (*cf J* Otto, *A* 93, 372) Veley (*C J* 41, 63) obtained a substance nearly agreeing in composition with the formula $8\text{Mn}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, by heating $x\text{MnO}_2 \cdot y\text{MnO} \cdot z\text{H}_2\text{O}$ in H to 200°

MANGANIO OXIDE, Mn_2O_3 (*Sesquioxide of manganese*)

Occurrence—As *braunite* in quadrate octahedra, SG 4752 (Rammelsberg, *P* 124, 513) The hydrate $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ occurs native as *manganite*

Preparation—1 The pp—approximately $\text{MnO}_2 \cdot x\text{H}_2\text{O}$ —obtained by passing Cl into $\text{Na}_2\text{CO}_3\text{Aq}$ holding finely powdered MnCO_3 in suspension, is made into a thin cream with conc H_2SO_4 and slowly heated on an oil bath to 100°, at which temperature O is suddenly evolved, and the mass becomes thicker and

greyish violet in colour, it is then heated to 138° until it is dark green. The impure $\text{Mn}_2(\text{SO}_4)_3$ thus produced is placed on a warm porous plate, by which H_2SO_4 is absorbed, it is then rubbed with conc HNO_3Aq , free from HNO_2 , again dried on a porous tile, and then warmed to 130°. The $\text{Mn}_2(\text{SO}_4)_3$ thus produced is exposed to air, when it rapidly deliquesces to form a violet solution, which afterwards becomes turbid from separation of $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ ($\text{Mn}_2(\text{SO}_4)_3 + 4\text{H}_2\text{O} = \text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O} + 3\text{H}_2\text{SO}_4$) The brown solid which separates is washed, dried at 100° and then gently heated until the water is removed (Carius, *A* 98, 53)—2 According to Schreider (*P* 107, 605), Mn_2O_3 is obtained by heating MnO_2 , MnO , or Mn_2O_3 in O (but *v.* account of Dittmar's experiments under *Manganio manganio oxide*, *supra*) Moissan says that artificially prepared Mn_2O_3 goes to MnO when heated in O to 230° (*A Ch* [5] 21, 232). According to Berthelot (*A Ch* [5] 15, 185) and Knab, Mn_2O_3 is obtained by heating MnCl_2 , MnBr_2 , or MnI_2 in air or O. This oxide is also said to be formed, with evolution of O, by passing H_2O vapour over heated KMnO_4 , Gorgeu (*C R* 108, 1106) obtained MnO , by allowing ppd MnCO_3 to remain in contact with aerated water for 10 years, also by exposing $\text{MnO} \cdot \text{H}_2\text{O}$ to O in presence of excess of a manganous salt, also by exposing solutions of MnSO_4 , MnCl_2 , and $\text{Mn}(\text{C}_2\text{H}_3\text{O}_2)_2$ to sunlight

Properties and Reactions—A black powder, SG 4325, the mineral *braunite* forms brownish black, very hard, lustrous quadrate octahedra, SG 4752 Deoxidised at white heat to Mn_2O_3 . Soluble in conc H_2SO_4 , forming a reddish liquid, which evolves O on warming, and then contains MnSO_4 , boiled with dilute $\text{H}_2\text{SO}_4\text{Aq}$ or HNO_3Aq , MnO is separated, and manganous sulphate or nitrate goes into solution (Christensen, *J pr* [2] 23, 81) Soluble in cold conc HClAq , forming a brown liquid, which most probably contains Mn_2Cl_6 (*v. Manganio chloride*, p 180)

Mn_2O_3 is a basic oxide, the corresponding salts are not numerous, they are readily reduced to manganous salts. $\text{Mn}(\text{SO}_4)_2$ combines with alkali sulphates to form alums. Mn_2O_3 reacts with hot HClAq , with KIAq , and other reagents, as if it were $\text{MnO} \cdot \text{MnO}_2$ (Pickering, *C J* 35, 657) Laugier (*C R* 104, 1508) describes several compounds of Mn_2O_3 with SeO_2 , prepared by the reaction of MnO_2 with $\text{H}_2\text{SeO}_4\text{Aq}$

HYDRATE OF MANGANIO OXIDE, $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ Occurs native as *manganite*, SG 4335, iso-morphous with *gibbsite* and *diaspore*, the corresponding Fe and Al compounds. The preparation of $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is described under *Manganio oxide* (*v. supra*), it forms a brownish black powder. Warmed with conc H_2SO_4 to c 100°, $\text{Mn}_2(\text{SO}_4)_3$ is formed without evolution of O (Carius, *A* 98, 53) According to Carius (*lc*), $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is not dissolved by dilute $\text{H}_2\text{SO}_4\text{Aq}$ even on gently warming, but if a little MnO is present solution occurs in the cold. $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is said by Hermann (*P* 74, 303) to dissolve in tartaric acid, forming a brownish red liquid, from which manganous tartrate separates on standing, the liquid becoming colourless and now containing formic acid and CO_2 . In a stream of H_2S , a little MnSO_4 , and also MnS

and Mn_2O_3 are formed (Wagner, *D P J* 195, 532) When moist $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is shaken with *magnesia alba*, K_2CO_3 , or Na_2CO_3 , or even with water, and much air, nitrates are produced according to Reichardt (*Henneberg's J für Landwirthsch* 26, 167)

MANGANESE PEROXIDE, MnO_2 (*Manganese dioxide*)

Occurrence—As *pyrolusite*, in iron black, opaque, rather brittle trimetric crystals, $a:b:c = 776:11066$, SG 4.82 to 4.97. The name is supposed to have been given from the use of the mineral to remove the colour from glass, coloured by compounds of iron (*pur* = fire, and *laver* = wash out)

Preparation—Pure MnCO_3 is dissolved in as small a quantity as possible of dilute HNO_3Aq , the solution is evaporated to a syrup, which is heated to $160^\circ\text{--}165^\circ$ for some hours, the product is thoroughly washed with boiling water, then dried over H_2SO_4 , and heated to $c\ 180^\circ\text{--}200^\circ$, until every trace of water is removed. Pure MnO_2 is thus obtained, exactly resembling *pyrolusite* (Gorgeu, *C R* 88, 796, Wright a Menke, *C J* 37, 45, cf. Schlösing, *C R* 55, 284, and Kuhlmann, *D P J* 211, 25). Even if the $\text{Mn}(\text{NO}_3)_2$ used contain a large quantity of KNO_3 , MnO_2 practically free from K_2O is obtained by this method.

Very many attempts have been made to obtain pure MnO_2 by ppn from Mn salts, e.g. by ppg with BrAq in presence of Na acetate, by passing Cl into an alkaline solution containing MnCO_3 in suspension, by reacting on a Mn salt solution with KMnO_4Aq , &c. The various methods have been examined by Gorgeu (*C R* 88, 796, *A Ch* [3] 66, 153), Guvard (*Bl* [2] 1, 89), Hannry (*C J* 33, 269, cf. Beilstein a Jawein, *B* 12 1530), Pickering (*C J* 35, 654), Vollhard (*A* 198, 318), Kesslet (*T* 18, part 1), Pattinson (*C J* 35, 365), Veley (*C J* 37, 581), Wright a Luff (*C J* 33, 504), and Wright a Menke (*C J* 37, 22). The outcome of the work is that pure MnO_2 cannot be obtained by any of the ppn methods, either the pp as $x\text{MnO} \cdot y\text{MnO}$, or, if all the Mn is present as MnO , the pp contains also K_2O or some other base besides H_2O . Vollhard's method—adding excess of KMnO_4Aq to MnSO_4Aq in presence of HNO_3 (exact quantities are given by V)—gave all the Mn as MnO accompanied by a small quantity of K_2O (c 3 p.c.), which could not be removed by washing (W a M, 1c).

Properties—A black, or brownish black, hard, crystalline powder. SG 5.02. Heated to moderate redness, Mn_2O_3 is formed, heated to whiteness, Mn_2O_3 remains (cf. *Mangano manganic oxide*, *Preparation*, p 182). MnO_2 is a conductor of electricity, it is strongly electro negative to the metals. Reacts with acids to form salts corresponding with MnO , with cold conc HClAq most probably forms MnCl_2 .

Reactions—1 Heated, gives Mn_2O_3 at moderate redness, and Mn_2O_4 at white heat—2 Heated in hydrogen, or carbon monoxide, is reduced to MnO , reduction in H begins at $c\ 190^\circ$, and in CO at $c\ 87^\circ$, when heated with carbon reduction begins at $c\ 390^\circ$ (Wright a Luff, *C J* 33, 518)—3 Heated with potassium chlorate, O is evolved and MnO_2 and KCl remain:

a little Cl is evolved, and at one stage of the change KMnO_4 is produced. The reaction between MnO_2 and KClO_3 probably produces KMnO_4 , Cl, and O, the KMnO_4 then decomposes to K_2MnO_4 , MnO_2 , and O, and the K_2MnO_4 reacts with Cl to form KCl , MnO_2 , and O. The following equations are given by McLeod as expressing approximately the various changes:

(1) $2\text{MnO}_2 + 2\text{KClO}_3 = 2\text{KMnO}_4 + \text{Cl}_2 + \text{O}_2$,
(2) $2\text{KMnO}_4 = \text{K}_2\text{MnO}_4 + \text{MnO}_2 + \text{O}_2$,
(3) $\text{K}_2\text{MnO}_4 + \text{Cl}_2 = 2\text{KCl} + \text{MnO}_2 + \text{O}_2$ (v McLeod, *C J* 55, 184, Hodgkinson a Lowndes, *C N* 59, 63, Fowler a Grant, *C J* 57, 272, Baudumont, *J Ph* [4] 14, 84, 161, Warren, *C N* 58, 247, Veley, *T* 1888 [1], 271, Spring a Prost, *Bl* 1889 340)—4 With hot conc sulphuric acid, MnSO_4 is formed and O evolved—5 With cold conc hydrochloric acid, MnCl_2 is very probably produced, on warming, Cl is evolved and MnCl_2 remains (cf. *Manganic chloride*, p 180)—6 Heated with sulphuric acid and oxidisable bodies, MnO acts as an oxidiser, e.g. $\text{H}_2\text{C}_2\text{O}_4$ is thus oxidised to CO_2 and H_2O —7 Not acted on by moderately dilute nitric acid alone, but in presence of an oxidisable body, $\text{Mn}(\text{NO}_3)_2$ and oxidised products are formed, e.g. with HNO_3 and HCl , Cl is evolved—8 Compounds of Mn O, with SeO_2 , were obtained by Laugier (*C R* 104, 1508), by heating ppd MnO_2 with selenious acid—9 With hydrogen peroxide and an acid, forms a salt of MnO and H_2O and evolves O, with hydrogen peroxide alone, O is evolved and the same quantity of MnO remains as was originally used (v Hydrogen peroxide, *Reactions* 11 and 19, vol II pp 723, 724)—10 Heated with magnesium chloride, MnCl_2 and MgO are formed and Cl is evolved—11 Fused with alkalis in presence of air or oxygen, manganates M^1MnO_4 , are formed (v Manganates under *Manganese*, oxyacids of, p 185).

12 MnO_2 combines with a number of basic oxides to form salts of the form $x\text{MO} \cdot y\text{MnO}_2$, known as *manganites*. According to Gorgeu (*A Ch* [3] 66, 153) MnO_2 decomposes neutral solutions of many salts of Ca, Ba, Ag, and Mn, making the solutions acid to litmus and combining with the bases. From dilute solutions of K_2CO_3 and Na_2CO_3 , MnO_2 withdraws and combines with 7 p.c. K_2O , and 4.1 p.c. Na_2O , respectively, according to Gorgeu, the *manganites* thus produced approximately correspond with the formula $\text{M}_2\text{O} \cdot 15\text{MnO}_2$. According to Jolles (*Chem. Zeitung*, 11, 1394) K_2MnO_4 is obtained, as a brown yellow solid, by mixing equivalent quantities of KMnO_4 and $\text{C}_2\text{H}_4\text{O}$. Wright and Menke (*C J* 37, 22) have examined the *potassium manganites* formed by ppg MnO_2 in presence of K salts, by passing Cl into $\text{K}_2\text{CO}_3\text{Aq}$ holding MnCO_3 in suspension, by adding MnSO_4Aq to KMnO_4Aq , &c., they conclude that the amount of K_2O ppd in combination with MnO_2 varies according to the relative masses of the reacting bodies, the temperature, the quantity of free acid present, &c., and that it tends to the maximum $5\text{M}_2\text{O} \cdot \text{K}_2\text{O}$. W a M failed to obtain $8\text{MnO}_2 \cdot \text{K}_2\text{O} \cdot 3\text{H}_2\text{O}$ described by Stigl a Morawski (*J pr* [2] 18, 91) as produced by acting on KMnO_4Aq with a reducing agent such as SO_2 , glycenn, or alcohol, they say that K_2O is ppd in combination with MnO_2 , but that the ratio of K_2O to MnO_2 varies much. Weldon (*C. N.* 20,

109) gave the formulae CaO MnO_2 and CaO 2MnO_2 to the *manganites* formed by oxidising $\text{MnO H}_2\text{O}$ by air in presence of lime. *Manganites* of the form MO 5MnO_2 , where $\text{M} = \text{Ca, Ba, Sr, Zn, and Pb}$, are described by Risler (*Bl* [2] 30, 110) as produced by heating KMnO_4 with slight excess of various metallic chlorides, and washing with water. By heating metallic chlorides with MnO_2 , and then adding MnCl_2 , Rousseau obtained *manganites*, which he classes as MO 5MnO_2 , MO MnO_2 , and 2MO MnO_2 (*C R* 101, 167, cf also Post, *B* 12, 1484, 1537, Rammelsberg, *B* 8, 233, Rousseau, *C R* 102, 425, 615, 103, 261, 104, 786, 1796). Various compounds of MnO with MnO_2 seem to exist, these may be regarded as *manganese manganites*, *v Oxydes intermediate between manganic oxide and manganese peroxide, infra*.

13 While MnO_2 reacts as an acidic oxide towards the oxides of the more positive metals, it also reacts as a basic oxide with some acids. The usual reactions of MnO_2 with acids are those of a basic peroxide (*v Reactions*, 3 to 6, *supra*). The salt MnO_2SO_4 is said by Fremy to be formed by carefully reacting on $\text{MnO}_2 \cdot x\text{H}_2\text{O}$ with conc H_2SO_4 , and allowing to stand in air (*C R* 82, 475). By adding MnSO_4 to a freshly prepared solution of PbO_2 in acetic acid, as long as PbSO_4 was pptd., Schönbein (*J pr* 74, 325) obtained a deep brownish red liquid, which had strongly oxidising properties, and from which MnO_2 separated on standing, or more quickly on boiling. Schönbein thought that this liquid contained an acetate of MnO_2 , but he did not succeed in isolating this salt.

HYDRATES OF MANGANESE PEROXIDE When approximately pure MnO_2 is pptd. by oxidising manganous salts in alkaline solutions, or by reactions between manganous salts and permanganates, or by decomposing KMnO_4aq by H SO_4 or HNO_3 , the pp always contains water, but it is very doubtful whether any definite, and fairly stable, hydrate of MnO_2 exists. When the process of formation results in ppn of all the Mn as MnO_2 , the composition of the pp approximates to $\text{MnO}_2 \cdot \text{H}_2\text{O}$, but this body loses water in dry air (*v* Wright & Menke, *C J* 37, 22). When the whole of the Mn is not pptd. as MnO_2 , the pp consists of compounds of the form $x\text{MnO}_2 \cdot y\text{MnO} \cdot z\text{H}_2\text{O}$ containing variable quantities of metallic oxides according to the conditions of formation. It appears to be possible to obtain hydrates which are stable for many hours within definite limits of temperature, but these hydrates are of the form $x\text{MnO}_2 \cdot y\text{MnO} \cdot z\text{H}_2\text{O}$ (*v* Velely, *C J* 37, 581, 41, 56).

References—The following papers contain the chief experiments bearing on the formation and composition of supposed hydrates of MnO_2 —Rammelsberg, *B* 8, 233, Fremy, *C R* 82, 1231, Van Bemmelen, *B* 13, 1466, Gorgeu, *A Ch* [3] 66, 154, *C R* 108, 948, Von Hauer, *W A B* 13, 453, Reising, *A* 103, 206, Böttcher, *J pr* 76, 235, Guyard, *Bl* 6, 81, Morawski a Stungl, *J pr* [2] 18, 90, 97, Volhard, *A* 193, 318, Suckow, *D P J* 177, 231, Wernicke, *P* 141, 116, Velely, *C J* 37, 581, 41, 56, Pickering, *C J* 35, 654, Wright & Luff, *C J* 33, 504, Wright & Menke, *C J* 37, 22, Franke, *J pr* [2] 86, 166, 451.

OXIDES INTERMEDIATE BETWEEN MANGANIC

OXIDE AND MANGANESE PEROXIDE These oxides belong to the general formula $x\text{MnO} \cdot y\text{MnO}_2$. The composition of the pp obtained by adding water to solutions of MnO , or Mn_2O_3 , in cold conc HClAq varies between $16\text{MnO} \cdot 5\text{MnO}_2$ and $36\text{MnO} \cdot 5\text{MnO}_2$ (Pickering, *C J* 35, 659). By passing Cl for a limited time into solution of Mn acetate, Velely obtained a pp approximating in composition to $5\text{MnO} \cdot \text{MnO} \cdot x\text{H}_2\text{O}$ (*C J* 37, 581, 41, 56, by heating this pp in a current of air, the compound $11\text{MnO} \cdot \text{MnO} \cdot \text{H}_2\text{O}$ was produced, and by heating the first compound in O , the body produced had the composition $23\text{MnO} \cdot \text{MnO} \cdot 2\text{H}_2\text{O}$. Wright & Menke (*C J* 37, 22) obtained a number of bodies $x\text{MnO}_2 \cdot y\text{MnO} \cdot z\text{H}_2\text{O}$ by various processes of oxidising manganous salts, and reducing permanganates, in every case, however, K O , or other alkali, was held in combination. Further accounts of these intermediate oxides, many of which were probably mixtures of the better defined oxides of Mn, will be found in the memoirs referred to under **HYDRATES OF MANGANESE PEROXIDE** (*v supra*), especially in the memoirs of Gorgeu.

MANGANFSE TRIOXIDE, Mn_2O_3 This compound is formed, in very small quantities, by slowly dropping a solution of KMnO_4 in cold conc H_2SO_4 (c f grams KMnO_4 in 100 cc H SO_4) on to dry Na_2CO_3 . The Na CO_3 is placed in a distilling flask surrounded by cold water. The flask is connected with a U tube filled with fragments of glass, and surrounded by a mixture of ice and salt, and this tube is connected with another U tube containing a little dilute $\text{H}_2\text{SO}_4\text{aq}$. As each drop of the green solution of KMnO_4 in H_2SO_4 falls on to the Na CO_3 , a pink cloud is formed, the cloud partly condenses in the first U tube, and part of it passes on and is dissolved in the H SO_4 in the second tube (Franke, *C J* [2] 36, 31, 166, *v* also Thorpe & Hambly, *C J* 53, 175). Only a very small quantity of MnO can be obtained. It appears as a reddish, amorphous, deliquescent mass. It slowly decomposes at ordinary temperatures, but is fairly stable if surrounded by ice and salt (*T a H*, l c). Mn_2O_3 is decomposed by water yielding HMnO_4aq and MnO_2 (*T a H*), according to Franke, H_2MnO_3 is produced, but quickly decomposes to MnO_2 , O , and HMnO_4 , and probably also $\text{H Mn}_2\text{O}_4$. Mn_2O_3 dissolves in conc H_2SO_4 , forming a green solution. Franke thinks this liquid contains $(\text{MnO}_2)_2\text{SO}_4$. Mn_2O_3 dissolves in KOH Aq , forming K_2MnO_4 . Mn_2O_3 liberates I from KI , and acts on Hg similarly to ozone (*T a H*).

MANGANESE HYPOXIDE, Mn_3O_4 , (*Permanganic anhydride*) This oxide was obtained by Thenard (*C R* 42, 382). Its composition was determined by Aschoff (*J pr* 81, 34). Pure KMnO_4 , free from Cl compounds, is added little by little to conc H SO_4 , *S G* 1845, kept cold by a freezing mixture. To the green solution thus obtained a few drops of water are added, when Mn_2O_3 slowly separates in dark redash-brown oily drops. If acid of the composition $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ (*S G* c 178) is used, oily drops of Mn_2O_3 are formed without addition of water. According to Franke (*J pr* [2] 86, 81), a solution of KMnO_4 in conc H_2SO_4 contains $(\text{MnO}_2)_2\text{SO}_4$, and this is decomposed by a little water, giving Mn_2O_3 and H_2SO_4 .

Terreil (*Bl* 1862 40) prepares Mn_2O_3 by dissolving $KMnO_4$ in well cooled H_2SO_4 , containing water in the ratio $H_2SO_4 : \frac{1}{2}H_2O$, placed in a stoppered retort, the neck of which passes into a glass balloon surrounded by a freezing mixture. Corks or organic material must not be used in any part of the apparatus. He heats the retort to $60^\circ-65^\circ$ (not over 70°), when purple red vapour is evolved and condensed to a thick greenish black liquid, which is Mn_2O_3 . Only a few drops of Mn_2O_3 can thus be prepared at a time. As soon as a certain quantity collects in the balloon, decomposition occurs, with slight detonation (v also Spiess, *J pr* [2] 1, 421).

P. Thenard (*J pr* 69, 58) describes Mn_2O_3 as a dark olive green liquid, with a smell recalling Cl compounds and ozone. Aschoff (*J pr* 81, 34) describes it as dark brownish red oily drops, which do not solidify at -20° . Mn_2O_3 slowly decomposes in air at ordinary temperatures, with evolution of O. It may be heated to $60^\circ-65^\circ$, under reduced pressure, without volatilising, at a somewhat higher temperature it is suddenly and violently decomposed to MnO_2 and O. Mn_2O_3 is very hygroscopic. It dissolves in water to form a purple liquid, probably containing $HMnO_3$. This liquid is slowly decomposed on warming into MnO_2 and O. Mn_2O_3 dissolves in cold conc H_2SO_4 , apparently with out decomposition, to form an olive green liquid (this liquid contains $(MnO_3)_2SO_4$ according to Franke, *J pr* [2] 36, 31). Mn_2O_3 is at once decomposed by contact with small quantities of MnO_2 , Ag O, or HgO (Aschoff, *l c*). Mn_2O_3 is a powerful oxidiser. It inflames paper or alcohol.

MANGANESE TETROXIDE (?) Franke (*J pr* [2] 36, 31, 166) states that a blue gas is obtained by leading air or CO_2 , saturated with water at $40^\circ-50^\circ$, over the green liquid formed by dissolving $KMnO_4$ in well cooled conc H_2SO_4 . To this blue gas he gives the formula MnO . Thorpe and Hamble repeated Franke's experiments (*C J* 53, 178), but failed to obtain any indications of the formation of a blue gas.

Manganese, oxyacids of, and their salts. Two series of salts derived from oxyacids of Mn are known—the *manganates* Mn_2MnO_4 and the *permanganates* $MnMnO_4$. The acid corresponding to the manganates, viz H_2MnO_4 , has not been isolated, but its anhydride MnO_3 is known. The anhydride of permanganic acid, viz Mn_2O_7 , is known, and the acid itself has also probably been isolated.

MANGANATES, M_2MnO_4 , derived from the hypothetical acid H_2MnO_4 . The anhydride of this acid, viz MnO_3 , is known. A solution of this oxide in water perhaps contains H_2MnO_4 , but it decomposes almost at once to $HMnO_3$ and MnO_2 (v *Manganese trioxide*, p 184). When an acid is added to solution of a manganate, the manganic acid produced at once decomposes to permanganic acid and MnO_2 . This change occurs even when CO_2 is passed into solution of a manganate. The manganates are isomorphous with the sulphates.

The fact that the product of fusing together pyrolusite, potash, and saltpetre dissolved in water to form a green liquid, which became blue, violet, and then red, on addition of much water, was known to Scheele. To the green substance Scheele gave the name '*Chameleon minerale*.'

Chevillot and Edwards, in 1817, showed that the green substance was a definite compound of potash with an acid of Mn (*A Ch* [2] 4, 287, 8, 337). Forchhammer (*Annals of Phil* 16, 310, 17, 150) and Fromherz (*P* 31, 677) investigated the manganates. Mitscherlich, in 1830, showed that two salts are obtained by the action of alkali on pyrolusite in presence of air or alkali nitrate (*P* 25, 287).

Manganates of the alkalis and alkaline earths are obtained by heating MnO_2 with KOH, $CaO.H_2O$, &c, to c 150° in absence of air, or to higher temperatures in presence of air, or by strongly heating any Mn salt with KOH, $CaO.H_2O$, &c, in presence of O or an oxidiser, e.g. $KClO_3$, K_2MnO_4 , and Na_2MnO_4 dissolve with out decomposition in water containing alkali. In pure water, $KMnO_4$ or $NaMnO_4$ is formed and MnO_2 ppt. Solutions of the alkali manganates are decolourised, with p.pn of MnO_2 , by easily oxidised bodies, e.g. SO_2 , As O_3 , H_2SAq , or ferrous salts. Ba and Sr manganates are in soluble in water.

Barium manganate $BaMnO_4$. A dark green powder. SG 4.85. Insol water. Unchanged in air, decomposed by acids. Prepared by calcining $Ba(NO_3)_2$ with MnO_2 , or by projecting finely powdered MnO_2 into a molten mixture of $KClO_3$ and $BaO.H_2O$, washing with hot water, and drying. By heating MnO_2 with $Ba(NO_3)_2$, $BaMnO_4$ is obtained as a green powder consisting of minute hexagonal crystals (Forchhammer, *Annals of Phil* 16, 130, 17, 150, Rosenstiehl, *J Ph* 46, 544, Schafarik, *J pr* 90, 16). The salt is also obtained by digesting $Ba(MnO_4)_2$ with $BaO.Aq$.

Didymium manganate $Dy_2(MnO_4)_3$. A black powder, insol water. Obtained by heating for 30 minutes 1 pt MnO_2 with 4 pts Dy_2NO_3 , and washing with water (Frerichs & Smith, *A* 191, 353).

Lanthanum manganate $La_2(MnO_4)_3$. Resembles the Dy salt, prepared similarly (*F a, S l c*).

Potassium manganate $KMnO_4$.

Formation—1 A mixture of equal parts of finely powdered MnO_2 and KOH is heated to bright redness in air, or in O, $3MnO_2 + 2KOH = K_2MnO_4 + Mn_2O_3 + H_2O$. $KMnO_4$ is formed by heating MnO_2 and KOH in absence of O to c 150° (Beketoff, *Bl* 1, 43), the reaction occurs in N at c 180° (Elliot & Storer, *P Am A* 5, 192). If the mixture is heated above 180° O must be present, because at c 190° K_2MnO_4 is decomposed with reformation of MnO_2 .—2 By boiling conc $KMnO_4$ with KOH.Aq; $2KMnO_4.Aq + 2KOH.Aq = 2K_2MnO_4.Aq + H_2O + O$ (Aschoff, *J pr* 81, 29). According to Thenard (*J pr* 69, 58), this reaction only occurs when the KOH contains some oxidisable substances, e.g. a little organic matter.—3 By long continued heating $KMnO_4$ to 240° , $2KMnO_4 = K_2MnO_4 + MnO_2 + O_2$ (Thenard, *l c*).—4 By fusing any oxide of Mn with KOH in presence of O, or an oxidiser such as $KClO_3$.

Preparation—2 pts KOH are dissolved in the smallest quantity of water, 1 pt $KClO_3$, and 2 pts very finely powdered MnO_2 are added, the mixture is dried, and then heated, nearly to redness, for a long time in a Pt dish, the fused mass when cold is treated with a little water,

the conc green solution is decanted, after standing until quite clear, and evaporated *in vacuo* over H_2SO_4 .

Properties and Reactions—Dark green crystals, isomorphous with K_2SO_4 and K_2CrO_4 . Soluble in water containing KOH without decomposition, dissolves in pure water with decomposition to $KMnO_4$ and MnO_2 . Dilute acids, even CO_2 , quickly decompose K_2MnO_4 , forming K permanganate and a manganous salt, e.g. with H_2SO_4 ,— $5K_2MnO_4 \cdot Aq + 4H_2SO_4 \cdot Aq = 2K_2MnO_4 \cdot Aq + MnSO_4 \cdot Aq + 3K_2SO_4 \cdot Aq + 4H_2O$. Heated in CS_2 , MnS , CO_2 , and polysulphides of K are formed (Muller, *P* 127, 404). Heated in a stream of water vapour, Mn_2O_3 , KOH, and O are produced.

$(2K_2MnO_4 + 2H_2O = Mn_2O_3 + 4KOH + 3O)$ By fusing MnO_2 with KOH in air, and then passing water vapour over the product, then again fusing the products together, and repeating these processes, O may be obtained from the atmosphere.

Sodium manganate $Na_2MnO_4 \cdot 10H_2O$. Obtained by long continued heating equal pts finely powdered MnO_2 and $NaNO_3$, boiling with water, filtering, and allowing to cool (Gentele, *J* pr 82, 58). Said to form colourless crystals, resembling Glauber's salt, and to dissolve in water with partial decomposition to form a green solution.

PERMANGANIC ACID AND PERMANGANATES The acid $HMnO_4$, or $H_2Mn_2O_8$, has probably been isolated, a series of salts derived from this acid is known. Permanganic anhydride, Mn_2O_7 , is a very unstable liquid, it dissolves in water to form $HMnO_4 \cdot Aq$, which slowly decomposes to MnO_2 and O. Permanganic acid and its salts readily part with O, and hence act as energetic oxidisers. The permanganates are isomorphous with the perchlorates $M'ClO_4$, they are purple red, all are soluble in water, the least soluble is the Ag salt. These salts are produced by the action of dilute acids, or of Cl, on the manganates, or by the reaction of several oxidisers, e.g. Pb_2O_3 and dilute $HNO_3 \cdot Aq$, on Mn salts—(Tamm, *J* 1872 910, Fresenius, *Fr* 11, 415, 425, Crum, *A* 60, 219, Gibbs, *Am S* [2] 14, 204, Chatard, *C N* 24, 196, Pichard, *C R* 75, 1821, Deshayes, *Bl* [2] 29, 541, Volhard, *A* 198, 354, Rose, *P* 105, 289). $KMnO_4$ is reduced to K_2MnO_4 by boiling conc $KMnO_4 \cdot Aq$ with potash (cf. POTASSIUM MANGANATE, *Formation* No 2, p 185). Solutions of permanganates are decomposed by $NH_3 \cdot Aq$ with separation of $xMnO_2 \cdot yMnO$, they are reduced to manganous salts by $HNO_3 \cdot Aq$, fairly conc $HCl \cdot Aq$, $SO_2 \cdot Aq$, $Na_2S_2O_4 \cdot Aq$, many organic compounds, &c. H_2SO_4 decomposes solid permanganates with separation of MnO_2 and evolution of O. Solutions of $HMnO_4$ and $KMnO_4$ absorb the green and yellow green rays of the spectrum, the absorption spectrum has been examined by Lecoq de Boisbaudran (*Spectres lumineux*, p 108). According to Vogel (*B* 8, 1534) $\frac{1}{10000}$ pt of Mn may be detected, in presence of Cu and Fe compounds, by boiling with P_2O_5 or Pb_2O_3 and dilute $HNO_3 \cdot Aq$ free from Cl compounds, and examining the absorption spectrum of the solution (of permanganate) produced.

Ammonium permanganate NH_4MnO_4 . Resembles $KMnO_4$, with which it is isomorphous, v sol water, decomposed by gently

heating. Prepared by rubbing together $AgMnO_4$ and $NH_4Cl \cdot Aq$ in the ratio $AgMnO_4$, NH_4Cl , filtering, and evaporating at the ordinary temperature over H_2SO_4 , also by decomposing $BaMnO_4$ by $(NH_4)_2SO_4$ (Böttger, *N R P* 25, 115).

Barium permanganate $BaMnO_4$. Small, hard, rhombic octahedra, almost black, with violet sheen. Prepared by adding excess of $H_2SiF_6 \cdot Aq$ to $KMnO_4 \cdot Aq$, filtering from $KSiF_6$ through asbestos, saturating with $BaO \cdot Aq$ containing $BaO_2 \cdot H_2$ in suspension ($BaCO_3$ should not be used as it causes ppm of MnO_2 , xH O), decanting from $BaSiF_6$, and evaporating (Rousseau a Brunesau, *C R* 93, 229). Böttger (*N R P* 25, 115) prepares $BaMnO_4$ by dissolving in water the product of the fusion of 2 pts KOH and 1 pt MnO_2 , filtering, and adding $BaCl_2 \cdot Aq$ until the green colour of the liquid disappears, he collects the violet blue pp, and washes it with cold water till the washings begin to appear reddish, he heats this pp, which is $Ba(MnO_4)_2$, with water, passes in CO_2 till the liquid is purple red, filters from MnO_2 , and evaporates.

Calcium permanganate $CaMnO_4 \cdot 5H_2O$. A crystalline, deliquescent mass, prepared by decomposing $AgMnO_4$ by $CaCl_2 \cdot Aq$, following directions given for obtaining NH_4MnO_4 (*v supra*).

Cobalt permanganate does not seem to have been isolated, but Klobb has prepared several luteo cobaltic permanganates, viz $Co_2(NH_4)_{12}(MnO_4)_6$, $Co(NH_4)_{12}Cl_4(MnO_4)_4$, $Co(NH_4)_{12}Br_4(MnO_4)_4$ (*C R* 103, 384, *Bl* [2] 48, 240).

Potassium permanganate $KMnO_4$.

Formation—1 By fusing together KOH and an oxide of Mn in the air or with $KClO_3$, dissolving the K_2MnO_4 in water, passing in CO_2 , filtering from MnO_2 , and evaporating.

$(3K_2MnO_4 \cdot Aq + 2CO_2 = 2KMnO_4 \cdot Aq + 2K_2CO_3 \cdot Aq + MnO_2)$ —2 By warming solution of a Mn salt with $KClO_3$ and $KClO_4 \cdot Aq$ —3 By melting MnO_2 with KHO , making a conc solution of the fused mass, adding saturated $MgSO_4 \cdot Aq$, and filtering.

$(3K_2MnO_4 \cdot Aq + 2MgSO_4 \cdot Aq = 2KMnO_4 \cdot Aq + 2K_2SO_4 \cdot Aq + 2MgO + MnO_2)$ (Tessie du Mothay, *D P J* 186, 231)—4 By passing Cl into a solution of the fused mass obtained as in 1 and 3, and evaporating (Stadeler, *J* pr 103, 107). $(2KMnO_4 \cdot Aq + Cl_2 = 2KCl \cdot Aq + 2KMnO_4 \cdot Aq)$

Preparation—A mixture of 2 pts KOH and 1 pt $KClO_3$ is melted in a thin sheet iron crucible, the crucible is removed from the lamp, and 2 pts very finely powdered and sifted MnO_2 are added, little by little, heating is then continued, with stirring, until the mass gets quite hard, the temperature is then raised for a short time to full redness, when cold, the mass is broken up, and boiled with so much water that no crystals separate on cooling (c 40 pts water for 1 pt $KClO_3$ used), a rapid stream of well washed CO_2 is passed into the boiling liquid until a drop placed on paper makes a red stain (showing no green at the edges), the outer part of which soon becomes brown. After cooling the greater part of the liquid is poured off, the rest is filtered (from MnO) through glass wool, and the whole is evaporated until a drop placed on a cold surface quickly deposits crystals.

After standing 12 to 24 hours the greater part of the KMnO_4 separates out, a little is obtained by further evaporating the mother liquor 100 grms pyrolusite give about 30 grms KMnO_4 (Böttger, *J pr* 90, 156, for modification of this method, v Grager, *J pr* 96, 169, Wöhler, *P* 27, 626, Gregory, *J Ph* 21, 312, Mitscherlich, *P* 25, 287, Elliot a Storer, *P Am* 4, 5, 192) Béchamp (*A Ch* [3] 57, 293) heats MnO_2 with KOH , and oxidises by passing O over the fused mass, he then dissolves in water, passes in CO_2 , and evaporates

Properties—Dark purple red, almost black, rhombic crystals, $a, b, c = 79523 \text{ 1 6478}$ SG 2.71 (Kopp) Isomorphous with KClO_4 , S at $15^\circ = 6.25$ (Mitscherlich) Decomposed by heat, giving K_2MnO_4 and O Pure conc KMnO_4Aq can be boiled without change, in presence of oxidisable bodies KMnO_4Aq is quickly reduced

Reactions—1 Heated to 240° , MnO_2 , K_2MnO_4 , and O are produced (Chevillat a. Edwards, *A Ch* [2] 4, 290) At higher temperatures αMnO yk O is formed (Rousseau, *C R* 104, 786)—2 Sulphuric or nitric acid separates HMnO_4 , which decomposes with evolution of O and ppn of MnO_2 , Mn_2O_3 , or αMnO , γMnO , with considerable excess of warm $\text{H}_2\text{SO}_4\text{Aq}$ or HNO_3Aq , MnSO_4 or $\text{Mn(NO}_3)_2$ is produced Cold conc H_2SO_4 dissolves KMnO_4 , forming a green liquid, from which a few drops of water cause separation of MnO , (cf *Manganese heptoxide*, p 181, v also *Manganese trioxide*, p 184)—3 Hydrochloric acid in excess forms MnCl_2 , and evolves Cl Dry HCl evolves Cl , and forms H_2O , HCl , Mn_2O_3 , $\alpha\text{H}_2\text{O}$, MnCl_2 , and probably Mn_2Cl_2 (Thomas, *C J* 33, 372)—4 Sulphuric acid and oxidisable bodies either separate MnO , or αMnO , γMnO , the oxidisable body being simultaneously oxidised, or if there be enough acid to prevent ppn of αMnO_2 , γMnO , MnSO_4 is formed With $\text{H}_2\text{C}_2\text{O}_4$ and H_2SO_4 , CO_2 and H_2O (besides K_2SO_4 and MnSO_4) are produced (cf Berthelot, *A Ch* [5] 21, 176, Harcourt, *C J* [2] 5, 460, Jones, *C J* 33, 95) Harcourt (*lc*) represents the reaction thus

Jones (*lc*) says that H_2O , K_2CO_3 , and MnCO_3 are at first produced on adding KMnO_4Aq to $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$, and that further addition of KMnO_4Aq forms K_2CO_3 , pppts Mn_2O_3 , and evolves CO_2 and O Alcohol gives Acetate and a pp containing MnO_2 , MnO , and K_2O , glycerin gives a similar pp and forms K_2CO_3 (Morawski a Stingl, *J pr* [2] 18, 78, cf Berthelot, *lc*)—5 According to Aschoff (*J pr* 81, 29) conc KMnO_4Aq is reduced to K_2MnO_4 by boiling with potash solution ($2\text{KMnO}_4\text{Aq} + 2\text{KOH}\text{Aq} = 2\text{K}_2\text{MnO}_4\text{Aq} + \text{H}_2\text{O} + \text{O}$), Thenard (*J pr* 69, 58) says that this action does not occur unless traces of oxidisable substances, e.g. organic matter, are present—6 KMnO_4Aq acidified by H_2SO_4 reacts with hydrogen peroxide to form H_2O , O , and MnSO_4 At low temperatures, c 12° , the KMnO_4 is decolourised, but O is not evolved, according to P Thenard (*C R* 75, 177), Berthelot (*A Ch* [5] 21, 176) thinks that H_2O_2 (?) is formed (v also Swietrowski, *A* 141, 205, Aschoff, *P* 111, 217)—7 KMnO_4Aq is decomposed with separation of MnO_2 , Mn_2O_3 , or αMnO , γMnO , by ammonia (Clodé a Guignet,

C R 47, 710, Wöhler, *A* 136, 256, Wanklyn a Gamgee, *C J* [2] 6, 25, Tamm, *C N* 25, 47), by hydrogen (Jones, *C J* 33, 96, Wanklyn a Cooper, *P M* [5] 6, 288), by phosphine, arsine, and stibine (Jones, *lc*, Schobig, *J pr* [2] 14, 289, Parsons, *C N* 1877 236), by chlorine dioxide (ClO_2) (Furst, *A* 206, 75)—8 With potassium sulphocyanide, K_2SO_4 and KCN are produced (Morawski a Stingl, *J pr* [2] 18, 78)—9 Sodium thiosulphate in boiling solution is wholly oxidised to Na_2SO_4 by fairly conc KMnO_4Aq , if the KMnO_4Aq is very dilute from 1 to 2 p.c. $\text{Na}_2\text{S}_2\text{O}_4$ remains (Glaser, *M* 7, 651)

Combination—From conc mixed solutions of KMnO_4 and K_2MnO_4 , the salt $\text{K}'\text{MnO}$, K_2MnO , separates in small, six sided, monoclinic tablets (Gorgeu, *J pr* 80, 123)

Sodium permanganate $\text{NaMnO}_4 \cdot 3\text{H}_2\text{O}$ Formed similarly to KMnO_4 , or by the reaction between AgMnO_4 and NaClAq V sol water, and hence obtained in crystals with difficulty

Silver permanganate AgMnO_4 Monoclinic crystals S 91 in cold water Obtained by mixing conc warm KMnO_4Aq with AgNO_3Aq , and allowing to cool (Dewar a Scott, *P* 35, 44) Klobb (*C R* 103, 384) obtained $\text{AgMnO}_4 \cdot 2\text{H}_2\text{O}$, by saturating KMnO_4Aq with NH_3 , and then adding an equivalent quantity of AgNO_3

Permanganates of copper, didymium (Freichs a Smith, *A* 191, 354), **lanthanum** (F a S, *lc*), **lead**, **lithium**, **magnesium**, **strontium**, and **zinc**, have been isolated

Permanganic acid, HMnO_4 The solution obtained by decomposing powdered $\text{Ba(MnO}_4)_2$ by an exactly equivalent quantity of $\text{H}_2\text{SO}_4\text{Aq}$, contains this acid Hunefeld (*Schweigger's Jahrb der Chem und Phys* 30, 133) says that the acid can be obtained, in indigo like crystals, by washing $\text{Ba(MnO}_4)_2$ with hot water, whereby it is decomposed to MnO and BaMnO_4 , filtering, adding exactly enough phosphoric acid to decompose the Ba salt, heating to 60° – 100° , filtering, and evaporating at a low temperature (No analyses are given)

Manganese, oxychlorides of Several oxy chlorides of Mn appear to exist, but they have not been satisfactorily examined P de Saint Gilles (*C R* 55, 329) says that $\text{MnCl}_2 \cdot 3\text{MnO}_2$ is formed as a black powder, resembling MnO_2 , by heating to 280° , in a partially closed vessel a mixture of MnCl_2 and NaNO_3 Gorgeu (*A Ch* [6] 4, 515) obtained an oxychloride, to which he provisionally assigned the formula MnCl MnO by heating MnCl_2 in water vapour According to Aschoff (*J pr* 81, 29) the gas which Dumas obtained by adding pieces of fused KCl or NaCl to a mixture of KMnO_4 and conc H_2SO_4 , and which he said was MnCl_2 , is probably an oxy chloride having the composition MnOCl

Manganese oxyfluoride of According to Nicklès (*C R* 65, 107) the compounds MnOF KF and $\text{Mn}_2\text{OF}_2 \cdot 2\text{HF}$ are ppd, when solution of MnO_2 in ethereal HCl is poured into boiling KFAq or NaFAq Christensen (*J pr* [2] 30, 57), however, asserts that the double compound obtained as described above is MnOF_2

Manganese, oxysulphide of The compound MnO MnS is said to be formed, by Arfvedson (*P* 1, 50), by heating MnSO_4 in H_2 , it is a green solid, which dissolves in acids with evolution of H_2S , heated in air it burns to Mn_2O_3

Manganese, phosphides of Several compounds of Mn with P have been described. Mn_3P an amorphous powder, S G 494, obtained by heating Mn and P together to low redness (Schrötter, *J pr* 51, 386). Also formed, according to H. Rose, by heating $MnCl_2$ in PH_3 . By heating Mn pyrophosphate mixed with sugar-charcoal, in a crucible filled up with charcoal, Struve (*J pr* 81, 321) obtained a brittle substance resembling pig iron, the composition of which varied between Mn_3P_2 and Mn_2P . Merkel and Wöhler (*A* 86, 371) obtained a crystalline, greyish, regulus, S G 595, by heating together 10 parts MnO_2 , 10 parts well burnt bones, 5 parts quartz sand, and 3 parts lamp black. The composition agreed with the formula Mn_3P_2 , but as part was soluble, and part insoluble, in $HClAq$, they regarded the substance as a mixture of two phosphides, Mn_3P_2 (soluble in $HClAq$) and Mn_2P_2 (insoluble in $HClAq$).

Manganese, salts of Compounds obtained by replacing the H of acids by Mn. Mn forms two series of salts: *manganous salts*, MnX_2 , and *manganic salts*, Mn_2X_3 , $X = NO_3$, ClO_3 , $\frac{1}{2}SO_3$, $\frac{1}{2}PO_3$, &c. One or two salts of the form MnX ,—e.g. $Mn(SO_4)_2$ —are also said to exist. The manganous salts are considerably more stable than the manganic salts. A number of double salts of manganic sulphate are known, those with the alkali sulphates are alums, e.g. $Mn_2(SO_4)_3 \cdot K_2SO_4 \cdot 24H_2O$. The manganous salts form a fair number of double salts and a few basic salts. The chief salts of Mn are the following: *antimonates*, *arsenates* and *arsenites*, *borate*, *carbonates*, *chlorate* and *perchlorate*, *chromates*, *ferric* and *ferro cyanides*, *iodate*, *molybdate*, *nitrate* and *nitrites*, *phosphates* and *phosphites*, *selenates* and *selenites*, *sulfates*, *sulphates* and *sulphites*, *thiosulphate*, *tungstate*, *vanadate* v **CARBONATES**, **NITRATES**, **SULPHATES**, &c.

Manganese, selenide of Said to be produced in combination with H_2O as a red powder, decomposed in air, by adding an alkali selenide solution to solution of a manganous salt.

Manganese, silicides of Mn and Si combine when heated together (Troost & Hautefeuille, *C R* 81, 264). Silicides of Mn, containing from 6.5 to 13 p.c. Si, have been obtained by Wohler (*A* 106, 54) by fusing together MnF_3 , Na, K silicate, and cryolite, or $MnCl_2$, $2NaCl$, CaF_2 , and K silicate, or $MnCl_2$, CaF_2 , K_2SiF_6 , and Na. These silicides form hard, brittle masses, they dissolve in $HClAq$ with evolution of H and SiH_4 .

Manganese, silicofluoride of. $MnSiF_6 \cdot 6H_2O$. Hexagonal crystals, $a = 1.515$, S G at $17.5^\circ = 1.9038$ (Stolba, *C C* 1893 292). Formed by dissolving $MnCO_3$ or MnF_2 in H_2SiF_6Aq , and evaporating. When heated, the crystals give off water, and then SiF_4 , and leave MnF_2 (Berzelius).

Manganese, sulphides of Two sulphides are known, MnS and Mn_2S_3 .

Manganous sulphide, MnS Occurs native, as *manganese blende*, in hexagonal crystals, S G 895. Produced by heating together MnO or $MnCO_3$ and S, not by heating S with Mr. Also formed by heating Mn in CS_2 (Gautier & Hallopeau, *C R* 108, 806), also by heating various Mn compounds in H_2S (Carnot, *Bl* [2] 32, 162). Sidot (*J* 1868 229) obtained MnS in hexagonal crystals by heating the amorphous substance in a stream of H_2S . MnS is pptd from solutions of

Mn salts by NH_4S in PH_3 , as a pale buff coloured amorphous solid, which quickly oxidises in air, if this ppt is rapidly dried and then warmed in H_2S , pure MnS is obtained. MnS is a greenish solid, decomposed by weak acids, e.g. acetic acid, with evolution of H_2S . Heated in air, SO_2 is evolved and Mn_2O_3 remains (P. W. Hofmann, *D P J* 181, 364). Heated in H_2O vapour, H_2S and H are given off and Mn_2O_3 is formed. MnS is slowly decomposed by Cl with formation of $MnCl_2$ and S_2Cl_2 .

There appear to be two forms of MnS obtainable by pptn from Mn salts by NH_4S , sulphide the ppt from conc. $MnCl_2Aq$ or $MnSO_4Aq$ is rose coloured, if NH_4Cl is present the ppt is greenish and consists of small 8 sided plates. The green sulphide is not produced when K_2S or Na_2S is used as pptant (Fresenius, *J pr* 82, 265; Muck, *Z* 1869 580; de Clermont & Guyot, *Bl* 27, 353; Geuther, *Z* 1865 347). The rose coloured sulphide is said to be changed to the green sulphide by heating with a little water, but it may be heated to 305° with much water without changing. The change from rose to green is accomplished by heating with NH_4Aq to 250° in a closed tube, and the reverse change by heating in NH_3 gas. The rose sulphide is not changed by heating alone to 250° but in presence of H S the green sulphide is formed at 220° (De C & G, *l c*). The green sulphide is thought by Muck to be an oxysulphide of Mn.

Double compound, $3MnS \cdot K_2S$ Obtained by heating a mixture of 1 pt dry $MnSO_4$, $\frac{1}{4}$ pt lamp-black, and 3 pts K_2CO_3 and S, and treating the fused mass with water, the compound remains insoluble in water, forming small lustrous dark red tablets (Voelcker).

MANGANIC SULPHIDE, Mn_2S_3 Occurs native as *hauertite*, in large, brown black, lustrous, regular octahedra, S G 3463. Said to be obtained as a red amorphous powder, by heating $MnSO_4Aq$ with solution of K polysulphides to 160° – 180° in a closed tube (Senarmont, *J pr* 51, 385). Not changed in air, decomposed by acids.

Manganese, sulphocyanide of, v vol 11 p 850 M M P M

MANGANITES Salts in which MnO_2 acts as the acidic radicle, v *Manganese peroxide*, *Reactions* 12, under **MANGANESE**, *Oxides and hydrated oxides of*, p 183.

MANGANOCYANIDES v vol 11 p 342

MANGOSTIN $C_{20}H_{22}O_5$ [α 190°] Contained in the husk of the fruit of *Garcinia mangostana*. The dry husks are boiled with water to extract tannin, then treated with hot alcohol, and the alcoholic extract left to evaporate. The mangostin which is deposited is dissolved in alcohol and pptd by lead subacetate. The ppt is decomposed by water and the mangostin finally crystallised from dilute alcohol (Schmid, *A* 93, 853). Thin golden laminae without taste or smell. Insoluble in water, v sol alcohol and ether. Warm dilute acids dissolve it without alteration. Hot conc. HNO_3 gives oxalic acid. Alkalis dissolve it with yellowish brown colour. Reduces chloride of gold solution. $FeCl_3$ gives a dark greenish black solution, decolourised by acids. Its solution is not pptd by any metallic salt except lead subacetate— $(C_{20}H_{22}O_5) \cdot 5PbO$ (dried at 100°), pptd by adding alcoholic lead acetate and ammonia to an alcoholic solution of mangostin.

MANNITE $C_6H_{12}O_6$

$CH_2(OH)CH(OH)CH(OH)CH(OH)CH(OH)CH_2(OH)$

Occurrence—Discovered by Proust (*A Ch* [1] 57, 143) Occurs to the extent of 30 to 60 p.c. in manna, the dried juice which exudes from the manna ash (*Fraxinus Ornus*) Mannite occurs in many other plants, e.g. the roots of *Aconitum napellus*, celery, *Apium graveolens*, *Meum athamanticum*, *Evanthe crocata*, *Polypodium vulgare*, *Scorzonera hispanica*, and *Triticum repens*, and in the root bark of *Tunica granatum* Mannite also occurs in the bark of *Cinnella alba* (8 p.c.), and of *Fraxinus excelsior*, in the leaves and young twigs of *Syringa vulgaris*, in the leaves of *Ligustrum vulgare* and of *Cocos nucifera*, and in the fruit of *Laurus Persca* and of *Cactus opuntia* Mannite also occurs in *Laminaria saccharina*, in olives, and in several fungi, e.g. *Lactarius vellereus*, *L. tupsis*, *L. pyrogalus*, and *L. pallidus* *Agaricus integer* contains 20 p.c. of its dry substance It also occurs in the cambium layer of *Conifera* (Payen, *A* 12, 60, Meyer a. Reiche, *A* 47, 234, Stenhouse, *A* 51, 349, Knop a. Schmedemann, *A* 49, 293, Dopping a. Schlossberger, *A* 52, 117, Muntz, *C R* 76, 619, 82, 210, Smith *J* 1850, 335, Roussin, *J* 1851, 550, Ludwig, *J* 1857, 503, De Luca, *J* 1861, 740, 1862, 505, Thorner, *B* 12, 1635, Reinsch, *J* 1863, 612, Bouquelot, *C R* 108, 568, Kiehler, *M* 7, 410)

Formation—1 In the lactic fermentation of sugar (Liebig, *J* 1847, 466, Pasteur, *J* 1857, 511, Diagenдорff, *Ar Ph* [3] 15, 47)—2 In the viscous fermentation of sugar, 100 pts of sugar yielding 51 pts mannite and 46 pts gum (Pasteur, *J* 1861, 728)—3 In the spontaneous fermentation of the juice of the sugar cane in tropical climates (Maicano, *C R* 108, 955)—4 By reducing glucose, levulose, or invert sugar with sodium amalgam (Linnemann, *A* 123 136, Dewar, *P M* [4] 39, 345, Bouchardat, *Bl* [2] 16, 38, Krusemann *B* 9, 1465, Scheibler, *B* 16, 3010)—5 By reducing mannose (L. Fischer, *B* 21, 1808), or 'gluco-one' (L. Fischer, *B* 22, 94), with sodium amalgam—6 From the dilactone of meta saccharic acid by treating with water and sodium amalgam (3 p.c.), acidifying with H_2SO_4 (Kilian, *B* 20, 2714, v. LÉVO-MANNITE, *infra*)

Preparation—1 Manna is extracted with boiling dilute alcohol, and the crystals which separate on cooling are recrystallised from water—2 Manna (2 pts) is boiled with water (1 pt) after addition of a little white of egg The crystals which separate from the filtrate are boiled with water (6 pts) to which some animal charcoal has been added, and the filtrate is allowed to crystallise (Ruspin, *A* 65, 203)

Properties—Needles or four sided prisms ∇ sol water, ∇ al sol alcohol, insol ether An aqueous solution, does not become syrupy on

spontaneous evaporation (difference from sugar) Only slightly sweet to the taste It has little, if any, action on light, but if borax be added to the solution it becomes dextrorotatory Thus in a 10 p.c. solution containing 12.8 g borax $\alpha = +22.5^\circ$, so that $[\alpha]_D = c + 225^\circ$ (Vignon, *A Ch* [5] 2, 493, *C R* 77, 1191, Muntz a. Aubin, *C R* 83, 1213, Pasteur, *C R* 77, 1192, Bouchardat, *C R* 80, 120, 84, 34) Arsenic acid slowly develops levorotation in a solution of mannite Salts of the alkalis and alkaline earths develop dextrorotation Free alkalis render the solution levorotatory A solution containing 8 g mannite and 8 g NaOH in 100 c.c. gives $\alpha = -3.4^\circ$, so that $[\alpha]_D = -42^\circ$ A solution of 12 g mannite and 4 g sodium tungstate made up to 100 c.c. shows $\alpha = +0.40'$ (Klein, *C R* 89, 484) These rotations vary with the amount of dissolved substances The mannite may be recovered from these solutions without having undergone any change in optical properties Mannite renders a borax solution acid, forming boric acid and sodium metaborate (Dunstan, *Ph* [3] 13, 257, 14, 41, Lambert, *C R* 108, 1016) Mannite does not reduce Fehling's solution It hinders the ppn of ferric and cupric salts by potash It is not turned brown by boiling KOH aq With a solution of ammonio sulphate of copper it gives a blue pp, sol in ammonia, forming a blue solution which is not affected by boiling (Guignet, *C R* 109, 528, 645) Mannite does not reduce boiling solutions of silver or mercurous nitrates, of $HgCl_2$, or of chloride of gold, but it reduces AgO and silver acetate (Hirzel, *A* 131, 50) When alcohol is added to a solution of mannite mixed with lime, strontia, or baryta water, pps $(C_6H_{12}O_6)_2CaO$, $(C_6H_{12}O_6)_2SrO$, and $(C_6H_{12}O_6)_2BaO$ are formed (Hirzel, *A* 131, 50, cf Ubaldini, *A Ch* [3] 57, 213) Ammoniacal lead acetate gives a pp On adding to an aqueous solution of mannite (1 mol) and of lead nitrate (2 mols) sufficient ammonia to neutralise two thirds of the nitric acid present in the salt, a voluminous white pp separates, which, if filtered off and dried over calcium chloride, forms a white crystalline powder $C_6H_{12}O_6.Pb(NO_3)_2.2H_2O$, S 110 at 14° , decomposing with explosion on heating, and separated into its constituents on long boiling with water and by carbonic anhydride with formation of lead carbonate (Smolka, *M* 6, 198)

Reactions—1 Mannite begins to sublime at c 200°, in a sealed tube it is unaltered at 250° At 280° it splits up into water and mannitan $C_6H_8O_6$ When distilled *in vacuo* it yields isomannosan $C_6H_{10}O_6$ —2 A mixture of HNO_3 and H_2SO_4 forms the nitrate, so called 'nitro mannite' (Flores Domonte a. Menard, *J* 1847, 1145)—3 Nitric acid oxidises it to saccharic, racemic, and oxalic acids, no mucic acid being formed (Backhaus, *J* 1860, 522, Carlet, *J* 1861, 367)—4 Boiling HIAq gives sec-hexyl iodide (Wanklyn a. Erlenmeyer, Domac, *M* 2, 309, cf Le Bel a. Wassermann, *C R* 100, 1589)—5 Boiling conc HCl aq slowly forms mannitan—6 Potash fusion yields formic, acetic, and propionic and oxalic acids and acetone (Gottlieb, *A* 52, 122)—7 On oxidation with $KMnO_4$ in alkaline solution it gives oxalic acid, formic acid, a little tartaric acid, a sugar which reduces Fehling's solution, and erythric acid $C_6H_8O_6$, which forms

the salts CaA' , 2aq, BaA' , 2aq, and $\text{C}_2\text{H}_5\text{BaO}$, 2aq (Hecht a Iwig, *B* 14, 1760, 19, 468, cf Pabst, *C* R 91, 728, who states that he obtained a dibasic acid $\text{C}_2\text{H}_2\text{O}_5$, which he names dioxyisoelectric acid) — 8 *As* and *platinum black* yield mannitic acid $\text{C}_2\text{H}_2\text{O}_5$, and mannitose $\text{C}_2\text{H}_2\text{O}_5$ — 9 MnO_2 and H_2SO_4 give formic acid and acrolein (Baokhaus) — 10 When mannite (2 pts) is heated with 80 p.c. formic acid (5 pts) for 8 hours a mixture of formyl derivatives of mannitan appears to be formed. This mixture yields on distillation CO , CO_2 , isomannide $\text{C}_2\text{H}_2\text{O}_5$, a liquid $\text{C}_2\text{H}_2\text{O}_5$ (?) (157° at 17 mm) and a liquid $\text{C}_2\text{H}_2\text{O}$ (108°), *S* G $\frac{1}{2}$ 9396, $[\alpha]_D = -168^\circ$, almost insol water, and smelling like a carbamine and mustard oil (Fauconnier, *C* R 100, 914, cf Henninger, *B* 7, 264) — 11 Distillation with *oxalic acid* yields formic acid, a formyl derivative of mannite or of mannitan being probably first formed (Lorin, *Bl* (2) 24, 437) — 12 *Electrolysis* of a solution of mannite acidulated by H_2SO_4 yields hydrogen, CO_2 , CO , oxygen, tri oxy methylene (? formic paraldehyde or mannitose), formic acid, oxalic acid, and a small quantity of an acid whose calcium salt is $\text{C}_2\text{H}_2\text{CaO}_2$, 2aq. This acid having reducing properties may be

(Rénard, *A Ch* [5] 17, 316) — 13 PCl_5 gives tetra chloro-hexamine (Bell, *B* 12, 1273) — 14 PI_2 forms methylene iodide (Butlerow, *A* 111, 247) — 15 *Organic acids* (e.g. acetic and butyric) heated with mannite at 200° form alkyl derivatives of mannitan — 16 Mannite heated with *water* suffers no change below 280°, but at that temperature a viscid product is got containing 'mannitic ether' $\text{C}_2\text{H}_2\text{O}_5$, $[\alpha]_D = -5.6$ and 'mannitone', a crystalline isomeride of mannitan. Both bodies are reconverted into mannite by heating with water at 295° (Vignon). — 17 Mannite does not react when heated with acetic, valeric, or benzoic aldehydes (Lochert, *A Ch* [6] 16, 65). But when *acetic aldehyde* is passed into a solution of mannite in H_2SO_4 or HClAq the aldehyde is absorbed and there is formed a compound crystallising in needles [174°], insol cold water *S* 1 at 95°. It is sl sol cold, v sol hot, alcohol. Boiling dilute (2 p.c.) H_2SO_4 resolves it into aldehyde and mannite. Paraldehyde gives the same compound. When a mixture of acetic and benzoic aldehydes is used the above product is formed first (Meunier, *C* R 103, 408) — 18 When a mixture of mannite (10 g), absolute alcohol (20 g), and fused ZnCl_2 (5 g) is saturated with HCl , left for two days, and then mixed with benzoic aldehyde, there is formed 'tribenzoic mannitoid' $\text{C}_2\text{H}_2\text{O}_5(\text{C}_6\text{H}_5\text{O})_3$, [207°]. This crystallises from benzene, and is insol water, sl sol alcohol. It is not affected by boiling alcoholic KOH , but dilute H_2SO_4 yields mannite and benzoic aldehyde (Meunier, *C* R 106, 1425, 1732). A solution of mannite in HClAq or H_2SO_4 also reacts with benzoic aldehyde (Meunier, *C* R 107, 910) — 19 A solution of mannite in alcohol containing ZnCl_2 and saturated with HCl reacts with BaCl_2 forming di-benzoyl mannide $\text{C}_2\text{H}_2\text{O}_5(\text{OBz})_2$, [152°] (Meunier, *C* R 107, 346) — 20 *Valeric aldehyde*, ZnCl_2 and HCl convert mannite in alcoholic solution into $\text{C}_2\text{H}_2\text{O}_5(\text{C}_4\text{H}_9\text{O})_2$, which is deposited as silky needles [91°] (Meunier) — 21 Not fermented by yeast. In contact with water, chalk, and cheese at 40° it gives

alcohol, carbonic, lactic, butyric, and acetic acids, and hydrogen, but no sugar or glycerin (Berthelot, *J* 1856, 664). When the fermentation is induced by a slit testicle a fermentible sugar is produced. Upon fermentation by Schizomycetes in presence of CaCO_3 and ammonium phosphate there is formed alcohol, *n* butyl alcohol, butyric, lactic, acetic, hexoic, and succinic acids (Fitz, *B* 10, 281, 11, 43). *Bacillus butyricus* gives similar products. Under other conditions formic acid is among the products of fermentation (Fitz, *B* 11, 1895, 15, 876, 16, 845) — 22 Heating with phenyl cyanate forms $\text{C}_2\text{H}_2(\text{OH})(\text{O CONHPh})$, [260°] (Tessmer, *B* 18, 968).

Pentanitrate $\text{C}_2\text{H}_2(\text{ONO})_2\text{O}$ *Pentanitroxyl derivative* [79°] *S* 2 at 60° *S* (alcohol, *S* G $\frac{1}{2}$ 150 at 12.8° *S* (ether) 130 at 9° *S*). Formed, together with nitro mannitan, by passing NH_3 into an ethereal solution of the hexanitrate (Tichanovitch, *J* 1864, 582). Long needles. Dextrorotatory. Explodes when struck, and also, more feebly, when heated. Ammonium sulphide reduces it to mannite.

Hexanitrate $\text{C}_2\text{H}_2(\text{ONO})_2\text{O}$ *Nitro mannite* Mol w 452 [113°] (Socloff) *S* G $\frac{1}{2}$ 1604 *S* (alcohol of *S* G $\frac{1}{2}$ 81) 3 at 12.8° *S* (ether) 5 at 9° (Tichanovitch) $\alpha = +12.4$ in a 5 p.c. solution, so that $[\alpha]_D = +400^\circ$ (Muntz a Aubin). Prepared by treating mannite (1 pt) with HNO_3 (5 pts of *S* G 1.5) at 0°, and adding H_2SO_4 (10 pts). The product is collected on a filter, washed with water and aqueous Na_2CO_3 , and recrystallised from alcohol (Domont a Menard, *J* 1847, 1145, Sobrero, *A* 64, 397, Strecker, *A* 73, 62, Socloff, *J* R 11, 136). Beautiful white needles, insol water, sol alcohol and ether. Explodes violently on being struck — it also explodes when suddenly heated, but if carefully heated it may be decomposed without explosion. Ammonium sulphide converts it into mannite (Dessaignes, *A* 81, 251). Iron and acetic acid and HIAq also convert it into mannite (Béchamp, *A Ch* [3] 46, 354, Mill, *J* 1864, 584). NH_3 passed into its ethereal solution forms crystalline $\text{C}_2\text{H}_2\text{O}(\text{NH}_3)_2$ (Tichanovitch).

Di sulphuric acid $\text{C}_2\text{H}_2(\text{SO}_3\text{H})(\text{OH})_2$. From mannite and conc H_2SO_4 (Favie, *B* 25, 560). The free acid is decomposed by boiling water. It gives no pp with BaCl_2 or CaCl_2 — $\text{Pb}_2\text{C}_2\text{H}_2\text{O}_5\text{O}_{12} \cdot 2\text{PbO}$ insoluble pp.

Tri sulphuric acid $\text{C}_2\text{H}_2(\text{SO}_3\text{H})_3(\text{OH})$. From mannite and conc H_2SO_4 (Knop a Schnedermann, *A* 51, 136). Both the acid and its salts are decomposed by water into mannite and H_2SO_4 — $\text{Na}_3\text{A}'''$ — $\text{K}_3\text{A}'''$ deliquescent gummy mass, insol alcohol — $\text{Ba}_3\text{A}'''$ crystal line powder, sol water, insol alcohol — $\text{Pb}_3\text{A}'''$ amorphous deliquescent mass.

Tetra sulphuric acid $\text{C}_2\text{H}_2(\text{SO}_3\text{H})_2(\text{OH})_2$ $[\alpha]_D = +9^\circ$. Obtained when, in the preparation of the hexa sulphuric acid, the neutralisation with BaCO_3 is delayed for two days — Ba_4A^{IV} .

Hexa sulphuric acid $\text{C}_2\text{H}_2(\text{SO}_3\text{H})_6$. $[\alpha]_D = +24^\circ$. Formed by adding mannite in small portions to chloro sulphuric acid (ClSO_3H). The product is dropped upon ice, and the ice cold solution neutralised with BaCO_3 — Ba_6A^{VI} 5aq. When alcohol is added to its solution this salt is thrown down as an oil, which

presently changes to a crystalline mass insol water. The other salts are very soluble, and do not behave thus (Claesson, *J pr* [2] 20, 10).

Boric acid When mannite (4 pts) is heated with boric acid (3 pts) for eight hours at 145°, and the product is dissolved in water and neutralised by BaCO₃, a filtrate is obtained which deposits barium borate on evaporating, after which alcohol gives a pp which, when dried at 100°, has the composition (C₆H₇B₂O₈) Ba (Klein, *Bl* [2] 29, 363).

Hexa acetyl derivative C₆H₇(OAc)₆ [119°] [α]_D = +18° (Bouchardat, *C R* 84, 34). From mannite (18 pts) and Ac₂O (80 pts) at 180°, with or without addition of a little ZnCl₂ (Bouchardat, *A Ch* [5] 6, 107, Schutzenberger, *A* 160, 94, Franchimont, *B* 12 2059). Limit of etherification from mannite (1 mol) and HOAc (6 mols) 26.4 (Menschutkin, *B* 13, 1814). Trimetric crystals (from HOAc). Insol water, cold alcohol, and ether, sl sol hot alcohol. Dextrorotatory. May be sublimed in a current of CO.

Penta benzoyl derivative C₆H₇(OBz)₅(OH) [c 80°]. From mannite (3 g), water (15 g), BzCl (20 g), and NaOHAq. The product is extracted with ether (Skraup, *M* 10, 391). Amorphous mass.

Hexa benzoyl derivative C₆H₇(OBz)₆ [149°]. From the preceding and BzCl. Crystalline grains, v sl sol alcohol.

Mannite dichlorhydrin C₆H₇(OH)₂Cl₂. *Di chloro tetra oxy heane* [171°] S 4.5 at 14° [α]_D = -3.7. Formed by heating mannite (1 pt) with conc HClAq (6 pts) at 100° for eight hours (Bouchardat, *C R* 75, 1187, 76 1550, *Bl* [2] 19, 199). Formed also by heating isomannide with fuming HClAq at 100° in sealed tubes (Fauconnier, *Bl* [2] 41, 119). Prepared by heating mannite (1 pt) with fuming HClAq (10 pts) at 106°, evaporating at low temperatures, dissolving the crystals in water, filtering the solution through animal charcoal, and recrystallising from hot alcohol (Siruloboff, *A* 233, 368).

Properties—Monoclinic crystals. Lavoatory. Its aqueous solution is neutral and tasteless, and is not pptd by AgNO₃. Insol alcohol and ether. Decomposed on fusion.

Reactions—1 Boiling water or conc NaOHAq rapidly convert it into C₆H₇O(OH)₂Cl₂.—2 A mixture of HNO₃ and H₂SO₄ gives C₆H₇(ONO₂)₂Cl₂, which crystallises from hot alcohol in needles [145°], insol water.—3 *Sodium amalgam* removes HCl in two stages, forming mannitan chlorhydrin, and finally (β) mannide [119°].

Mannite dibromhydrin C₆H₇(OH)₂Br [178°]. Obtained by heating mannite with conc HBrAq for 2 hours at 100° (Bouchardat, *A Ch* [5] 6, 120). Small colourless plates (from hot water). Decomposed on fusion. Insol cold water, alcohol, and ether. Converted by a mixture of HNO₃ and H₂SO₄ into C₆H₇(ONO₂)₂Br₂, which crystallises in long needles, sol hot alcohol, insol water.

Mannitan C₆H₇O₂, i.e. C₆H₇O(OH)₂. *First anhydride of mannite*. According to Alechin (*J R* 16, 888) the various mannitans described below are mixtures of isomannide and other bodies.

(a) *Berthelot's mannitan* C₆H₇O₂. Obtained in small quantity by heating mannite at 200°. A better method is by protracted boiling of mannite with conc HClAq (Berthelot, *A Ch* [3] 47, 306). Slightly sweetish syrup. Differs from mannite in being soluble in absolute alcohol. V sol water, insol ether. Slightly dextrorotatory (Bouchardat, *A Ch* [5] 6, 102). When exposed to the atmosphere it is partially reconverted into mannite. Boiling alkalis or dilute acids accelerate the change. Above 140° it partly volatilises.

(b) *Vignon's mannitan* C₆H₇O₂ [α]_D = +36.5°. Prepared by heating mannite for an hour or two with half its weight of water at 295°. Also by heating mannite (2 pts) with conc H₂SO₄ (1 pt) at 120°, saturating with BaCO₃, exhausting with alcohol, and evaporating (Vignon, *A Ch* [5] 2, 433). Deliquescent mass, v sol water and absolute alcohol, insol ether. Does not ferment with yeast. Boiling dilute H₂SO₄ or baryta water does not reconvert it into mannite. A mixture of mannitan (1 pt), H₂SO₄ (10 pts), and HNO₃ (4½ pts of SG 1.5) forms in the cold C₆H₇O(OH)(ONO₂), which is obtained on pouring into water and extracting with ether. It is dextrorotatory [α]_D = +53°.

(c) *Vignon's mannitone* C₆H₇O₂ [α]_D = -25°. Obtained by heating mannite with water for 3 hours at 280° and extracting the viscid product with alcohol (Vignon, *A Ch* [5] 2, 433). Crystals (from alcohol). Has a sweet taste. Levorotatory. Does not reduce Fehling's solution. In the preparation of this body the syrupy mother liquor yields a viscid mass, which appears to be the anhydride of mannite or 'mannitic ether' C₆H₇O₂, it does not reduce Fehling's solution, and is levorotatory, [α]_D = -5.6°. This mannitic ether is not converted into mannite or mannitan by boiling dilute acids or alkalis.

(d) *Crystalline mannitan* C₆H₇O₂ S 25 at 15°. When Berthelot's mannitan is allowed to stand for some months in a dry atmosphere it deposits a solid variety (Bouchardat). This crystallises in monoclinic tables. It is strongly levorotatory. Sl sol cold alcohol. Boiling water quickly converts it into mannite. This variety of mannitan is probably identical with Vignon's.

Mannitan tetra nitrate C₆H₇O(ONO₂)₄. Precipitated by adding water to the alcoholic mother liquor from which mannite pentanitrate has separated (Tichanovitch, *J* 1864, 583). Syrup, v sol alcohol and ether, insol water. Explodes when struck. Alcoholic KOH converts it slowly into syrupy mannitan.

Di acetyl derivative C₆H₇O(OH)₂(OAc)₂ [α]_D = +22.6. From mannite and HOAc at 210° (Berthelot). Mannite dissolves in boiling Ac₂O, and on cooling crystals of C₆H₇AcO₂ separate. Further action of Ac₂O yields hexa acetyl mannite and di acetyl mannitan (Schutzenberger, *A* 160, 74, Grange, *C R* 68, 1826). Extremely bitter substance, v sol water, HOAc, and alcohol. Dextrorotatory. Boiling baryta water converts it into acetic acid and mannitan.

Tetra acetyl derivative C₆H₇O(OAc)₄. Formed, together with hexa acetyl mannite, by heating mannite with Ac₂O at 180° (Bouchardat, *A Ch* [5] 6, 110). Amorphous viscid mass, which partially crystallises on long standing.

Insol water, v e. sol alcohol, ether, and HOAc. Dextrorotatory. Aqueous alkalis at 100° decompose it into acetic acid and mannitan. Ac_2O forms hexa-acetyl mannite. A mixture of HNO_3 and H_2SO_4 has no action in the cold.

Di-butyryl derivative

$\text{C}_6\text{H}_5\text{O}(\text{OC}_4\text{H}_7\text{O}_2)_2(\text{OH})_2$. From mannite and butyric acid at 200° (Berthelot, *C R* 38, 673, *A Ch* [3] 47, 319). Semi solid, partly crystalline, mass. Insol water, v sol alcohol and ether.

Tetra butyryl derivative

$\text{C}_6\text{H}_5\text{O}(\text{OC}_4\text{H}_7\text{O}_2)_4$. From mannite and excess of butyric acid at 200°–250°. Oil.

Di-benzoyl derivative

$\text{C}_6\text{H}_5\text{O}(\text{OBz})_2(\text{OH})_2$. From mannite and HOBz at 200° (Berthelot, *Chimie organique*, 2, 193). Soft resin, v e sol alcohol and ether.

Di-ethyl derivative $\text{C}_6\text{H}_5\text{O}(\text{OH})_2(\text{OEt})_2$. From mannite, KOH, and EtBr at 100° (Berthelot). Syrup, v sl sol water, sol alcohol, v e sol ether.

Mannitan chlorhydrin $\text{C}_6\text{H}_5\text{O}(\text{OH})_2\text{Cl}$. From mannite dichlorhydrin by boiling for two hours with 100 pts of water, neutralising with K_2CO_3 , evaporating, and extracting with ether (Bouchardat, *A Ch* [5] 6, 118). Solid mass, v e sol water, alcohol, and ether. Dextrorotatory. Conc HClAq at 100° reconverts it into mannite dichlorhydrin. Boiling water converts it into HCl and mannitan.

Mannitan dichlorhydrin

$\text{C}_6\text{H}_5\text{O}(\text{OH})_2\text{Cl}_2$. From mannite (1 pt) and fuming HClAq (15 pts) by heating for 3 days at 100° (Berthelot, *J* 1856, 661). Crystals, sol ether. KOHAq converts it into mannitan.

Mannitan dibromhydrin $\text{C}_6\text{H}_5\text{O}(\text{OH})_2\text{Br}$. From mannite dibromhydrin by boiling with water. V e sol water, alcohol, and ether. Dextrorotatory.

Mannide $\text{C}_6\text{H}_{11}\text{O}_4$. *Second anhydride of mannite*

(a) *Berthelot's mannide* $\text{C}_6\text{H}_{11}\text{O}_4$ (297°–317°). Obtained by heating mannite with butyric acid at 200°–250° (Berthelot, *A Ch* [3] 47, 312, Liebermann, *B* 17, 874). Thick deliquescent syrup, v e sol cold water and alcohol. Decomposes partially on distillation. In contact with the air it partially forms mannite.

(b) *(β)-Mannide* $\text{C}_6\text{H}_{11}\text{O}_4$ [119°] (212° at 16 mm). S 160 at 15°. S (alcohol) 27 at –16°, 73 at 12°. Obtained by treating mannite dichlorhydrin with sodium amalgam (Siwoloboff, *A* 233, 368). Prisms, v e sol water and alcohol, insol ether. Dextrorotatory. Sublimes at 14°, forming long needles. Does not yield mannite when heated with water. Air and platinum black oxidise it, forming a syrupy liquid.

(c) *Isomannide* $\text{C}_6\text{H}_{11}\text{O}_4$, *+* *e*

$$\begin{array}{c} \text{O} \quad \quad \text{O} \\ \diagdown \quad \diagup \quad \diagdown \quad \diagup \\ \text{CH}_2(\text{OH}) \text{CH} \text{CH} \text{CH} \text{CH}_2 \text{OH} \end{array}$$

[87°] (176° at 30 mm) (274° at 760 mm) $[\alpha]_D^{20} = +91.4$ in a 6 p c aqueous solution. Obtained by distilling mannite *in vacuo*, the product being fractionally distilled *in vacuo* (Fauconnier, *C R* 95, 991). Prepared by boiling mannite (200 g) with HClAq (2,000 g) for 24 hours, cooling, filtering, and distilling *in vacuo*. The distillate is allowed to stand for a fortnight, extracted with cold alcohol, the extract distilled *in vacuo*, and the frac-

tion boiling at 176° recrystallised from alcohol (Fauconnier, *Bl* [2] 41, 119). Large monoclinic, somewhat deliquescent, crystals. Boils at 274° with partial decomposition. V e sol water, m sol alcohol, sl sol chloroform, insol ether and benzene. Dextrorotatory. Not affected by heating with water at 150°. By heating with fuming HClAq in sealed tubes at 100° for 25 days it is converted into mannite dichlorhydrin $\text{C}_6\text{H}_5(\text{OH})_2\text{Cl}_2$ [174°]. It is not acted upon by POCl_3 , by bromine in the cold, or by sodium-amalgam.

Di-formyl derivative $\text{C}_6\text{H}_5\text{O}_2(\text{OCHO})_2$ [115°] (166° at 18 mm). Small plates, sl. sol cold water, v sol alcohol, sol ether.

Acetyl derivative $\text{C}_6\text{H}_5\text{O}_2(\text{OH})(\text{OAc})$ (186° at 25 mm.). From isomannide and Ac_2O . Colourless oil, sol ether.

Di-benzoyl derivative $\text{C}_6\text{H}_5\text{O}_2(\text{OAc})_2$ (198° at 28 mm). From isomannide (1 pt) by boiling with Ac_2O (3 pts) for 8 hours. Viscid liquid, with bitter taste. Not altered by further treatment with Ac_2O .

Di-benzoyl derivative $\text{C}_6\text{H}_5\text{O}_2(\text{OBz})_2$ [132°]. From mannite, alcohol, ZnCl_2 , HCl, and BzCl (Meunier, *C R* 107, 346). Monoclinic or triclinic crystals, v sl sol water and cold alcohol, sol chloroform and benzene. Not decomposed by aqueous acids or alkalis.

Methyl derivative $\text{C}_6\text{H}_5\text{O}_2(\text{OH})(\text{OMe})$ [48°] (174° at 24 mm). From isomannide, KOH, MeI, and a little water at 150°. Crystals.

Ethyl derivative $\text{C}_6\text{H}_5\text{O}_2(\text{OH})(\text{OEt})$ (165° at 17 mm). Formed by heating mannite, EtI, and conc KOHAq in sealed tubes for 4 hours at 120°. Colourless mobile liquid, sol water, alcohol, and ether.

Isomannide dichlorhydrin $\text{C}_6\text{H}_5\text{O}_2\text{Cl}_2$ [49°] (143° at 43 mm). From isomannide (1 pt) by warming with PCl_5 (2 pts). White needles or plates, v sol ether, m sol alcohol. Insol cold, sol hot, water. Has a strong aromatic odour and a peppery taste. May be distilled with steam. It is very stable, not being attacked by alcoholic KOH at 150°, by PCl_5 at 125°, or by sodium amalgam.

Anhydride of mannide $\text{C}_2\text{H}_5\text{O}_4$, *+* *e* ($\text{C}_2\text{H}_5\text{O}_2(\text{OH})_2\text{O}$) (?) Deposited on standing from a sample of butyric acid (Geuther, *A* 221, 59). Gummy.

Lævo mannite $\text{C}_6\text{H}_{11}\text{O}_4$ [164°]. Formed by reducing lævo mannose with sodium amalgam. Globular groups of fine needles, v sol water, sl sol absolute alcohol, much more sol methyl alcohol. It tastes sweet, and does not reduce Fehling's solution. A solution of this mannite containing borax turns the ray of polarised light to the left. This substance is probably the one obtained by Kiliani (*B* 20, 2714) by reduction of the double lactone of metasaccharic acid (Emil Fischer, *B* 23, 375).

Inactive mannite *a Acrite* [168°]. Formed by reducing inactive mannose with sodium-amalgam. Small prisms (from water), v sol water, m sol hot glacial acetic acid, sl sol methyl and ethyl alcohols. It is easily distinguished from ordinary mannite by its crystalline form and by its optical inactivity. A solution containing borax remains wholly inactive. This mannite is identical with (*a*) acrite, a substance obtained by the action of sodium amalgam on

(e)-acrose, a sugar obtained by the action of alkalis on acrolein dibromide (Fischer, *B* 22, 100) By oxidation with dilute HNO_3 inactive mannose is formed (Emil Fischer, *B* 23, 383)

The mannites may be distinguished optically by means of their phenyl hydrazides 1 g of the phenyl hydrazide dissolved in 1 c c of cold conc HClAq and 5 c c of water gives in a tube 100 mm long a rotation of $+1.2^\circ$, -1.2° , and 0° , with the levo-, dextro, and inactive mannite respectively In the course of 3 or 4 hours the rotation vanishes, the phenyl hydrazide being decomposed by the HCl When the di phenyl dihydrazide is used 1 g is dissolved in warm HOAc , cooled, and examined in a 100 mm tube It gives a rotation of $+0.85^\circ$, -0.85° , or 0° in the case of the levo-, dextro-, and inactive compounds respectively The dextro and levo mannites themselves scarcely exhibit a rotation, but 15 g of the mannite dissolved in 5 c c water containing 37 g borax exhibits a rotation of $+0.85^\circ$, -0.85° , or 0° , according as the mannite is dextro-, levo-, or inactive (Fischer)

MANNITIC ACID $\text{C}_6\text{H}_{12}\text{O}_7$ Prepared by mixing mannite (2 g) with platinum black (4 g), moistened with water, and exposing the mixture at 30° to 40° to the air for 3 weeks The mass is then exhausted with water, the solution ppd. by lead subacetate, the pp decomposed by H_2S , and the solution evaporated in the cold over H_2SO_4 (Gorup Besanez, *A* 118, 257) Gummy mass, sol water and alcohol, nearly insol ether It is a strong acid, and dissolves zinc with evolution of hydrogen It begins to decompose at 80° It reduces silver nitrate solution and hot Fehling's solution It is ppd by baryta and by lime water— CaA'' amorphous powder, ppd by adding alcohol to its aqueous solution CuA'' green amorphous mass left by evaporating its solution— PbA'' granular— AgA'' curdy pp

MANNITINE $\text{C}_6\text{H}_{12}\text{N}_2$ (170°) Prepared by distilling a mixture of mannite (1 mol) and ammonium chloride (2 mols) The distillate is mixed with KOHAc and shaken with ether (Seichlone a Denaro, *G* 12, 416, Etard, *C R* 92, 795) Brown oil, with strong odour, sol alcohol and ether, m sol water Gives an orange yellow pp with sodium phosphomolybdate, a reddish yellow pp with iodine in $\text{KI} \text{Aq}$, a pink pp with HgCl_2 , and a black pp with auric chloride Hypodermically injected it produces diminution of the cardiac systole, and irregular respiration, followed by insensibility and death

MANNITOSE $\text{C}_6\text{H}_{12}\text{O}_6$ Produced, together with mannitic acid, by the atmospheric oxidation of mannite in the presence of platinum black (Gorup Besanez, *A* 118, 273) Optically inactive Fermentable Reacts like glucose with alkalis, Fehling's solution, basic bismuth nitrate, and Na_2CO_3 , but it does not unite with NaCl Its alcoholic solution gives with alcoholic potash a pp of $(\text{C}_6\text{H}_{11}\text{O}_6)_2\text{K}_2\text{O}$ Mannitose is perhaps identical with levulose (Dafert, *B* 17, 228, 19, 911)

MANNONIC ACIDS $\text{C}_6\text{H}_{10}\text{O}_7$

Inactive mannonic acid *Lactone* $\text{C}_6\text{H}_{10}\text{O}_6$ [155°] Formed from inactive mannose by oxidation with bromine (E Fischer, *B* 23, 876) Long glittering prisms, grouped in stars of

needles (from alcohol), v sol hot water, sl sol hot alcohol Has a sweet taste and does not reduce Fehling's solution By means of the strychnine salt it can be split up into dextro-mannonic acid and arabinose carboxylic acid, the strychnine salt of the latter being extremely sl sol alcohol The morphine salts may also be employed, morphine dextro mannonate crystallising out *Penicillium glaucum* partly decomposes inactive mannonic acid, liberating some arabinose carboxylic acid— $\text{Ca}(\text{C}_6\text{H}_9\text{O}_6)_2$ Groups of slender needles Less soluble than calcium levo mannonate

Phenyl hydrazide $\text{C}_{12}\text{H}_{18}\text{N}_2\text{O}_6$ [230°] Colourless cubes, sl sol hot water, v sl sol alcohol Split up by hot baryta water into phenyl hydrazine and inactive mannonic acid

Dextro-mannonic acid Formed from gluconic acid by heating with twice its weight of quinoline for 40 minutes to 140° (Emil Fischer, *B* 23, 801) Formed also as above and by oxidation of dextro mannose by bromine By heating dextro mannonic acid with quinoline, gluconic acid is formed For this purpose 20 g of dextro mannonic acid, 5 g water, and 40 g quinoline are heated to 140° for 40 minutes The unchanged mannonic acid is separated by means of its brucine salt Dextro mannonic acid, like the other mannonic acids, when liberated from its salts condenses at once to the lactone $\text{C}_6\text{H}_{10}\text{O}_6$ [149°–153°] Its rotation, $[\alpha]_D = 53.8$, is equal and opposite to that of the lactone of arabinose-carboxylic acid, which is therefore levo mannonic acid

Salts— $\text{Ca}(\text{C}_6\text{H}_9\text{O}_6)_2$ 2aq— SrA' , 3aq— BaA' , (dried at 100°)

Phenyl hydrazide $\text{C}_{12}\text{H}_{18}\text{N}_2\text{O}_6$ [216°] Small colourless prisms, v sol, hot water Decomposed by hot baryta water into dextro mannonic acid and phenyl hydrazine

Levo-mannonic acid Lactone $\text{C}_6\text{H}_{10}\text{O}_6$ *Arabinose carboxylic acid* [145°–150°] $[\alpha]_D = -54.8$ Formed from arabinose (v ARABIC ACID and SUGARS) by treatment with HCy and saponification of the product (Kiliani, *B* 19, 3033) Formed also from inactive mannonic acid, as above

MANNOSE $\text{C}_6\text{H}_{12}\text{O}_6$ 16
 $\text{CHO CH(OH) CH(OH) CH(OH) CH(OH) CH}_2\text{(OH)}$
Dextro mannose $[\alpha]_D = +13^\circ$ Formed by heating 3 kilos of mannite with 20 litres of water and 10 litres of HNO_3 (S G 141) in the water bath with shaking to 40° – 45° until a test portion rendered neutral with soda gives a thick pale-yellow pp of the hydrazide with phenyl-hydrazine acetate The whole is then cooled with ice to about 25° , made feebly alkaline with crystallised Na_2CO_3 , acidified with acetic acid, and treated with 1 kilo of phenylhydrazine dissolved in dilute acetic acid The phenylhydrazide crystallised from hot water is converted into the sugar by solution in HCl (S G 119), allowing to stand, cooling, filtering, and neutralising the diluted filtrate with pure carbonate of lead The whole is again filtered, made alkaline with Ba(OH)_2 , and shaken with ether The aqueous solution separated from ether contains the sugar, which remains as a syrup on evaporating, and is ppd from absolute alcohol by ether (Emil Fischer a Josef Hirschberger, *B* 21, 1806, 22, 365), Mannose may

more easily be got from vegetable ivory nuts, *v* *Seminosae infra*

Properties—Light yellow syrup, with sweet taste. *V* sol water and alcohol. Reduces Fehling's solution, 1 cc corresponding to 0.04307 g of mannose. Turned brown by heating with 20 p.c. HClAq, the solution then containing levulic acid. Ferments easily with yeast, giving CO_2 and alcohol. The aqueous solution is dextrorotatory, but less so than glucose. Sodium-amalgam (2 p.c.) reduces mannose to mannite. Furfuraldehyde is formed by heating a dilute solution of mannose at 110° for four hours. AsCl forms a substance like acetochlorhydrone.

Phenyl hydrazide $\text{C}_{12}\text{H}_{15}\text{N}_3\text{O}_5$ [195° – 200°] *S* 1 at 100° . Prepared as above. Slender prisms (from water). *Sl* sol alcohol and acetone. Its solution in dilute HClAq is levorotatory. Concentrated mineral acids convert it into mannite and phenyl hydrazine even in the cold. When it is heated with phenyl hydrazine hydrochloride (3 pts), NaOAc (4 pts) and water (80 pts) at 105° for 4 hours there is formed the 'osazone' of glucose $\text{C}_{18}\text{H}_{22}\text{N}_4\text{O}_8$, which crystallises from alcohol in slender yellow needles [206°].

Oxime $\text{C}_6\text{H}_{11}\text{O}_2\text{N}$. Crystalline, *v* sol hot water, *insol* alcohol. When slowly heated it melts at 176° – 180° , but when quickly heated, at 184° (Fischer a Hirschberger, *B* 22, 1155).

Inactive mannose. Formed by reducing the lactone of inactive mannonic acid with sodium-amalgam (E Fischer, *B* 23, 381). Colourless syrup, *v* sol water, *sl* sol absolute alcohol, *m* sol hot methyl alcohol. Resembles (dextro) mannose except in being inactive. When subjected to fermentation levomannose is left. Bromine oxidises it to inactive mannonic acid.

Phenyl hydrazide [195°]. Decomposed on fusion. *Sl* sol water. Its solution in HCl is optically inactive. Cold conc HCl splits it up into sugar and phenyl hydrazine.

Di-phenyl hydrazide $\text{C}_{18}\text{H}_{22}\text{N}_4\text{O}_8$ [218°]. Formed by heating the inactive mannose with phenyl hydrazine (2 mols), the corresponding quantity of acetic acid and water. Fine yellow glittering needles, *sl* sol water, cold alcohol, and ether. Decomposes on fusion. At 45° conc HCl forms the corresponding osone. The solution in 60 pts glacial acetic acid is optically inactive. The properties of this di-phenyl-hydrazide are the same as those of (a) acrosazone (the di-phenyl hydrazide of (a) acrose), and Emil Fischer (*B* 23, 383) considers that they are identical.

Levo-mannose. To prepare this body 1 pt of the lactone of arabinose carboxylic acid is dissolved in 10 pts water, acidified with H_2SO_4 , and cooled to 0° . $2\frac{1}{2}$ p.c. sodium amalgam is added in small portions. The liquid must remain acid. Colourless syrup, *v* sol water, *sl* sol absolute alcohol, *m* sol methyl alcohol. The aqueous solution is slightly levorotatory. It ferments little, if at all, with yeast.

Phenyl hydrazide $\text{C}_{12}\text{H}_{15}\text{N}_3\text{O}_5$ [195°]. Formed by adding phenyl-hydrazine acetate to a solution of the sugar. Slender, almost colourless crystals. It is more sol water than the dextro mannose phenyl hydrazide. The hydrochloric acid solution is dextrorotatory. Cold HCl splits up the compound into phenyl-hydrazine and mannose.

Di-phenyl hydrazide [205°]. Formed by heating the levo mannose phenyl hydrazide with phenyl hydrazine acetate and 30 pts water to 100° . Fine yellow needles (from water). Decomposed on fusion. It is extremely like the di-phenyl hydrazide of dextro mannose, levulose, and dextrose. It, however, turns the ray of polarised light strongly to the right (Emil Fischer, *B* 23, 373).

Isomannitose, a sugar obtained, together with glucose, by boiling salep with acids, is probably identical with mannose (Tollens, *B* 21, 2150). Its phenyl hydrazide $\text{C}_{12}\text{H}_{15}\text{N}_3\text{O}_5$ [188°] is *sl* sol alcohol.

Seminosae, obtained by digesting with dilute H_2SO_4 , the cellulose composing the thick walled cells of the endosperm of vegetable ivory nuts, is identical with mannose (Reiss, *B* 22, 609, Schultz, *B* 22, 1192, Fischer a Hirschberger, *B* 22, 3218).

'Mannose carboxylic acid' $\text{C}_6\text{H}_{11}\text{O}_5$ *etc.* $\text{C}_6\text{H}_{11}(\text{CO}_2\text{H})\text{O}_2$. From mannose (50 g) by dissolving in water (250 g) and adding anhydrous HCl (18 cc) and a few drops of ammonia. After three days the mixture is heated to 50° for 4 hours. The product appears to contain the ammonium salt of the acid and its amorphous a nide [183°], which may be pptd by alcohol (Fischer a Hirschberger, *B* 22, 365). The acid changes to anhydride when set free from its salts. In preparing the lactone (*v infra*) an acid [c 169°], probably the free mannose carboxylic acid, is sometimes formed.

Salts—*BaA'*. Obtained by boiling the ammonium salt with baryta. Colourless, semi-crystalline mass, *m* sol hot, *v* *sl* sol cold, water, *insol* alcohol. Boiling conc HIAq reduces it slowly to *n* heptonic acid.

Lactone $\text{C}_6\text{H}_{10}\text{O}_5$ [150°]. Obtained by decomposing a hot solution of the *Ba* salt with the theoretical quantity of H_2SO_4 . Needles, *v* sol water, *m* sol alcohol, *insol* ether.

Phenyl hydrazide $\text{C}_{18}\text{H}_{22}\text{N}_4\text{O}_8$, *Ph* [220° – 223°]. Formed by boiling the *Ba* salt with aqueous NaOH , and adding HOAc and phenyl hydrazine acetate (Fischer a Passmore, *B* 23, 2732). Very small prisms, *sol* hot water. Decomposed on fusion.

MANTLE MUCIN *v* PROTEIDS, *Appendix C*.

MARGARIC ACID $\text{C}_{17}\text{H}_{33}\text{O}_2$ (*Heptadecanoic acid*) *Mol* *v* 270 [60°]. The name margaric acid was originally applied to an acid $\text{C}_{17}\text{H}_{33}\text{O}_2$ supposed to occur in the product of the saponification of solid natural fats, but this acid was shown by Heintz to be a mixture of palmitic acid $\text{C}_{16}\text{H}_{32}\text{O}_2$ and stearic acid $\text{C}_{18}\text{H}_{36}\text{O}_2$. An acid $\text{C}_{17}\text{H}_{33}\text{O}_2$ occurs, however, according to Ebert (*B* 8, 775), in adipocere, a substance formed in dead tissues of animals. Formed by boiling its nitrile (cetyl cyanide) with alcoholic potash (Heintz, *P* 102, 272). White crystals—*BaA'*, white amorphous powder—*AgA'* white amorphous powder.

Nitrile $\text{C}_{16}\text{H}_{31}\text{CN}$ [53°] (?) (Köhler, *J* 1856, 579, cf Becker, *A* 102, 213). According to Heintz (*J* 1857, 445), margaritrile prepared from potassium cetyl sulphate and KCN is an oil.

Margaric acid $\text{C}_{17}\text{H}_{33}\text{O}_2$ [60° uncor.]. (277° at 100 mm). Prepared by the oxidation

of methyl-heptadecyl-ketone (Krafft, *B* 12, 1672) Probably identical with the preceding acid

MARJORAM OIL $\text{SG} \approx 911$ (Bruylants)

The essential oil obtained by steam distillation from the flowers of sweet marjoram (*Majorana hortensis* or *Origanum majorana*) Yellow oil which becomes brown on standing It has a pungent smell, a hot peppery taste, and an acid reaction According to Bruylants (*J Ph* [4] 30, 33, cf Mulder, *A* 31, 69) it begins to boil at 185° and the thermometer remains stationary at 215° – 220° Bruylants found it to consist of 5 p.c. of dextrorotatory terpene, 85 p.c. of a mixture of dextrorotatory camphor and borneol, and 10 p.c. of resin According to Kane (*A* 32, 285) the essential oil of wild marjoram (*Origanum vulgare*) contains a terpene which boils at 161° and has SG 867 According to Beilstein a Wiegand (*B* 15, 2855) oil of sweet marjoram contains a terpene $\text{C}_{10}\text{H}_{18}$ (178° 1 V) $\text{SG}^{18.5}$ 846, which absorbs HCl , forming liquid $\text{C}_{10}\text{H}_{17}\text{HCl}$ By distilling the oil of marjoram over sodium Beilstein a Wiegand obtained liquid $\text{C}_{10}\text{H}_{18}\text{O}$ (200° – 220°)

Cretan oil of marjoram from *Origanum hirtum* has $\text{SG} \approx 951$, and 100 mm produce a rotation of -0.4° It contains 50 p.c. of carvacrol [2 $^\circ$] and dissolves in half its volume of 15 p.c. soda solution (Jahns, *Ar Ph* [3] 15, 1, 16, 277) The oil also contains a mixture of terpenes, and a phenol that is coloured violet by FeCl_3 , Jahns found a little carvacrol in the oil from *Origanum vulgare*

MARRUBIUM [160°] The bitter principle of white horehound (*Marrubium vulgare*) (Kro Mayer, *Ar Ph* [2] 108, 257, Harms, *J* 1863, 593) Prepared by exhausting the dried herb with hot water, evaporating, and extracting with alcohol Large tables (from ether) or needles (from alcohol) Almost insol cold, sl sol hot, water Not affected by alkalis Metallic salts do not ppt it Not pptd by tannin Hot conc HClAq does not affect it Conc H_2SO_4 gives a brownish yellow solution Cold HNO_3 has no action, hot HNO_3 forms a yellow solution

MARSH GAS v METHANE

MARTYLAMINE v p AMIDO DIPHENYL

MASOPIN $\text{C}_{22}\text{H}_{40}\text{O}$ [155°] Occurs in a resin used in Mexico for chewing, said to be the dried juice of a tree called Dschlite The resin occurs in porous lumps, smelling like rotten cheese, but with little taste The masopin is obtained by boiling the resin with water, and crystallising the residue from alcohol (Genth, *A* 46, 124) White silky needles (from ether) After fusion, it melts a second time at 70° On distillation it yields a terpene and a crystalline acid, of which the Ag salt contains 45.5 p.c. of silver

MASTIC A resin obtained by incisions in the bark of *Psittacia lentiscus*, a tree growing in Chios Small round transparent grains with faint agreeable odour Used for making varnishes and, from the earliest times, for chewing Softens when masticated SG 1.074 Aqueous alcohol dissolves the greater part $\text{C}_{15}\text{H}_{26}\text{O}_2$, leaving masticin $\text{C}_{16}\text{H}_{28}\text{O}_2$ undissolved (Johnston, *P T* 1839, 182) Flückiger (*Ar Ph* 219, 170) found 2 p.c. of a dextrorotatory terpene in mastic.

MATEZITE $\text{C}_{15}\text{H}_{26}\text{O}$, [187°] $[\alpha]_D = -64.7$

Occurs in Madagascar caoutchouc (mateza rorina) (Girard, *Bl* [3] 21, 220, *C R* 110, 84) Identical with (8) Pinite (Combes, *C R* 110, 46). Crystalline nodules, v sol water, m sol alcohol Sublimes above 200° Resembles dambonite but is dextrorotatory Fuming HIAq splits it upon heating into Mel and matezo dambose $\text{C}_{15}\text{H}_{26}\text{O}_2$ [246°] $[\alpha]_D = 67.6$, which is dextrorotatory and more soluble in water than dambose Matezo dambose is identical with the (8) inosite of Maquenne (*C R* 109, 812) It forms small tetrahedra when pptd by adding alcohol to its aqueous solution

MATICIN A bitter substance which remains dissolved in the water in the retort in the preparation of the essential oil of matico by distilling the leaves of *Piper aspersifolium* with steam It is sol water and alcohol, and insol ether (Hodges, *P M* [3] 25, 204, *C S Mem* 1, 123) Its solution is not pptd by lead acetate

MATICO-CAMPHOR $\text{C}_{15}\text{H}_{26}\text{O}$ [94°] Occurs in the essential oil of matico leaves (*Piper angustifolium*), from which it is obtained by distilling off the greater part and allowing the residue to crystallise (Kugler, *B* 16, 2841) Hexagonal crystals V sol alcohol, ether, benzene, petroleum ether, &c With HCl it gives a violet colour, passing into blue, and finally becoming green. H_2SO_4 colours it yellow, then red, and lastly violet A mixture of H_2SO_4 and HNO_3 first produces a yellow, which then becomes violet, and finally a splendid blue

MAUVANILINE $\text{C}_{15}\text{H}_{11}\text{N}_3$ A by product in the preparation of rosaniline by the oxidation of crude aniline (De Laire, Girard a Chapoteaut, *C R* 64, 410, *Bl* [2] 7, 366), cf Girard a Pabst, *Bl* [2] 34, 37) Light brown crystals (containing $\frac{1}{2}$ aq, which is given off at 130° with decomposition) Insol cold, v sl sol hot, water, sol alcohol, ether, and benzene Its salts form lustrous bronze green crystals, v sl sol cold water, and dye silk and wool mallow red Tri ethyl-mauvaniline $\text{C}_{15}\text{H}_{11}\text{Et}_3\text{N}_3$ dyes bluish violet, while tri phenyl mauvaniline $\text{C}_{15}\text{H}_{11}\text{Ph}_3\text{N}_3$ is a blue dye

MAUVEINE $\text{C}_{15}\text{H}_{11}\text{N}_3$ The first aniline dye introduced (Perkin, 1856) Obtained by adding a cold dilute solution of a salt of crude aniline to a cold dilute solution of $\text{K}_2\text{Cr}_2\text{O}_7$, and leaving the mixture to stand for 12 hours The resulting black pp is dried, extracted with benzene, dissolved in alcohol, and the filtrate evaporated When aniline sulphate is used the product is $(\text{C}_{15}\text{H}_{11}\text{N}_3)_2\text{SO}_4$, aniline hydrochloride yields $\text{C}_{15}\text{H}_{11}\text{N}_3\text{Cl}$ (Perkin, *A* 131, 200, *C J* 35, 717) On adding aqueous KOH to a solution of a salt of mauveine the base separates as a violet black crystalline substance It dissolves in alcohol, forming a violet solution, which on addition of acids turns purple Mauveine is insol benzene and ether With dilute acids it forms purple solutions, with stronger acids, blue Conc H_2SO_4 forms a dirty green solution Dyes silk mauve Used for postage stamps Oxidised by PbO_2 and boiling HOAc it gives para safranine $\text{C}_{15}\text{H}_{13}\text{N}_3$

Salts — B/HCl tufts of small prisms with green metallic lustre Insol cold, sl sol hot, water, m sol alcohol, nearly insol ether — B/HCl blue, with copper lustre Unstable. Becomes B/HCl when dissolved in alcohol —

B⁺ H₂PtCl₆, green crystalline powder, v sl sol alcohol —B⁺ H₂PtCl₆, blue —B⁺ H₂SO₄, —B⁺ HBr —B⁺ Hl lustrous prisms —B⁺ H₂SO₄, —B⁺ H₂CO₃, prisms, with green metallic lustre On boiling its solution CO₂ is given off

Ethyl mauveine C₂₂H₂₀EtN₂, Formed by heating mauveine with EtI at 100° Its colour is redder than that of mauveine During the manufacture crystals of C₂₂H₂₀EtN₂HI, sometimes appear —C₂₂H₂₀EtN₂HI Forms a reddish purple solution in alcohol —(C₂₂H₂₀EtN₂HI).PtCl₆, Golden green lustre

Pseudo-mauveine C₂₂H₂₀N₂ (Perkin, G. J. 85, 725) Present in commercial mauveine It is more soluble in alcohol than mauveine It is a strong base, and dyes silk almost exactly like mauveine Pure aniline gives pseudo mauveine on oxidation, hence it does not contain methyl Mauveine is probably derived from aniline and *p* toluidine The violet colouration given by bleaching powder to a dilute solution of aniline is probably due to pseudo-mauveine —C₂₂H₂₀N₂HI Greenish-golden lustre —(B⁺ HCl).PtCl₆

MAYER'S REAGENT v ALKALOIDS, Reaction 3

MAYNAS RESIN *Calaba* or *Galba* of the Antilles (Lewy, A. Ch. [3] 10, 380) A resin extracted by incision from *Calophyllum calaba* Alcohol extracts from it C₂₁H₃₄O₄, which separates on cooling in yellow monoclinic prisms Maynas resin is insol water, but v sol KOHAq and ammonia It melts about 105°

MECCA BALSAM *Balm of Gilead* The produce of *Balsamodendron gileadense*, a shrub growing in Arabia Felix There appear to be several varieties of it It contains a fragrant volatile oil, an acid resinol alcohol, and a resin, insoluble in alcohol (Bonastre, A. 3, 147, cf Trommsdorff (Trommsd. Neues Journal, 16, 62)

MECONIC ACID C₁₅H₈O₆, 3aq, *tc* C₁₅H₈O₆(OH)(CO₂H)₂, Mol w 200 S 25 at 100° Heat of neutralisation (4 mols NaOH) 87,382 (Gal a Werner, B1 [2] 47, 162) Electrical conductivity Ostwald (J. pr. [2] 32, 368)

Occurrence —In opium (Serturmer, Am. S. 55, 72, 57, 183, 64, 65, Robiquet, A. Ch. 5, 232, 51, 236, 53, 425, Liebig, A. 7, 87, 26, 118, 147)

Preparation —Opium is exhausted with water at 38°, the extract is neutralised with CaCO₃, evaporated to a syrup, and mixed with a concentrated solution of CaCl₂, which ppts calcium meconate The pp (1 pt) is suspended in conc HClAq (3 pts) mixed with boiling water (20 pts), and kept near 100° till dissolved On cooling, acid calcium meconate separates in crystals These (1 pt) are again dissolved in a mixture of HClAq (3 pts) and boiling water (20 pts), and, on cooling, meconic acid separates (Gregory, A. 24, 43) It may be further purified by crystallising its ammonium salt from water (How, A. 83, 350)

Properties —Micaceous scales or small trimetric prisms (containing 3aq) (Burghardt, C. J. 27, 937) It gives off its water of crystallisation at 100°, then becoming a white opaque mass Has a sour taste and strongly reddens litmus Sl sol cold water, v sl alcohol, sl sol ether FeCl₃ colours its solutions blood red This colouration, like that with sulphocyanides, is

much weakened by oxalic acid and by metaphosphoric acid (Dupré, C. N. 32, 15), but it is not destroyed by boiling or by dilute HClAq Meconic acid may be regarded as a derivative of the hypothetical $\text{CH} \begin{smallmatrix} \text{CH} & \text{CH} \\ \diagdown & \diagup \\ \text{CH} & \text{CH} \end{smallmatrix} > \text{O}$

Reactions —1. Heated at 180° it gives off CO₂, and comenic acid C₈H₆O₄(OH)(CO₂H) remains At a higher temperature the comenic acid is further resolved, partly into CO₂ and pyromeconic acid C₈H₆O₄(OH), and partly into water, acetic acid, and oily and carbonaceous products 2 When boiled with water or with HClAq it gives CO₂ and comenic acid —3 Nitric acid oxidises it, forming oxalic acid —4 Boiling conc KOHAq also yields oxalic acid —5 Boiling aqueous ammonia forms comenamic acid C₈H₆NO(OH)CO₂H Comenamic acid yields pyridine on dry distillation with zinc-dust (Lieben a Hattinger, B. 16, 1263) The comenamic acid is di oxy picolinic acid, and comenic acid is probably an intermediate product in its formation —6 Bromine, acting on its aqueous solution, forms a brominated comenic acid —7 Aqueous HI gives comenic acid —8 Sodium amalgam reduces it to hydro meconic acid —9 Gives with alcohol and HCl a di ethyl ether, C₈H₆O₄(OH)(CO₂Et)₂, whence a silver compound, C₈H₆O₄(OAg)(CO₂Et)₂, which gives with EtI a tri ethyl derivative C₈H₆O₄(OEt)₃(CO₂Et)₂ [61°] This gives no colour with FeCl₃ (Öst a Mennel, J. pr. [2] 23, 439) —10 PCl₅ converts it into a liquid chloride, probably C₈H₆Cl₂(COCl)₂, whence ice water forms 'chloro meconic' acid, C₈H₆ClO(OH)(CO₂H)₂, aq [165°], whereas warm water forms only oxalic acid (Hilsebein, J. pr. [2] 32, 136) Chloro meconic acid gives a green colour, with solution of ferric chloride It forms an ether, C₈H₆ClO(OH)(CO₂H)(CO₂Et)₂, [148°], which gives an acetyl derivative C₈H₆ClO(OAc)(CO₂H)(CO₂Et)₂, [70°] It also forms barium salts Chloro meconic acid is decomposed by sublimation into carbonic acid and yellowish needles of *pyro chloro meconic acid*, C₈H₆ClO(OH)₂, aq [174°] The solution of this acid is turned dark green by FeCl₃ Its alcoholic solution turns the skin red It forms a crystalline calcium salt, (C₈H₆ClO₂)₂Ca Chloro meconic acid dissolves in conc NH₃, the solution turning successively red, violet, and blue, owing to the formation of two nitrogenous colouring matters, 'meconic blue' and 'meconic red' Chloro meconic acid is reduced by treatment with sodium amalgam, forming *di-hydro chloro meconic acid* C₈H₆ClO(OH)(CO₂H)₂, [145°] Fuming HI at 100° reduces chloro meconic acid to an *oxy pentane di carboxylic acid*, C₈H₁₀O(CO₂H)₂ This body forms groups of needles [149°] Its silver salt, Ag₂A'', is a crystalline powder, insol water Its barium salt, BaA'', forms white prisms Its ether, Et₂A'', is an oil, boiling about (250°) Oxy-pentane di carboxylic acid, when distilled with lime, yields amyl alcohol, (c 130°) (Hilsebein J. pr. [2] 32, 129–153)

Salts —(NH₄)₂HA''' aq granular crystals, sl sol water —(NH₄)₂HA''' aq slender needles —A barium salt is ptd by adding BaCl₂ to a solution of an alkaline meconate, in white flakes, soluble in acetic acid —CaHA'''₂ aq ptd by adding CaCl₂ to aqueous meconic acid —CaHA''' aq yellow gelatinous pp, formed by

adding CaCl_2 to a solution of ammonium meconate.—The cupric salts are green pps.— $\text{Pb}_2\text{A}''$, 2aq white flocks, ppd by adding lead acetate to a solution of meconic acid (Stenhouse, *A* 51, 281).—A sparingly soluble ferric salt may be obtained by the action of ferric sulphate on ammonium meconate (Stenhouse)— $\text{Fe}_2\text{Ca}_2\text{A}'''$, 6aq (Rennie, *C N* 42, 75)— $\text{Ag}_2\text{HA}''$ white pp got by adding AgNO_3 to a solution of meconic acid— $\text{Ag}_2\text{A}''$ yellow pp from ammonium meconate and AgNO_3 .—Aniline salt $(\text{C}_6\text{H}_5\text{NH}_2)_2\text{C}_2\text{H}_3\text{O}_2$, crystalline (Korff, *A* 138, 195)—Urea salt $(\text{CON}_2\text{H}_4)_2\text{C}_2\text{H}_3\text{O}_2$, (Hlasiwetz, *J* 1856, 699)—Narceine salt [126°] from narceine (1 mol) and meconic acid (1 mol) Lemon yellow crystals, sol hot water (Merck, *C G* 1889, 384).—The acid morphine salt could not be obtained by Dott (*Ph* [3] 17, 690) It will be observed that meconic acid has but little tendency to form tribasic salts, so that it might perhaps be more correctly regarded as a dibasic acid (cf Dittmar & Dewar, *Pr E* 1867, Dott, *Ph* [3] 11, 576)

Ethyl derivative $\text{C}_2\text{H}_3\text{O}_2(\text{CO}_2\text{H})_2(\text{OEt})$ [200°] Formed by boiling $\text{C}_2\text{H}_3\text{O}_2(\text{CO}_2\text{Et})_2(\text{OEt})$ for forty eight hours with water, and evaporating the solution Small prisms grouped in lumps Decomposed by fusion Gives no colour with FeCl_3 Gives, with most metallic salts, no pp Lead acetate is an exception Heated alone till it melts, CO_2 is given off, and the ethyl derivative of meconic acid formed Its aqueous solution is converted by bromine into a brominated derivative of meconic ether— PbA'' 1½aq Crystalline pp

Mono ethyl ether

$\text{C}_2\text{H}_3\text{O}_2(\text{CO}_2\text{Et})(\text{CO}_2\text{H})(\text{OH})$ [179°] Prepared by dissolving meconic acid in alcohol, heating to 100°, and subjecting to a current of HCl till crystals begin to appear The liquid on cooling deposits crystals of the mono ethylic ether (E Mennel, *J pr* [2] 26, 450) It gives a red colour with FeCl_3 .—Silver salt $\text{C}_2\text{H}_3\text{O}_2(\text{CO}_2\text{Et})(\text{CO}_2\text{Ag})(\text{OH})$, aq—Barium salts $\text{BaC}_2\text{H}_3\text{O}_2$, and $\text{Ba}(\text{C}_2\text{H}_3\text{O}_2)_2$.

Di ethyl ether $\text{C}_2\text{H}_3\text{O}_2(\text{CO}_2\text{Et})_2(\text{OH})$ [112°] Prepared by passing HCl into an alcoholic solution at 100° until the crystals (of mono ethylic ether) which are first formed are dissolved up again On pouring into water, plates of the di ethylic ether separate (How, *A* 83, 350, Mennel, *J pr* [2] 26, 453) Plates From dilute solutions it crystallises with ½aq as needles Gives a red colour with FeCl_3 An amorphous pp is formed by adding AgNO_3 and then exactly neutralising with NH_3 .— $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$, needles (from alcohol), v sol water Its solution is ppd by various metallic salts

Ethyl derivative of the diethyl ether $\text{C}_2\text{H}_3\text{O}_2(\text{CO}_2\text{Et})_2(\text{OEt})$ [61°] From $\text{C}_2\text{H}_3\text{O}_2(\text{CO}_2\text{Et})_2(\text{OAg})$ and EtI Gives no red colour with FeCl_3 Boiled with water it changes to the ethyl derivative of meconic acid (q v) Not acted upon by bromine*

Mono-amide

$\text{C}_2\text{H}_3\text{O}_2(\text{CONH}_2)(\text{CO}_2\text{H})(\text{OH})$ aq **Meconamic acid** From the above by the action of aqueous NH_3 , followed by HCl Crystallises in hard lumps from water Not decomposed by cold NaOH , converted by boiling NaOH into meconate **Copper salt** $\text{C}_2\text{H}_3\text{O}_2\text{Cu}$ 2aq

Basic ammonium salt of amide $\text{C}_2\text{H}_3\text{O}_2(\text{CONH}_2)(\text{CO}_2\text{NH}_2)(\text{ONH}_2)$ This yellow pp is the first product of the action of NH_3 upon mono ethylic meconate

Di amide $\text{C}_2\text{H}_3\text{O}_2(\text{OH})(\text{CONH}_2)_2$ From the diethyl ether and boiling aqueous NH_3 (How) Powder, sl sol cold water

Oxim $\text{C}_2\text{H}_3\text{O}_2\text{NH}$ Formed by treating meconic acid with hydroxylamine hydrochloride (Oderheimer, *B* 17, 2081) Small colourless needles (containing H_2O) V sol water, sl sol alcohol, ether, and chloroform, insol ligroine Decomposes suddenly at 190° It gives a red colour with FeCl_3 It reduces Fehling's solution By boiling with HCl hydroxylamine is split off— $\text{A}''\text{Na}_2$ colourless crystals— $\text{A}''\text{Ag}$, aq white sparingly soluble pp— $\text{A}''\text{Ba}$ 10aq sparingly soluble concentric needles— $\text{A}''\text{Ca}$ 2aq, sparingly soluble needles

Hexahydrate $\text{C}_2\text{H}_3\text{O}_2$, **Hydromeconic acid** Obtained by reducing meconic acid suspended in water by adding sodium amalgam (Korff, *A* 138, 191) Separated by decomposing the lead salt by H_2S and evaporating the filtrate Strongly acid syrup, v sol water, m sol alcohol, insol ether Ppd as deliquescent flocks on adding ether to its alcoholic solution Not affected by HI Gives no colour with FeCl_3 — BaA'' 2aq amorphous pp, sol water, insol alcohol— PbA'' 1½aq amorphous pp— $\text{Ag}_2\text{A}''$ ½aq white granular pp

Reference—PYROMECONIC ACID AND PYROMECONAZONIC ACID

MECONIDINE $\text{C}_{21}\text{H}_{29}\text{NO}_4$, [58°] An alkaloid contained in the aqueous extract of opium (Hesse, *A* 153, 47) The aqueous extract is ppd by Na_2CO_3 , the pp dissolved in ether, the ethereal solution shaken with dilute acetic acid, and the acid solution poured into aqueous NaOH After 24 hours the pp of thebain and papaverine is removed by filtration, the filtrate neutralised by HCl , rendered alkaline by NH_3 , and shaken with chloroform The chloroform is then shaken with acetic acid, and the acid solution exactly neutralised by ammonia, which ppts lanthopine The filtrate is mixed with KOH and shaken with ether Codamine and laudanum separate, and the mother liquor is then shaken with dilute acetic acid, the solution saturated with NaCl , the ppd meconidine hydrochloride decomposed by NaHCO_3 , and the base extracted with ether and dried at 90°

Properties—Brownish yellow transparent amorphous mass Cannot be sublimed Tasteless Insol water, v sol alcohol, ether, benzene, chloroform, and acetone Its alcoholic solution turns red litmus blue Sl sol NH_4Aq , v sol NaOHAq Can be extracted by ether from its solution in ammonia but not from that in caustic soda Its solution in dilute H_2SO_4 becomes rose coloured in a few minutes, and purple red on standing for some time, or immediately on boiling Conc H_2SO_4 gives an olive-green solution Conc HNO_3 colours it orange red The dilute solutions of the salts have an intensely bitter taste— $\text{B}'\text{H}_2\text{PtCl}_6$ yellow amorphous pp which soon turns reddish The aurochloride is a dingy yellow amorphous pp

MECONIN $\text{C}_{11}\text{H}_{13}\text{O}_6$, &c

$\text{C}_2\text{H}_3(\text{OMe})_2 < \text{CO} > \text{O}$. [1.6.3] **Anhydride of**

Meconic acid. *Opranyl* Mol w 194 [99°] (M & F), [102.5°] (Wegscheider, M 3, 351, Prinz, J pr [2] 24, 371) S 4 in the cold, 5 at 100°. A neutral substance existing in opium (Dublanc, A Ch [2] 49, 17, Couerbe, A Ch 49, 11, 50, 337, 59, 148) It may also be extracted by ether from the root of *Hydrastis canadensis* (Freund, B 22, 459)

Formation—1 Together with cotarnine, opianic acid, and hemipic acid, by the action of warm dilute nitric acid on narcotine (Anderson, Tr E 20, 347, 21, 204)—2 From opianic acid by the action of sodium-alumalgar, or of zinc and H₂SO₄ (Matthiessen & Foster, C J 16, 849)—3 Together with hemipic acid by the action of caustic alkalis on opianic acid (M & F)

Preparation—1 A concentrated aqueous extract of opium is pptd by dilute ammonia, and the filtrate evaporated to crystallisation. The crystals are extracted with alcohol, which after evaporation deposits crystals of meconin, which are recrystallised from water and ether successively (Couerbe)—2 The aqueous extract of opium is precipitated by chloride of calcium, the precipitated meconate of calcium is filtered, the filtrate evaporated to the crystallising point, and separated from the deposited hydrochloride of morphine, and the dark mother liquor is diluted with water, filtered from the flocks which separate, and treated with ammonia, which precipitates narcotine, thebaine, and a large quantity of resin. The filtrate is mixed with acetate of lead the excess of lead is removed from the filtered liquid by dilute sulphuric acid, and the filtrate is neutralised with ammonia, and evaporated to the crystallising point at a moderate heat, whereupon narcotine separates out, and then sal ammoniac by further concentration. The mother liquor is repeatedly digested with $\frac{1}{2}$ vol ether at 26°, and the ether is distilled off from the extracts, a brown syrup then remaining. On treating this syrup with dilute hydrochloric acid, papaverine dissolves, and meconin remains in the form of a dark-grey crystalline powder, which, to free it from resin and purify it completely, must be several times crystallised from boiling water, with addition of animal charcoal (Anderson)

Properties—Colourless hexagonal prisms. Appears tasteless at first, but afterwards acid. May be sublimed. Sol cold water, m sol alcohol and ether. Sol KOHAq, nearly insol NH₄Aq. Inactive. Its aqueous solution ppts lead subacetate but not lead acetate. Dilute H₂SO₄ forms a colourless solution which becomes dark green when evaporated (Couerbe). Conc H₂SO₄ forms a colourless solution which becomes purple on heating.

Reactions—1 Conc HClAq at 100° gives MeCl and methyl-normeconin C₁₀H₇O₄ (M & F). HI acts in like manner.—2 Baryta water dissolves meconin forming 'barium meconinate' (C₁₀H₇(OMe)₂(CH₂OH)CO₂)₂ Ba. This salt crystallises in needles, but the free acid splits up at once into water and its anhydride meconin (Hessert, B 11, 240, Prinz, J pr [2] 24, 373).—3 Potash-fusion forms methyl-normeconin C₉H₇O₄ [125°] and, finally, protocatechuic acid.—4 Oxidised by MnO₂ and dilute H₂SO₄ to opianic acid.—5. KMnO₄ oxidises it to hemipic acid [180°].

Chloro-meconin C₁₀H₇ClO₄ [175°] Obtained by passing chlorine into a cold saturated aqueous solution of meconin (Anderson, A 98, 47). Colourless needles. May be sublimed. Sol cold water, v sol alcohol and ether. Hot H₂SO₄ gives a greenish blue colour.

Bromo-meconin C₁₀H₇BrO₄ [167°] (Anderson), [177°] (Salomon, B 20, 888). From meconin and bromine-water. Colourless needles, sl sol water.

Iodo-meconin C₁₀H₇IO₄ [112°] From meconin and chloride of iodine (A). Needles, nearly insol water, m sol alcohol and ether.

Nitro-meconin C₁₀H₇(NO₂)O₄ [158°] From meconin and HNO₃. White needles (from alcohol).

Amido-meconin C₁₀H₇(NH₂)O₄ [171°] Obtained by reducing nitro-meconin with iron and acetic acid (S). M sol hot benzene.

Methyl-normeconin C₉H₇O₄ + e

C₉H₇(OH)(OMe) < $\begin{matrix} \text{CO} \\ \text{CH} \end{matrix}$ > O [125°] Obtained

by heating meconin with conc HClAq (Matthiessen & Foster), by heating meconin with KCy at 180° (Bowman, B 20, 890), or by potash fusion from meconin or narcotine (Beckett & Wright, J 1876, 810). Monoclinic prisms, v sol hot water and alcohol, sl sol ether. FeCl₃ colours it blue. It reduces silver salts in the cold. Potash fusion converts it into protocatechuic acid—CaA'—BaA'.

Meconin acetic acid C₁₁H₁₁O₆ + e

C₁₀H₇(OMe) < $\begin{matrix} \text{CO} \\ \text{CH} \end{matrix}$ > O [167°] Obtained

by heating opianic acid with a mixture of malonic acid, acetic acid, and sodium acetate for 10 hours at 100° (Liebermann & Kleemann, B 19, 2290). Glistening needles. By boiling with baryta water it is converted into opianyl acetic acid C₁₀H₇(OMe)(CO₂H)CH(OH)CH CO₂H. By heating with HI it is dimethylated, giving

C₁₀H₇(OH) < $\begin{matrix} \text{CO} \\ \text{CH} \end{matrix}$ > O [228°], of which the ethyl ether melts at 181°.

Salts—A'A₂Ca white slightly soluble crystals. —A'A₂Cu needles, sl. sol water. —A'A₂Cu* blue crystalline pp.

Methyl ether A'Me [124°], glistening plates.

Ethyl ether A'Et [83°], plates, sol alcohol, ether, and hot water.

Nitro meconin acetic acid

C₁₀H(NO₂)OMe < $\begin{matrix} \text{CO} \\ \text{CH} \end{matrix}$ > O [176°] Nearly

colourless crystals. Obtained by nitration of meconin acetic acid. It dissolves in cold H₂SO₄ with a yellow colour, which becomes red on warming from formation of an indigo derivative. By tin and HCl it is reduced to the lactone of (Py 1.8)-di-oxy-(B'2.8) di methoxy-di hydroquinoline-(B 1)-carboxylic acid.

C₉H(OMe) < $\begin{matrix} \text{CO} \\ \text{CH} \end{matrix}$ > O [256°].

Salts—A'A₂Ca. yellow needles. —A'A₂G* curdy pp. —A'A₂Cu* : green pp.

Ethyl ether AEt [129°], glistening needles, insol water, sol alcohol and benzene (Liebemann & Kleemann, *B* 19, 2295)

ψ **Meconin** $C_8H_4(OMe)_2 \langle \frac{CH}{CO} \rangle O$ [163°] ?

Di methyl derivative of di oxy phthalide [124°] When hemipimide, the imide of hemipic acid $C_8H_4(OMe)_2 \langle \frac{CO}{CO} \rangle NH$, is heated with tin and hydrochloric acid it is reduced to hemipimidine $C_8H_4(OMe)_2 \langle \frac{CH}{CO} \rangle NH$ [181°], which yields a

nitroso derivative • $C_8H_4(OMe)_2 \langle \frac{CH}{CO} \rangle N NO$ [156°], which on treatment with dilute NaOH in the cold yields pseudo meconin (Salomon, *B* 20, 883) Obtained also by boiling hemipimide with zinc dust and acetic acid Long colourless needles (from water) Sl sol cold water, sol benzene, alcohol, and ether Unlike meconin it is not affected by boiling with dilute H₂SO₄ and MnO₂. Dilute HNO₃ at 150° forms nitro hemipic acid and nitro ψ meconin, whereas meconin yields only nitro meconin Fusion with KOH or KCy does not affect ψ meconin

Bromo ψ meconin $C_{10}H_6BrO$, [142°] From ψ meconin and bromine White flocculent pp, sol benzene, insol petroleum

Nitro ψ meconin $C_{11}H_6(NO_2)_2O$, [166°] From ψ meconin and fuming HNO₃ Yellow needles, which yield oxalic acid on further treatment with nitric acid

Amido ψ meconin $C_{10}H_6(NH_2)_2O$, [165°] Obtained by reducing the preceding More basic than amido meconin

MECONOISIN $C_{15}H_{10}O$, [88°] S 37 Occurs in opium, and found in the mother liquor after separation of meconin When this is allowed to stand, crystals are deposited, which are washed with alcohol and recrystallised from water (T a H Smith, *Ph* [3] 8, 981) Large, leaf shaped crystals, v e sol hot water It gives a green colour when heated with dilute H₂SO₄

MEDULLIC ACID $C_{15}H_{22}O_2$, [72.5°] A fatty acid said to be produced, together with stearic and palmitic acids, by the saponification of beef-marrow (Eylerts, *Ar Ph* [2] 104, 129)

MELAM v CYANIC ACIDS

MELAMINE v *Cyanuramide* in the article CYANIC ACIDS

MELAMPYRITE v DULCITE

MELANILINE v DI PHENYL GUANIDINE

MELANIN C 60, H 4.8, N 10.8, ash 2.2 A black pigment covering the choroid membrane of the eye (Scherer, *A* 40, 63) Insol water, alcohol, and ether

Phymatorhusin C 55.7, H 6.0, N 12.3, S 8 to 9, Fe 0.7 to 2 A pigment occurring in melanotic urine and tumours It is obtained by ppg with baryta, dissolving in Na₂CO₃, and ppg with dilute H₂SO₄ (Berdez a Nencki, *J Th* 1886, 477, Möerner, *H* 11, 81) It is a brownish-black amorphous powder, insol water, alcohol, ether, chloroform, and dilute mineral acids, v e sol ammonia, aqueous NaOH, Na₂HPO₄, and Na₂CO₃ Ppd from its solution in NaOH by baryta, MgSO₄, and BaCl₂ With potash fusion it gives skatole, volatile fatty acids, nitriles, KCy, and K₂S Hot H₂SO₄ forms pyridine Phymatorhusin is accompanied by another black substance, which differs from it in being soluble

in 50-75 p c acetic acid. It contains 59 p c of sulphur and 2 p c Fe

Hippomelanin C 53.5-55.6, H 2.7-3.9, N 10.5-10.9, S 2.8-3.0 Occurs in melanotic tumours of horses May be obtained by diluting the emulsion of a melanotic spleen with water and adding CaCl₂ and Na₂HPO₄ The pp is washed at 40°, and then treated with a digestive fluid until the solution ceases to give a reaction for peptones The residue is washed with aqueous soda, alcohol and ether (Miura, *C C* 1887, 250). Brownish black powder, insol water, alcohol, and ether Dissolves on warming in dilute acids and alkalis Potash fusion gives KCy, succinic acid, formic acid, and hippomelanin acid Hippomelanin acid is a black amorphous body, sol ammonia, and reppd by HCl It contains less S and more C than the melanin (Nencki a Sieber, *C C* 1888, 587) The black pigment in dark hair and in bird's feathers after purifying by alcoholic NH₃ and dilute H₂SO₄ may be represented by the formula $C_{10}H_7N_2O_4$ (Hodgkinson a Sorby, *J* 1876, 936) Black powder Not affected by dilute acids and alkalis

Sepiatic acid C 56.3, H 3.6, N 12.3, S 5, O 27.2 Obtained by digesting the pigment from the ink bag of *sepiæ* with 15 pts of 10 p c potash Sol alkalis, ppd from ammoniacal solution by ammonia zinc chloride or copper sulphate (Nencki a Sieber)

MELANTHIN $C_{20}H_{14}O$, [205°] Occurs in the seeds of *Nigella sativa* (Greenish, *Ph* [3] 10, 909, 1013) Prepared by extracting the seeds with alcohol, evaporating the extract, dissolving the pp in alcohol, and fractionally ppg with water Minute grey crystals (from alcohol) Insol water, benzene, CS₂, and light petroleum, v sol alcohol, sol alkalis, sl sol chloroform Conc H₂SO₄ gives a red colouration H₂SO₄ and sugar give a violet blue colour Boiling dilute HCl splits it up into a sugar and melanthigenin $C_{11}H_{12}O_2$, which forms minute crystals, sl sol water

MELANURENIC ACID v AMMELIDE

MELEM v CYANIC ACIDS

MELENE $C_{12}H_{10}$, [62°] (370°-380°) S G 89 VD 10-11.8 S (alcohol) 13 in the cold, 3.6 at 78° An olefine (?) produced by the dry distillation of bees' wax (Ettling, *A* 2, 252, Lewy, *A Ch* [3] 5, 395, Brodie, *A* 71, 156) — White nacreous plates (from ether) Insol water, sl sol cold alcohol, v sol ether Not attacked by cold H₂SO₄, slightly attacked by boiling HNO₃ Attacked by chlorine

MELEZITOSE $C_{12}H_{20}O_{11}$, [148°] $[\alpha]_D = 94^\circ$ (B), 88.5° (V) A sugar discovered by Bonastre in the manna of Briançon which exudes from the young branches of 'mélèze' (*Pinus Larix*) (Berthelot, *A Ch* [3] 65, 282) It occurs also in 'taranjoline' or Turkestan manna (Villiers, *Bl* [2] 27, 98, Alekhine, *Bl* [2] 46, 824) Obtained by extracting the Briançon manna with boiling alcohol, and evaporating After a few weeks melezitose separates, it is then recrystallised from alcohol Monoclinic crystals containing aq (V), or anhydrous crystals (A) About as sweet as glucose Dextrorotatory V sol water, nearly insol cold, sl sol boiling, alcohol, insol ether Its aqueous solution is ppd by ammoniacal lead acetate Boiling dilute H₂SO₄ forms glucose It is turned brown by alkalis.

It does not reduce Fehling's solution Does not ferment with yeast It forms a compound with phenyl hydrazine It gives an octo acetyl derivative.

MELIDO-ACETIC ACID $C_8H_5N_2O_2$ *18* $(CN)_2N_2H_2CH_2CO_2H$ Formed by treating cyanamide with chloroacetic ether and NaOEt (Drechsel, *J pr* [2] 11, 332) Amorphous mass, but obtained in a crystalline state by ppg its ammonium salt with HCl Decomposed by heat without previous fusion Insol alcohol and ether, v sl sol cold water Sol aqueous HClAq, baryta, and KOHAq, but insol NH₄Aq — HA'HCl needles, sl sol cold water — HA'HNO₃Aq — AgA'HNO₃Aq — (HA')₂H₂SO₄ 4aq

MELILOTIC ACID *v* OXY PHENYL PROPIONIC ACID

MELILOTOL $C_{10}H_{10}O_2$ (?) An oil found, together with coumarin, in the yellow melilot (*Melilotus officinalis*) Extracted by distilling the plant, when in flower, with steam, and extracting the distillate with ether (Phipson, *C N* 32, 25, *C R* 86, 830) Liquid, v sl sol water, alcohol, and ether Has an agreeable odour When boiled with conc KOHAq it yields oxy phenyl propionic (mehlotic) acid $C_8H_{10}O_2$ Melilot is perhaps identical with the lactone of

MELINOIN - TRI - SULPHONIC ACID $C_8H_5O_3(SO_3H)_3$

Formation — 1 By warming a mixture of *p* oxy benzoic aldehyde, (8) naphthol, and H₂SO₄ 2 From benzoic aldehyde, (8) naphthol, and H₂SO₄ — 3 By heating Baeyer's condensation product $C_8H_5O_2$ (from benzoic aldehyde and (8) naphthol) with H₂SO₄ (Trzciński, *B* 16, 2835, 17, 500) — Yellow crystalline powder Insol absolute alcohol, tolerably sol water, the dilute solution being of a rose red colour with a green fluorescence It dissolves in strong H₂SO₄ or HNO₃ with a splendid green fluorescence, and is not attacked even on boiling It forms unstable compounds with HCl and H₂SO₄, although it is itself a strong acid

Salts — A'''K, easily soluble fine colourless needles — A'''Ca, aq colourless soluble crystals — A'''Ba, sparingly soluble white amorphous pp or microscopic needles

MELISSIC ACID $C_{10}H_{16}O_2$ *18* $C_{10}H_{16}CO_2H$, or $C_7H_{12}O_2$ *18* $C_3H_7CO_2H$ [90°] Occurs in bees' wax (Natzger, *A* 224, 225) Formed by heating the myricyl alcohol of bees' wax with soda lime at 270°-300° in absence of air (Brodie, *A* 71, 156, Von Peverling, *A* 183, 344, Sturcke, *A* 223, 295, Schwalb, *A* 235, 106) Silky scales, composed of minute needles Sol alcohol, light petroleum, chloroform, and CS₂, sl sol ether According to Schalleff (*B* 12, 697) melissic acid is a mixture of acids

Salts — PbA₂ [119°] Insol alcohol and ether, sl sol boiling toluene, chloroform, and glacial acetic acid — MgA₂ — CaA₂ — AgA₂ [95°], amorphous pp

Methyl ether MeA' [71°] Needles (from lignin)

Ethyl ether EtA' [70°] (Schwalb), [73°] (P) Needles (from alcohol) Split up on heating into ethylene and the free acid

Isoamyl ether C₅H₁₁A' [69°].

MELISSYL ALCOHOL *v* MYRICYL ALCOHOL.

MELITOSE *v* RAFFINOSE and SUGARS

MELLITIC ACID $C_{12}H_6O_{12}$ *18* $C_6(CO_2H)_6$

Mellitic acid Benzene hexa-carboxylic acid. Mol w 342 H G v 790,800 H C p 788,200 H F 546,800 (Stohmann, Kleber, a Langbein, *J pr* [2] 40, 141) Heat of neutralisation 84,034 (Gal a Werner, *Bl* [2] 47, 162)

Occurrence — As aluminium mellitate in honey stone or mellite (Klaproth, *A D* 1799, Baeyer, *A Suppl* 6, 1)

Formation — 1 By the oxidation of hexamethyl benzene by cold alkaline KMnO₄ (Friedel a Kratts, *A Ch* [6] 1, 470) — 2 By the oxidation of charcoal by KMnO₄ (Schulze, *B* 4, 802, 806) — 3 By the electrolysis of acidified water or of KOH using a positive electrode of gas carbon (Bartoli a Papasogli, *G* 11, 468, *C C* 1831, 327) — 4 In very small quantity by oxidising coal, animal charcoal, or lampblack by alkaline NaOCl (Bartoli a Papasogli, *G* 15, 446)

Preparation — Powdered honey stone is boiled with ammonium carbonate, ammonia is added, and the filtrate evaporated to crystallisation The ammonium mellitate is recrystallised with addition of a little ammonia, dissolved in water, ppd by lead acetate, and the pp decomposed by H₂S (Wohler, *A* 37, 263, Schwarz, *A* 66, 47, Claus, *B* 10, 559)

Properties — Stellate groups of delicate silky needles (from alcohol), v sol water and alcohol Decomposed by heat into CO and pyromellitic acid $C_{10}H_4O_8$ (Erdmann, *J pr* 52, 432), which solidifies in the neck of the retort as a radio-crystalline mass When strongly heated with glycerin it yields CO₂ and trimelic acid $C_6H_4O_6$ When heated to redness with soda lime it yields benzene (Baeyer, *A Suppl* 7, 5) Not decomposed by boiling HNO₃, sulphuric acid, HIAq, chlorine, or bromine When its aqueous solution is electrolysed, CO₂, hydrogen, CO, and oxygen are given off (Bunge, *J R* 12, 421)

Salts — (NH₄)₂C₁₂O₁₂ 3aq trimetric crystals (Schwarz, *A* 66, 47) Decomposed at 150° with formation of paramide and ammonium euchoate — (NH₄)₂H₂C₁₂O₁₂ 4aq trimetric prisms From ammonio cupric mellitate and H₂S — K₂A^{VI} 9aq trimetric crystals — K₂H₂A^{VI} 8aq — K₂H₂A^{VI} 6aq large prisms, more soluble in water than the normal potassium salt — (K₂H₂A^{VI})(KNO₃)₂ 9aq (?) — Na₂A^{VI} 12aq needles (from a hot conc solution) — Na₂A^{VI} 18aq large striated triclinic crystals — Ba₂A^{VI} 3aq white gelatinous pp, changing to scales — Mg₂A^{VI} 18aq crystalline mass — Mg(NH₄)₂A^{VI} 15aq large glassy prisms — Zn₂A^{VI} 15aq — Zn₂A^{VI} 9aq — Mn₂A^{VI} 18aq minute needles, more sol cold than hot water S (hot water) 125 — Co₂A^{VI} 18aq minute prisms (from boiling water) — Ni₂A^{VI} 24aq v sl sol water — Al₂A^{VI} 18aq *Mellite* S G 16 SH 336 (Bartoli, *G* 14, 105) Occurs in lignite at Asten in Thuringia, Bilin in Bohemia, and near Walschau in Moravia Massive nodules Dimetric crystals *a c* = 1 745 — Fe₂A^{VI}Fe₂O₉ 9aq minute lemon yellow crystals, v sl sol water — Cu₂A^{VI} 12aq From boiling mellitic acid and cupric acetate Amorphous pp, becoming crystalline — Cu₂H₂A^{VI} 12aq — Cu₂(NH₄)₂A^{VI} 12aq from cupric sulphate and ammonium mellitate. — Hg₂A^{VI} 6aq (dried at 100°), granular mass —

$\text{Hg}_2\text{A}^{\text{VI}}$ 6aq (dried at 100°). granular pp — $\text{Pb}_2\text{A}^{\text{VI}}$ (dried at 180°) bulky white pp — $\text{Pd}_2\text{A}^{\text{VI}}(\text{NH}_3)_2$ 6aq colourless trimetric crystals (Karmrod, *A* 81, 164) — $\text{Ag}_2\text{A}^{\text{VI}}$ white crystal line powder (Wöhler, *A* 30, 1)

Methyl ether $\text{Me}_2\text{A}^{\text{VI}}$ [187°] From silver mellitate and MeI (Kraut, *J* 1862, 281, *A* 177, 273) Plates H C 1,825,600 HF 487,400 (Stohmann, *J pr* [2] 40, 350)

Ethyl ether $\text{Et}_2\text{A}^{\text{VI}}$ [73°]

Isoamyl ether $(\text{C}_4\text{H}_9)_2\text{A}^{\text{VI}}$ Oil

Chloride $\text{C}_6(\text{COCl})_2$ [190°] (Claus, *B* 10, 561) Formed, together with an oxychloride $\text{C}_6\text{O}_2\text{Cl}_2$, from PCl_5 and mellitic acid. Hard vitreous prisms (from ether) Sublimes in laminae at 240° . Slowly decomposed by water into HCl and mellitic acid.

Tri imide $\text{C}_{12}\text{H}_2\text{N}_2\text{O}_8$ *se*

$\text{C}_6\left\{\begin{array}{c} \text{CO} \\ \text{CO} \end{array}\right\} \text{NH}$ *se* *Paramide* Formed, together with euchroic acid, by heating ammonium mellitate at 160° as long as NH_3 escapes. Water extracts ammonium euchroate from the residue leaving paramide undissolved (Wöhler, *A* 37, 268, Schwarz, *A* 66, 52). White amorphous powder, insol water and alcohol. Sol H_2SO_4 , but reprecipitated by water. Boiling with water slowly converts it into $(\text{NH}_4)_2\text{H}_2\text{C}_6\text{O}_{12}$. Alkalis convert it first into euchroic and then into mellitic acid. AgNO_3 forms in its ammoniacal solution a gelatinous pp which gives off NH_3 when heated, leaving $\text{Ag}_2\text{N}_2\text{C}_{12}\text{O}_{12}$. An ammoniacal solution of paramide dropped into HClAq gives a white crystalline pp called 'paramic acid' $\text{C}_{12}\text{H}_2\text{N}_2\text{O}_8$ (?) or

$\text{CO}(\text{NH}_2)_2 > \text{C}_6\left\{\begin{array}{c} \text{CO} \\ \text{CO} \end{array}\right\} \text{NH}$ *se*

Tri phenyl tri imide

$\text{C}_6\left\{\begin{array}{c} \text{CO} \\ \text{CO} \end{array}\right\} \text{NPh}$ *se* Formed by heating mellitic acid or ammonium mellitate (1 mol) with aniline (6 mols) at 160° for 7 hours (Hotte, *J pr* [2] 32, 238). White amorphous mass

Di imide $\text{C}_{12}\text{H}_2\text{N}_2\text{O}_8$ *se*

$(\text{CO}_2\text{H})_2\text{C}_6\left\{\begin{array}{c} \text{CO} \\ \text{CO} \end{array}\right\} \text{NH}$ *se* *Euchroic acid*. Prepared by heating ammonium mellitate at 160° for several hours, dissolving in water, and adding HCl to the hot solution. The crystals which separate on cooling are recrystallised from water (Wöhler, *P* 52, 610, Schwarz, *A* 66, 49). Small prisms (containing 2aq), al sol cold water. Strongly acid. Melts about 280° . Euchroic acid is not decomposed by boiling water or HClAq . When a solution of euchroic acid is treated with zinc the metal becomes covered with a dark blue deposit of 'euchrone'. This deposit detaches itself when the zinc is immersed in dilute HClAq . After drying, euchrone is a black mass which becomes colourless when heated in air, being re-oxidised to euchroic acid. Euchrone forms a deep purple solution in NH_4Aq or KOH Aq , but the solution is quickly decolourised by the air. When a solution of euchroic acid is electrolysed, the negative platinum becomes coated with the blue deposit.

Salts — $(\text{NH}_4)_2\text{C}_{12}\text{H}_2\text{N}_2\text{O}_8$ white crusts — An acid ammonium salt separates from hot solutions in yellowish crystals — BA^{VI} 6aq pale-yellow powder — PbA^{VI} 6aq — PbA^{VI} 6aq — $\text{Ag}_2\text{A}^{\text{VI}}$ sulphur-yellow powder.

Hexahydrate $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_6$ *Hydromellitic acid* Formed by treating an ammoniacal solution of mellitic acid with sodium amalgam, neutralising with acetic acid, ppg by lead acetate, and decomposing the pp with H_2S (Baeyer, *A Suppl* 7, 16). Formed also in the electrolysis of aqueous KOH with a positive electrode of carbon (Bartoli a Papasogli, *C* 1881, 327). Hygroscopic syrup, v e sol water. By heating with H_2SO_4 (5 pts) there is formed, together with CO_2 and SO_2 , trimelic acid $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_3$, prehnitic acid $\text{C}_6\text{H}_2(\text{CO}_2\text{H})_4$, mellophanic acid $\text{C}_6\text{H}_2(\text{CO}_2\text{H})_4$, and prehnomalic acid $\text{C}_{10}\text{H}_8\text{O}_8$.

Salts — The alkaline salts are gummy, v e sol water — The calcium salt is more soluble in hot than in cold water — $\text{Pb}_2\text{A}^{\text{VI}}$ (dried at 150°) Amorphous pp — $\text{Ag}_2\text{A}^{\text{VI}}$ amorphous pp

Isohexahydrate $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_6$ *Isohydromellitic acid* Formed by heating the preceding hexahydrate with conc HClAq for 3 hours at 180° (Baeyer) Prisms (from water) v sol water, but ppd on addition of HCl . Not affected by heating with fuming HClAq at 300° . Decomposed in the same manner as its isomeride when heated with H_2SO_4 . Chromic acid mixture oxidises it to acetic acid and CO_2 . — $\text{Pb}_2\text{A}^{\text{VI}}$

Methyl ether of the Isohexahydrate $\text{Me}_2\text{C}_{12}\text{H}_2\text{O}_{12}$ [125°] Needles, v e sol also hol

References — HEMI MELLITIC ACID, PYROMELLITIC ACID

TRIMELLITIC ACID $\text{C}_6\text{H}_2\text{O}_8$ *se*

$\text{C}_6\text{H}_2(\text{CO}_2\text{H})_3$ [1 2 4] *Benzene tricarboxylic acid* Mol w 210 [218°]

Formation — 1 Together with isophthalic acid and pyromellitic anhydride by heating the tetrahydride of pyromellitic acid $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_4$ with 5 pts of H_2SO_4 (Baeyer, *A Suppl* 7, 40) — 2 By oxidising the acid $\text{C}_6\text{H}_4\text{Me}(\text{CO}_2\text{H})_2$, prepared from ψ cumene, by KMnO_4 (Krinno, *B* 10, 1491) — 3 By oxidising alizarin carboxylic acid with dilute HNO_3 (Hammerschlag, *B* 11, 88) — 4 By oxidising the acid $\text{C}_6\text{H}_2\text{Me}(\text{C}_6\text{H}_4)\text{CO}_2\text{H}$ with dilute nitric acid (S G 1 12) at 240° (Effront, *B* 17, 2338) — 5 By the action of cuprous cyanide upon the diazo compound from amido terephthalic acid, and saponification of the product with aqueous KOH (Ahrens, *B* 19, 1634) — 6 By heating mono potassic (8) sulphophthalate with sodium formate, 1-ophthalic acid being also formed (Graebe a Rce, *C J* 49, 532)

Preparation — 100 g pulverised colophony and 2 litres of nitric acid (1 vol commercial acid to 2 vols water) are introduced into a retort with its beak directed upwards, and the liquid is heated to boiling, whereupon the colophony melts, and is quickly attacked, with copious evolution of red vapours, and converted into an orange yellow viscid mass. After the boiling has been continued for 6 or 8 hours, fresh resin and strong nitric acid are added alternately, till about 1 kg resin has been introduced, the contents of the retort being kept in constant ebullition, this process takes about a fortnight. The resulting wine yellow liquid, which on addition of water should merely show turbidity, and not yield any lumpy precipitate, is then distilled off till the remaining liquid begins to froth, and

this liquid, while still hot, is poured into a ten fold volume of cold water, decanted after twenty-four hours from the varnish like resin which separates, and evaporated to a syrupy consistence. The whole then solidifies after a while to a thick crystalline pulp, which may be freed from the syrupy mother-liquor by means of an aspirator and porous earthenware plates, and afterwards boiled with water. The extract on cooling deposits isophthalic acid in slender needles, and on further concentration, first a little more of the same acid and then trimellitic acid, which may be purified by solution in alcohol and crystallisation from water. 30 g of trimellitic acid may be thus obtained from 50 g of resin (Schreder, *A* 172, 93).

Properties—Rosettes of small needles, m sol water and ether. When heated above its melting point the anhydride distils over, condensing in concentrically arranged groups of needles. On fusion with NaOH it gives benzene and diphenyl (Barth & Schreder, *B* 12, 1257). It also yields benzene when distilled with lime.

Salts— $\text{Ba}_2\text{A}'''$, 4aq (when air dried). Gives off 3aq at 160° . Sl sol water— $\text{Ba}_2\text{A}'''$, 3aq (when dried over H_2SO_4)— $\text{Ag}_2\text{A}'''$ white pp, not much affected by light. Sl sol water.

Anhydride $\text{C}_6\text{H}_2(\text{CO}_2\text{H})_2 \xrightarrow{\text{CO}} \text{CO}_2\text{O}$ [158°]

Formed by heating the acid (Baeyer, *A* 166, 340). Crystalline mass, sl sol cold, v sol hot, water.

Reference—SULPHO TRIMELLITIC ACID

MELLITYL ALCOHOL v **PENTA METHYL BENZYL ALCOHOL**

MELLOGEN $\text{C}_{11}\text{H}_{10}\text{O}_4$. On the electrolysis of water by a battery of 1,200 Daniell's cells, the anode being gas carbon, the liquid becomes of an inky colour, and there is deposited in the voltameter a black residue. This is washed with water until the filtrate is quite colourless, from the washings the mellogen is ppd with a small quantity of dilute hydrochloric acid (Bartoli & Papasogli, *G* 11, 468, 12, 117, 13, 37, 15, 464, *C* R 94, 1839, *A* Ch [6] 7, 364). A black solid, of conchoidal fracture, sol water and alkalis, insol alcohols and hydrocarbon, and in most mineral acids and salts. It is not readily combustible, and is converted by oxidising agents, e.g. NaOCl, into mellitic and pyromellitic acid and their hydrides. At ordinary temperatures it has the composition $2\text{C}_{11}\text{H}_{10}\text{O}_4 + 3\text{H}_2\text{O}$, at 100° it may be represented by $2\text{C}_{11}\text{H}_{10}\text{O}_4 \cdot \text{H}_2\text{O}$. The aqueous solution of mellogen is dark coloured, and is ppd by acids and by many salts. With baryta mellogen gives an insoluble pp. Nitric acid (8 G 136) oxidises mellogen forming an amorphous compound $\text{C}_{11}\text{H}_8\text{O}_5$, sol water, alcohol, and ether, a soluble acid $\text{C}_{11}\text{H}_8\text{O}_6$, 2aq, forming the salts $\text{Ba}_2(\text{C}_{11}\text{H}_8\text{O}_6)_2$ and $\text{Ag}_2\text{C}_{11}\text{H}_8\text{O}_6$, and a black compound resembling mellogen.

MELLONE v **CYANIC ACIDS**

MELLOPHANIC ACID $\text{C}_{12}\text{H}_6\text{O}_8$, $\text{C}_{12}\text{H}_6\text{O}_8$, $\text{C}_{12}\text{H}_6\text{O}_8$ [1 2 3 5]. *Benzene t-tetra carboxylic acid* [238°]. Obtained, together with prehnitic acid $\text{C}_6\text{H}_2(\text{CO}_2\text{H})_4$ [1 2 3 4], by heating the hydride of pyromellitic acid $\text{C}_6\text{H}_2(\text{CO}_2\text{H})_4$ [1 2 4 5] with H_2SO_4 (Baeyer, *A* 166, 327). Formed also by the oxidation of iso-durene $\text{C}_{12}\text{H}_{16}\text{Me}_2$ (Jacobson, *B* 17, 2516). Small four-sided prisms, v sol water, but ppd by HCl from a conc. solu-

tion. Converted into an anhydride on fusion. Calcium acetate gives in hot solutions of the acid a pp which re-dissolves on cooling. Baryta-water gives a pp which becomes crystalline on heating. Lead acetate gives a flocculent pp, insol acetic acid. Sodium amalgam forms a hydride of mellophanic acid.

Anhydride [238°]. Formed by fusing the acid. Insol ether.

MELOLONTHIN $\text{C}_{12}\text{H}_{12}\text{N}_2\text{SO}_4$. Found, together with leucine and hypoxanthine, in cockchafer (*Melolontha vulgaris*). The insects are extracted with water, the extract boiled, ppd with lead subacetate, and the filtrate freed from lead by H_2S and evaporated. The crystals are freed from leucine by treatment with alcohol (Schreiner, *B* 4, 763). 30lbs of cockchafer yield 1.5 g melolonthin. Silky needles (from water), sl sol cold, m sol hot, water, v sl sol dilute alcohol and ether, v sol acids and alkalis. Does not act on light.

MELMESIDINE v **DI MESITYL GUANIDINE**

MENAPHTHYLAMINE $\text{C}_{11}\text{H}_9\text{N}_2$

$\text{C}_{10}\text{H}_7\text{CH}_2\text{NH}_2$. (292°). Formed by treating the amide of (a)-thionaphthoic acid $\text{C}_{10}\text{H}_7\text{CSNH}_2$ with zinc and HCl (Hofmann, *B* 1, 100). Alkaline liquid, readily absorbing CO_2 from the air— B^+HCl long, sparingly soluble crystals— $\text{B}^+\text{H}_2\text{PtCl}_6$ yellow crystalline pp.

MENISPERMINE $\text{C}_{18}\text{H}_{24}\text{N}_2\text{O}_2$ (?) [120°]

Occurs in the seeds of *Menispermum cocculus* (Pelletier & Caventon, *A* Ch [2] 54, 178). To extract the menispermine, the alcoholic extract of the seeds is first treated with cold water, then exhausted with hot acidulated water, the brown solution is ppd by an alkali, and the pp is exhausted with very weak acetic acid, which leaves a brown black mass undissolved. Or the seeds may be made up into a heap, and exhausted with alcohol of specific gravity 0.833, the alcohol distilled off, the residue boiled with water, and the liquid filtered at the boiling heat, it then, on cooling, deposits crystals of picrotoxine, especially if a small quantity of acid has been added. The part insol boiling water is then treated with acidulated water, and ppd by an alkali, a granular pp is thereby formed, from which alcohol extracts a peculiar yellow substance, and the residue is finally dissolved in ether, which deposits menispermine in the crystalline form. The ether leaves undissolved a viscous substance, which may be dissolved in absolute alcohol and the solution, evaporated at 45° , ultimately yields crystals of paramenispermine.

Properties—Prisms, insol water, sol alcohol and ether. Is not poisonous. Its sulphate forms prismatic needles, sol water.

Paramenispermine [250°]. Isomeric with menispermine. Insol water, sl sol ether, v sol boiling alcohol. Dissolves in dilute acids.

MENTHENE $\text{C}_{10}\text{H}_{16}$. Mol w 138 (167.4°) (Atkinson & Yoshida, *C* J 41, 53), (163°) (Oppenheim, *C* J 15, 29). VD 4.94 (calc 4.78). SG 1.814, $d_{20}^{20} 0.8226$, $d_{20}^{20} 0.8073$ (A & Y). CE (0° – 10°) 0.00994, (0° – 60°) 0.0100 [α_D] = +13.25 (A & Y). $R_D 74.0$ Specific refractive energy, 548. Specific dispersive energy, 0313 (Gladstone, *C* J 49, 622). Obtained by distilling menthol (1 pt) with ZnCl_2 (2 pts), or with P_2O_5 (Walter, *A* 32, 288). Formed also by the action

of conc H_2SO_4 on menthol (Beckmann, *A* 250, 358)

Properties—Colourless oil, smelling like cymene, m sol ether and alcohol, v sol benzene, turpentine, and petroleum Dextrorotatory

Reactions—1 Combines with fuming HCl , forming a yellow oil $\text{C}_{10}\text{H}_{19}\text{Cl}$ Combines also with HI , forming $\text{C}_{10}\text{H}_{21}\text{I}$, identical with the product obtained by heating terpinene dihydride $\text{C}_{10}\text{H}_{16}2\text{HI}$ with HI (Bouchardat & Lafont, *C R* 107, 916)—2 Combines with bromine, forming $\text{C}_{10}\text{H}_{18}\text{Br}_2$, which is split up by heat into HBr and cymene (Beckett & Wright, *C J* 29, 1) 3 Fuming nitric acid oxidises it to glutaric acid

MENTHOL $\text{C}_{10}\text{H}_{18}\text{O}$

propyl phenol hexahydride Mol w 156 $[\alpha]_D^{20}$ (212°) VD 5 62 (calc 5 41) SG $\frac{1}{2}$ 890 $[\alpha]_D^{20}$ = -59.3 (Moriya), $[\alpha]_D^{20}$ = -59.6 (Oppenheim), = -49.4 in a 5 p.c. alcoholic solution at 22° (Arth, *A Ch* [6] 7, 438) R_D^{20} = 77.4 in a 21 p.c. benzene solution (Kanonnikoff, *J pr* [2] 31, 348) HC 1,509,100 (Lougounine, *A Ch* [5] 23, 387) Deposited in crystals when the essential oil of peppermint is kept for a long time or cooled to a low temperature (Dumas, *A* 6, 252, Blanchet & Sell, *A* 6, 293; Walter, *A* 32, 288; Kane, *P M* 16, 418; Laurent, *Rev Sci* 14, 341; Oppenheim, *C J* 15, 24) Menthol is imported from Japan in the solid state as 'peppermint camphor' (Moriya, *C J* 39, 77) White crystals, smelling of peppermint, sl sol water, v sol alcohol, ether, CS_2 , HOAc , and fixed and volatile oils Insol aqueous alkalis From alcoholic NaOH it crystallises in long needles Sodium dissolves in it with evolution of hydrogen Conc acids dissolve menthol, but it is reppd on dilution with water Menthol has the refractive and dispersive energy of a saturated compound (Gladstone, *C J* 49, 621) The rate of etherification of menthol by acetic acid is that of a secondary alcohol (Menschutkin, *J R* 13, 569)

Reactions—1 With $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 in sealed tubes at 120° gives an inactive oil 'menthone' (205°), $\text{C}_{10}\text{H}_{18}\text{O}$, SG $\frac{1}{2}$ 9032, sol alcohol, ether, and chloroform—2 Fuming HNO_3 forms an explosive oil, SG $\frac{1}{2}$ 1 061, which may be reduced to a yellow oil $\text{C}_{10}\text{H}_{19}\text{NH}_2$ (185°–190°) 3 Excess of fuming HNO_3 forms an acid, probably glutaric (*q v*)—4 Bromine in acetic acid forms $\text{C}_{10}\text{H}_{17}\text{Br}$ Unstable oil—5 Conc HCl aq at 100° slowly forms menthyl chloride PCl_5 forms the same body—6 ZnCl_2 or P_2O_5 dehydrate menthol, producing menthene—7 KMnO_4 in acid solution forms (8) pimelic acid $\text{C}_8\text{H}_{12}\text{O}_4$, [87°], of which the amide [191°] crystallises from water in prisms (Arth, *A Ch* [6] 7, 440, *C R* 107, 107) Formic, propionic, butyric, and oxymenthyl acids are formed at the same time The oxymenthyl acid $\text{C}_{10}\text{H}_{18}\text{O}_4$ boils at 174° under 15 mm pressure—8 Boiled with HI (SG 1.7) for 3 days it forms a mixture of hydrocarbons chiefly consisting of $\text{C}_{10}\text{H}_{16}$ (168.6°) VD 67.25, $[\alpha]_D^{20}$ = +5.2 SG $\frac{1}{2}$ 8254, $\frac{1}{2}$ 8111, CE (0°–10°) 000929, (0°–60°) 000694 R_D^{20} 78.28 Colourless oil, v sol petroleum or

benzene, less so in alcohol or ether Odour resembles cymene (Atkinson & Yoshida, *C J* 41, 54)—9 Menthol does not react with hydroxylamine (Nageli, *B* 16, 499)—10 On heating with sodium and ether on the water bath, and, after cooling, adding CS_2 , there is formed menthyl-xanthogenic acid $\text{C}_{10}\text{H}_9\text{O CS SH}$, a liquid which undergoes spontaneous decomposition, but forms a yellow crystalline copper salt CuA_2 (Bamberger & Lodter, *B* 23, 213)

Acetyl derivative $\text{C}_{10}\text{H}_{17}\text{OAc}$ *Menthyl acetate* (223°) $[\alpha]_D^{20}$ = -114° From menthol and HOAc at 120° (Oppenheim, *C J* 15, 26) Liquid Not decomposed by cold alkalis, but saponified by alcoholic NaOH at 120°

Butyryl derivative $\text{C}_{10}\text{H}_{17}\text{O CO C}_3\text{H}_7$, *Menthyl butyrate* Obtained by heating menthol with butyric acid at 200° for 30 hours (Oppenheim) (230°–240°) $[\alpha]_D^{20}$ = -89°

Benzoyl derivative $\text{C}_{10}\text{H}_{17}\text{OBz}$ [54°] (230°) $[\alpha]_D^{20}$ = -91° In a one p.c. benzene solution, trimetric crystals partially decomposed on distillation into menthene and benzoic acid (Arth, *A Ch* [6] 7, 479)

Carbamyl derivative $\text{C}_{10}\text{H}_{17}\text{NO}$, *Menthyl carbamate* [165°] $[\alpha]_D^{20}$ = -85° in a 58 p.c. chloroform solution at 21° Formed by passing dry cyanogen into a solution of sodium menthol in dry toluene The product is washed with water and the toluene distilled off The crystalline mass is then recrystallised from alcohol, from which the carbamyl derivative separates in slender prismatic needles (Arth, *C R* 94, 872, 98, 521, *A Ch* [6] 7, 433) Needles, m sol alcohol and benzene Sublimes at 100° Decomposes at about 200°, yielding cyanuric acid Alcoholic KOH forms menthol and potassium cyanate Ac_2O at 130° forms $\text{C}_{10}\text{H}_{17}\text{OAc}$ Benzoic aldehyde and HCl form $(\text{C}_{10}\text{H}_{17}\text{OCO NH})_2\text{CHPh}$ [143°]

Carbonyl derivative $(\text{C}_{10}\text{H}_{17}\text{O})_2\text{CO}$ *Menthyl carbonate* [105°] Obtained in the preparation of the carbamyl derivative by evaporating the alcoholic mother liquor and boiling the residue with water as long as menthol and ammonia come off On cooling, the carbonyl derivative is deposited as a crystalline mass, sol boiling alcohol (Arth) Plates (from alcohol) or prisms (from toluene), v sl sol alcohol, v sol ether and benzene Alcoholic KOH at 100° saponifies it

Phenyl-carbamyl derivative $\text{C}_{10}\text{H}_{17}\text{O CO NHPh}$ *Menthyl phenyl urethane* *Menthyl phenyl carbamate* [111°] From menthol and phenyl cyanate (Leuckart, *B* 20, 116) Silky needles (from hot alcohol)

Succinoyl derivative $\text{C}_{10}\text{H}_{17}\text{O CO CH}_2\text{CH}_2\text{CO}_2\text{H}$ [62°] $[\alpha]_D^{20}$ = -59.6° in a 1.4 p.c. benzene solution Formed by heating menthene (1 mol) with succinic anhydride (1 mol) at 110° (Arth) Acicular crystals, v sol alcohol, v sl sol hot water Its Na and K salts are very deliquescent, the Ca and Ba salts are white pps— $\text{AgC}_{10}\text{H}_{17}\text{O}$, small needles (from hot water)

Succinyl derivative $(\text{C}_{10}\text{H}_{17})_2\text{C}_2\text{H}_2\text{O}_4$ [62°] (220°) $[\alpha]_D^{20}$ = -81.5° in a 1.9 p.c. benzene solution From menthol (1 mol) and succinic acid (2 mols) at 150° Trimetric crystals (from alcohol) Decomposes on distillation into succinic acid and menthene.

Phthaloxyl derivative $C_{18}H_{24}O_4$, *tc* $C_{18}H_{18}O_4$ $COO C_6H_4 CO_2H$ [110°] $[\alpha]_D = -105.6^\circ$ in a 16 p c benzene solution. Formed by heating menthol (1 mol) with phthalic anhydride (1 mol) at 110° (Arth). Minute needles, insol cold water, v sol alcohol and ether. Gives white pps with Ba and Ca salts $-Mg(C_{18}H_{24}O_4)$ laminae, almost insol cold water.

Phthalyl derivative $C_{18}H_{20}O_4$, *tc* $(C_{18}H_{18})_2C_6H_4O_2$ [133°] $[\alpha]_D = -94.7^\circ$ in a 2 p c benzene solution at 20°. From phthalic anhydride (1 mol) and menthene (2 mols) at 140°. Trimetric crystals (from ether), sl sol boiling alcohol.

Menthyl chloride $C_{10}H_{17}Cl$ (c 204°). Obtained by treating menthol with PCl_5 (Walter, *A* 82, 292) or with conc $HClAq$ for a week at 100° (Oppenheim). The same body appears to be formed by heating menthene with fuming $HClAq$ at 120° (Arth, *C R* 97, 323). Light oil, sl sol water, m sol alcohol. Not attacked by alcoholic KOH . With sodium menthol it gives menthene and menthol.

Menthyl bromide $C_{10}H_{17}Br$. From menthol and bromide of phosphorus. Non volatile liquid. Gives with bromine $C_{10}H_{17}Br_2$.

Menthyl iodide $C_{10}H_{17}I$. From menthol and conc $HI Aq$. Liquid, decomposed by alcoholic K_2S into menthene and HI .

Tetra menthyl silicate $Si(OC_{10}H_{19})_4$. [82°] (350°) at 155 mm. Formed by the action of $SiCl_4$ upon menthol, the yield is 75 p c of the theoretical (Hertkorn, *B* 18, 1695). Colourless prisms, v sol ether, benzene, ligroin, chloroform, CS_2 , and warm alcohol, sl sol cold alcohol.

Oxymenthyllic acid $C_{16}H_{24}O_4$ (175°) at 15 mm (280°). A product of the oxidation of menthol by $KMnO_4$ (Arth, *A Ch* [6] 7, 448). Colourless liquid, partially decomposed on boiling at 280°, v sl sol water, v sol alcohol and ether. The salts of alkalis and alkaline earths are very soluble. A solution of the sodium salt is ppd by salts of Pb , Fe''' , Cu , and Pt . It forms no acetyl derivative $-AgA'$ $-NaA'$ white deliquescent crystals.

Methyl ether MeA' (137°) at 17 mm. Liquid.

Ethyl ether EtA' (145°) at 18 mm. Thick liquid.

MENTHONE $C_{10}H_{18}O$ (206.3° cor) $[\alpha]_D = +21^\circ$ S.G. $\frac{4}{20}$ 9126, $\frac{4}{20}$ 8972 C.E. (0°-10°) 000862, (0°-100°) 000923 R_∞ 75.3. From menthol (30 g), $K_2Cr_2O_7$ (10 g), and H_2SO_4 (10 g) at 135°. The light oil is subjected several times to the action of the same oxidising mixture (Atkinson & Yoshida, *C J* 41, 49). Colourless oil, miscible with alcohol, chloroform, benzene, and CS_2 . Smells like diluted peppermint. Does not combine with $NaHSO_4$. If a solution in petroleum is treated with Na and CO_2 successively and then shaken with water crystals of menthol are got [42°], but having $[\alpha]_D = -39^\circ$ not -59° .

Lævo-menthone $C_{10}H_{18}O$ *tc*

$CHP < \begin{smallmatrix} CH_2 & CH_2 \\ CH_2 & CO \end{smallmatrix} > CHMe (?)$ (207°) S.G. $\frac{4}{20}$ 8960 $[\alpha]_D = -28.2^\circ$. Menthone is a mixture of two isomerides—one dextro, the other lævo-rotatory. By using very little acid the lævo-menthone may be obtained free from dextro-menthone and menthol. The best proportions are 60 g. $K_2Cr_2O_7$, 50 g. H_2SO_4 , 300 g. water, and

45 g. menthol, the mixture being kept at 80° to 55° (Beckmann, *A* 250, 325). The menthone is extracted with ether, washed with dilute alkalis, and distilled with steam.

Properties—Mobile liquid, smelling faintly of peppermint, sl sol water, miscible with alc. hohol, ether, and petroleum ether. The molecular weight determined by Raoult's method agrees with the formula. The molecular re-

fraction $\frac{(n^2-1)P}{(n^2+2)d}$ is 46.3. Lævo menthone is

converted into a mixture of dextro and lævo menthone by acids, bases, water, heat, or even on keeping.

Oxim $C_{10}H_{17}NOH$. Mol w 169 [58°]. $[\alpha]_D = -42.5^\circ$. Crystalline, sol dilute alcohol, ether, and petroleum ether. Raoult's method gives, when acetic acid is used, the mol w 169, but when benzene is used it gives 251. With HCl the oxim forms a compound $(C_{10}H_{17}NOH)HCl$ [119°], a white crystalline powder $\rightarrow C_{10}H_{15}NONa$.

Dextro menthone $C_{10}H_{18}O$. Mol w 154 (208°) S.G. $\frac{20}{20}$ 900 $[\alpha]_D = +28.14^\circ$. Obtained by freezing a mixture of H_2SO_4 (10 pts) and water (1 pt), adding menthene (2 pts), and shaking. The temperature is slowly raised to 30°, the product poured into ice, and the menthone extracted by ether (Beckmann, *A* 250, 334). Colourless mobile oil, sl sol water, miscible with alcohol, ether, and petroleum ether. The mol w determined by Raoult's method is 150. The action of acids, bases, water, heat, and time convert dextro menthone into a mixture of dextro and lævo menthone.

Oxim $C_{10}H_{17}NOH$. Thick oil, slightly lævo rotatory. The mol w determined by Raoult's method is 165 when acetic acid is used, and 228 when benzene is employed as solvent $-(C_{10}H_{17}NOH)HCl$ [c 97°] Deliquescent $\rightarrow C_{10}H_{15}NONa$.

MENYANTHIN $C_{20}H_{32}O_{11}$ [60°-115°]. A bitter glucoside found in buckbean (*menyanthes trifoliata*) (Brandes, Kromayer, *Ar Ph* [2] 108, 257, 124, 37, *Fr* 1, 15). Prepared by treating the aqueous extract with animal charcoal at 65°, and subsequently extracting the charcoal with alcohol. Amorphous yellowish mass, sl sol cold water, v sol hot water and alcohol, insol ether. Dissolves in aqueous alkalis. Its solutions are not ppd by metallic salts. It is ppd by tannin. When distilled with dilute H_2SO_4 it gives off volatile menyanthol, while glucose $C_6H_{12}O_6$ aq remains behind.

Menyanthol $C_8H_{16}O$ is an oil smelling like benzoic aldehyde. It reduces ammoniacal $AgNO_3$. By exposure to the air, or by potash-fusion, it is converted into a crystalline sublimable acid.

Menyanthin. This name has also been applied to inulin when prepared from buckbean.

MERCAPTALS. Compounds of the form $RCH(SR_2)$. They may be viewed as thio acetals or as the sulphur compounds corresponding to the alkyl derivatives of ortho aldehydes. **V. THIO ALDEHYDES**

MERCAPTAN C_2H_5S *tc* C_2H_5SH *Ethyl mercaptan Thio alcohol*. Mol w 62 (36.5°). S.G. $\frac{4}{20}$ 8891 V.D. 2.11 (calc 2.15). S.V. 76 (Loosen, *A*, 264, 71) H.F.p. 14,480. H.F.v.

18,271 (Thomsen) R_{∞} 18 62 (Nasini, *G* 18, 301)

Formation—1 By distilling calcium ethyl sulphate $\text{CaEt}_2(\text{SO}_4)_2$ with a solution of barium sulphhydrate (Zeise, *P* 31, 369)—2 A mixture of alcohol and H_2SO_4 is neutralised with KOH, decanted from $\text{ppd K}_2\text{SO}_4$, mixed with excess of KOH, saturated with H_2S , and distilled (Wohler)—3 A solution of KOH (*S* G 13) is saturated with H_2S , mixed with an equal volume of a conc solution of K_2SO_4 , and distilled from a water bath (Liebig, *A* 11, 14, 23, 34) The product is freed from Et_2S by fractional distillation (Claesson, *J pr* [2] 15, 193)—4 From KSH and EtCl (Regnault, *A Ch* [2] 71, 390)—5 From KSH and EtI (Baudrimont, *C R* 51, 616)—6 By reducing with HI at 160° the solid thio aldehyde obtained by passing H_2S into a mixture of aldehyde solution and iodine (Bottinger, *B* 11, 2203)—7 Together with HETSO_4 and ether, by heating alcohol saturated with SO_2 in sealed tubes (Endemann, *A* 140, 336, Pagliani, *B* 11, 155)

Preparation—A cold mixture of alcohol (1 litre) and H_2SO_4 (500 c c) is diluted with ice and then added to a solution of crystallised sodium carbonate (4 kilos) The product is concentrated until Na_2SO_4 separates The mother liquor is further concentrated, and mixed with KOH (800 g) dissolved in water (1,500 c c) previously saturated with H_2S The whole is heated on a water bath, and the gases are passed first through a strong solution of caustic potash (50 g) and then into a solution of KOH (350 g) in water (700 g) The small amount of H_2S contained in the latter solution is ppd by lead acetate, and the mercaptan liberated by HCl It is dried with K_2CO_3 and distilled (Klason, *B* 20, 3407)

Properties—Colourless, very mobile, liquid, having a peculiarly persistent alliaceous odour V sl sol water, miscible with alcohol and ether Very inflammable, and burns with a blue flame A drop of it when briskly agitated on the end of a glass rod becomes solid, possibly through formation of a hydrate Neutral to litmus An alcoholic solution forms a yellow pp with lead salts, and white pps with cupric acetate, mercuric salts, and trichloride of gold The alcoholic solution is turned blue by FeCl_3 (Rathke, *A* 161, 148) Mercaptan is a reducing agent thus it converts nitro benzene into azo benzene Mercaptan decomposes salts of phenyl with formation of sodium phenylate and a thio ether (R Seiffert, *J pr* [2] 31, 462) But with phenyl salicylate it acts thus $\text{C}_6\text{H}_5(\text{OH})\text{CO}_2\text{Ph} + \text{NaSEt} = \text{C}_6\text{H}_5(\text{ONa})\text{CO}_2\text{Ph} + \text{HSEt}$ A trace of isatin dissolved in sulphuric acid gives, with a trace of mercaptan, a fine green colouration (Berthelot, *C R* 108, 350)

Reactions—1 Boiling nitric acid (*S* G 14) becomes red, deposits an oil, and ultimately forms ethane sulphonic acid Weaker nitric acid (*S* G 128) forms EtSO_3SEt —2 Potassium forms hydrogen and KSEt —3 P_2S_5 forms Et_2PS and Et_2HPS (Carius, *A* 112, 190)—4 Bromine forms EtBr and S_2Br_2 (Friedel & Ladenburg, *A* 145, 189)—5 Heated in sealed tubes with diazo-compounds (diazo salicylic acid diazo phenol chloride) it forms di ethyl disulphide, the diazo-compound being reduced exactly as when

boiled with alcohol (R Schmitt & O Mittenzwey, *J pr* 126, 192) $\text{C}_6\text{H}_5(\text{OH})\text{NCl} + 2\text{EtSH} = \text{Et}_2\text{S}_2 + \text{N}_2 + \text{C}_6\text{H}_5\text{OH} + \text{HCl}$ —6 PCl_5 at 100° forms thiophosphorous ether $\text{P}(\text{SEt})_3$, a fetid oil, resolved by distillation into phosphorus and Et_2S_2 —7 CCl_4 , acting on NaSEt , forms $\text{C}(\text{SEt})_4$, a light oil, *S* G 101, decomposed on distillation CCl_4 with NaSEt gives $\text{C}_2(\text{SEt})_4$, a heavy fetid oil, solidifying at very low temperatures C_2Cl_4 , heated with NaSEt at 100° gives $\text{C}_2(\text{SEt})_4$, crystallising in rhombohedra [54°]—8 S_2Cl_2 forms HCl and Et_2S_2 , which is resolved by distillation into Et_2S_2 and S_2 —9 TiCl_4 gives EtSHTiCl_3 and $(\text{EtSH})_2\text{TiCl}_2$ (Demarçay, *Bl* [2] 20, 132)—10 Reacts with ketones forming 'mercaptates' or thioketates Thus HCl passed into a mixture of acetone and mercaptan forms $(\text{CH}_3)_2\text{C}(\text{SEt})_2$ (Baumann, *B* 18, 887)—11 Mercaptan suspended in ice water and mixed with diazobenzene sulphonic acid and soda gives explosive yellow needles of $\text{SO}_3\text{Na C}_6\text{H}_4\text{N}_2\text{SEt}$ When the alcoholic solution of this salt is boiled $\text{SO}_3\text{Na C}_6\text{H}_4\text{N}_2\text{SEt}$ and nitrogen are formed (Stadler, *B* 17, 2075)

Salts—All metallic mercaptides are decomposed by HCl —* KSEt From mercaptan and K Dull white granular mass, v sol water, sl sol alcohol Its aqueous solution gives a yellow pp with lead salts— NaSEt From mercaptan and Na or NaOEt Crystalline mass, v sol water and alcohol Its aqueous solution is alkaline in reaction, and gives off all its mercaptan on boiling In dry air it oxidises to $\text{C}_2\text{H}_5\text{SO}_2\text{Na}$ When oxygen is passed through its alcoholic solution Et_2S is formed— $\text{Zn}(\text{SEt})_2$ white, indistinctly crystalline pp obtained by adding mercaptan to aqueous zinc acetate Sol NH_4Ac and leppd on neutralisation— $\text{Cd}(\text{SEt})_2$ — $\text{Co}(\text{SEt})_2$ gummy pp Unlike the other mercaptides it is not attacked by fuming HNO_3 — $\text{Ni}(\text{SEt})_2$ chocolate brown powder, not decomposed by water—* $\text{Fe}(\text{SEt})_2$ from FeCl_3 , mercaptan, and ammonia Black slimy mass, resolved by heating into mercaptan and ferrous hydrate— $\text{EtSFe}(\text{NO})$, [78°] From $\text{KSEt}(\text{NO})$, and EtI (Pavel, *B* 15, 2607)— TiSEt yellow curdy pp , sl sol water— $\text{Cu}(\text{SEt})_2$ Obtained by adding mercaptan to a solution of CuSO_4 mixed with NaOAc Pale yellow amorphous powder (Klason, *B* 20, 3407)— $\text{Hg}(\text{SEt})_2$ [77°] S 7 in 85 p c alcohol Formed on shaking HgO with mercaptan or with an alcoholic solution of mercaptan, the action being attended with great evolution of heat It is from this body that mercaptan derives its name (*corpus mercurio aptum*) White unctuous scales When its alcoholic solution is heated to 190° it is decomposed into mercury and Et_2S (Otto, *B* 18, 1289, 15, 125) The same decomposition appears to occur when it is heated in the dry state It is not decomposed by aqueous KOH, but aqueous K_2S forms some HgS and KSEt H_2S forms HgS and mercaptan Nitric acid oxidises it to $(\text{C}_2\text{H}_5\text{SO}_3)_2\text{HgHgO}$ When melted with lead the products are mercury, PbS , and Et_2S Mercury mercaptide forms with iodoform needles of $(\text{EtS})\text{Hg}(\text{CHI}_3)$ [85.5°] (Jackson & Oppenheim, *B* 8, 1033)— EtSgHgCl White bulky pp obtained on mixing an alcoholic solution of mercaptan with HgCl_2 Changes after some time to crystalline laminae Sl sol. water and ether,

m sol boiling alcohol (Debus, *A* 72, 18) — $\text{Pb}(\text{SEt})_2$. Yellow pp, got by mixing alcoholic solutions of lead acetate and mercaptan. Decomposed by heating with alcohol at 190° into PbS and Et_2S — $\text{Bi}(\text{SEt})_3$, [79°] Obtained by mixing a solution of a salt of bismuth with mercaptan. Long flexible yellow needles, m sol alcohol and ether. Oxidises in the air. Resolved by heat into BiS and Et_2S — $\text{Sn}(\text{SEt})_4$. Formed by mixing solutions of mercaptan and SnCl_4 in CS_2 , and evaporating the solvent. Also from mercaptan and a conc aqueous solution of SnCl_4 . Oil, remaining liquid at -40° . May be distilled *in vacuo*, but when heated under atmospheric pressure it decomposes yielding Et_2S and metallic tin — $\text{Sn}(\text{SEt})_2$, yellow pp which quickly oxidises in air — EtSSbCl_4 . Oil, formed by evaporating a mixture of mercaptan and SbCl_5 . Decomposed by water with liberation of mercaptan — $\text{As}(\text{SEt})_3$. Obtained by adding NaSEt to an ethereal solution of AsCl_3 . Oil, with unpleasant odour. Decomposed on distillation into arsenic and Et_2S — $\text{ClAs}(\text{SEt})_2$. From AsCl_3 and mercaptan in the cold — EtSAu . White gelatinous pp obtained on mixing dilute alcoholic solutions of auric chloride and mercaptan — $\text{Pt}(\text{SEt})_2$, light yellow pp — $\text{Rh}_2(\text{SEt})_4$, yellow pp.

Hydrate $\text{EtSH} \cdot 18\text{H}_2\text{O}$. Solidifies as a crystalline mass when moist vapour of mercaptan is passed through a condenser cooled below 8° (H. Muller, *Ar Ph* [2] 150, 147). Mass of small needles, insol water and mercaptan. A compound containing 1.6 p.c. carbon, crystallising in prisms, is obtained by pouring mercaptan into a solution of H_2S at 0° . It perhaps contains H_2S as well as water. It melts and decomposes above 3° (Blakie, *Pr E* 10, 87).

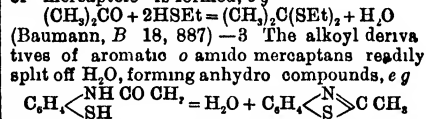

MERCAPTANS (Sulphydrates) Compounds of the formula RSH where R is a hydrocarbon radicle. They may be viewed as acid ethers of sulphydric acid or as alcohols in which O has been displaced by S . Just as H_2S is more acid than H_2O , the mercaptans are more acid than the alcohols. Thus they readily form salts by reacting with metallic oxides, and they derive their name from the ease with which they form mercuric salts. The salts of mercaptans may be called mercaptides. The mercaptans boil at a lower temperature than the corresponding alcohols, just as H_2S has a lower boiling point than H_2O . The mercaptans have an unpleasant odour. They are very readily oxidised, forming disulphides R_2S_2 , and finally sulphonic acids RSO_3H . The oxidation to sulphonic acids is best effected by nitric acid, and the chlorides of the sulphonic acids RSO_2Cl when reduced by tin and HCl yield the mercaptans again (Vogt, *A* 119, 152). By heating mercaptans with H_2SO_4 , disulphides R_2S_2 are formed (Erlenmeyer a Lisenko, *J* 1861, 590).

Preparation — 1 Fatty, but not aromatic, mercaptans are formed by heating a solution of KSH with alkyl chlorides or iodides or with potassium alkyl sulphates — 2 By heating alcohols or phenols with P_2S_5 (Kekulé, *A* 90, 311, *Z* 1867, 193). The yield is small — 3 By reducing chlorides of sulphonic acids with zinc or tin and dilute H_2SO_4 or HCl . This process is very convenient for the preparation of aromatic mercaptans. The product is distilled with steam.

4 Aromatic mercaptans may be prepared by treating diazo compounds with K_2S (Klason, *B*, 20, 350) — 5 Aromatic mercaptans may be obtained by reducing the corresponding disulphides with zinc and H_2SO_4 — 6 Aromatic mercaptans can be formed, together with the corresponding sulphides, by the action of aluminium chloride on a mixture of hydrocarbon and sulphur at 80° (Friedel a Crafts, *Bl* [2] 31, 464) — 7 When three atoms of hydrogen in the benzene nucleus have been displaced by chlorous radicles, and two of these are NO , and a halogen in ortho position to each other, alcoholic KSH displaces the halogen by SH (Beilstein a Kurbatoff, *A* 197, 75) — 8 By treating aromatic diazo compounds with sodium thiosulphate and reducing the resulting aromatic thiosulphates with zinc and H_2SO_4 (Leuckart, *G P* 1887, 45, 120).

Properties — Oils or crystalline solids with unpleasant odour. Insol water. The salts of the heavy metals are sparingly soluble in water. The mercuric salts can usually be recrystallised from alcohol. When a small quantity of a 1 p.c. solution of isatin in H_2SO_4 is mixed with a few c.c. of the strong acid and a small quantity of a fatty mercaptan, a green colouration is produced. Aldehydes and the higher alcohols interfere with the isatin reactions, and in this case the liquid may be shaken with a solution of KOH and then mixed with a little sodium nitroprusside, when a reddish violet colouration is produced (Demigès, *C R* 108, 350). The alkyl sulphides do not give this reaction. When sulphides are present they should first be pptd by an alkaline solution of PbO .

Reactions — 1 The ammoniacal solutions of aromatic mercaptans oxidise in the air with formation of disulphides — 2 When HCl is passed into a mixture of a ketone and a mercaptan condensation takes place and a thioketate or 'mercaptate' is formed, e.g.

These anhydro-compounds may even be formed by boiling the alkyl derivatives of aromatic amines with sulphur. They are also formed by the oxidation (by K_2FeCy_6) of the thioalkyl derivatives of aromatic amines. They are volatile liquids which exhibit feeble basic characters, and regenerate the amido mercaptans when fused with potash (Hofmann, *B* 13, 8, 1223, Jacob sen, *B* 19, 1069). When o-amido mercaptans are diazotised they produce characteristic stable compounds of the form $\text{C}_6\text{H}_4\text{--}\begin{array}{c} \text{N} \\ \text{S} \end{array}\text{N}$.

MERCAPTURIC ACIDS Acids obtained by placing chloro- or bromo benzene in food eaten by dogs. *V BROMO PHENYL* and *CHLORO PHENYL-MERCAPTURIC ACIDS*.

MERCURAMMONIUM COMPOUNDS (Ammonio mercury compounds Ammoniacal mercury bases Mercurammines) By the reactions of ammonia, or ammonium salts, on compounds of Hg , compounds are obtained, many of which may be represented by the empirical formulae $x\text{HgX} \cdot y\text{NH}_3$ and $x\text{HgX}_2 \cdot y\text{NH}_3$, where X = acidic radicle, some of the compounds, however, con-

tain N and H in the ratio NH_2 , and some are composed of N, Hg, and acidic radicles only. The mercurammonium compounds, as a class, do not react as loose compounds of Hg salts with NH_3 , but rather as compounds of Hg, N, H, and acidic radicles.

The mercurammonium compounds were regarded by Kane as compounds of NH_2Hg . Thus, the compound $HgONH_2$ was formulated as NH_2HgOH , and the compound $HgSO_2NH_2$ as $NH_2HgOSO_2NH_2$ (*A Ch* [2] 72, 215). Hirzel (*A* 84, 258) represented the mercurammonium compounds as compounds of mercuric nitride, N_2Hg_2 . Gerhardt suggested that these compounds are derived from NH_3 by replacing H by Hg, and after the ammonium hypothesis had been somewhat developed, Hofmann attempted to derive the compounds in question from different hypothetical mercurammoniums, i.e. compounds formed by replacing the H of NH_3 more or less completely by Hg (*v Handwörterbuch der Chemie* [2nd ed.] 2, 751, cf. Schmieder, *J pr* 75, 147, Nessler, *J* 1856 409). On this view, the compounds $HgCl_2 \cdot 2NH_3$ and $HgSO_4 \cdot 2NH_3$

are represented as $Hg \begin{smallmatrix} \text{NH}_2\text{Cl} \\ \text{NH}_2\text{Cl} \end{smallmatrix}$ and

$Hg \begin{smallmatrix} \text{NH}_2\text{SO}_4 \\ \text{NH}_2\text{SO}_4 \end{smallmatrix}$, derived from $\begin{smallmatrix} \text{NH}_2\text{Cl} \\ \text{NH}_2\text{Cl} \end{smallmatrix}$ and

$\begin{smallmatrix} \text{NH}_2\text{SO}_4 \\ \text{NH}_2\text{SO}_4 \end{smallmatrix}$. The mercurammonium compounds

may be divided, on this view, into classes according to the hypothetical Hg derivative of ammonium from which they are supposed to be derived. Thus we have the following N_2H_2Hg = mercurammonium, $N_2H_2Hg_2$ = mercurousammonium, $N_2H_2Hg_3$ = dimercurammonium, $N_2H_2Hg_4$ = dimercurousammonium, the mercurammonium compounds are those containing divalent Hg, and the compounds of monovalent Hg are called mercurousammonium derivatives. The compound $2HgONH_2$, obtained by the reaction of HgO with NH_4Aq , is represented on the ammonium hypothesis as hydrated mercurammonium hydrazide, $NH_2HgOH \cdot H_2O$.

A division is sometimes made between those mercurammonium compounds which contain N and H in the ratio NH_2 , and those which contain these elements in the ratio NH_4 , the latter are called mercuramide compounds.

Although some compounds readily give off NH_3 when heated, and others only when heated with alkali, yet it seems simpler to name all the compounds under consideration in accordance with the ammonium hypothesis. In this article the mercurammonium compounds are divided into two classes, mercurous and mercuric, the former being called mercurous and the latter mercuric compounds, the name given to each compound is intended to indicate the number of NH_2 groups from which the compound is derived, and the number of Hg atoms (mercurous or mercuric) in the formula. Several compounds are known whose reactions seem well expressed by supposing them to contain the group $HgOH$, such compounds are called mercurous ammonium derivatives in this article.

The following table presents the classification and nomenclature adopted in the present article --

Class I Mercurous compounds

Series (i) Mercurous-ammonium compounds, e.g. $(NH_2Hg)Cl$

„ (ii) Dimercurous-ammonium compounds, e.g. $(NH_2Hg_2)Cl$

Class II Mercuric compounds

Series (i) Mercuric-ammonium compounds, e.g. $(NH_2Hg)Cl$

„ (ii) Dimercuric-ammonium compounds, e.g. $(NH_2Hg_2)O$

„ (iii) Mercuric-diammonium compounds, e.g. $(N_2H_2Hg)I_2$

„ (iv) Dimercuric-diammonium compounds, e.g.

$(N_2H_2Hg_2)SO_4 \cdot H_2O$

„ (v) Trimercuric-diammonium compounds, e.g.

$(N_2H_2Hg_3)SO_4 \cdot 2H_2O$

Class III Mercurous ammonium compounds, e.g. $(NH_2Hg_2O)OH$, $(NH_2Hg_2O)SO_4$

Dimercurous ammonium chloride $(NH_2Hg_2)Cl$ is sometimes called mercurous chloramide or amido mercurous chloride, to express this view of its constitution the formula is written $Hg(NH_2)Cl$. So also mercurous ammonium chloride $(NH_2Hg)Cl$ is sometimes called ammonio mercurous chloride, and the formula is written, empirically, $HgClNH_2$, the formula of this compound is frequently doubled, and the name mercurousammonium chloride— $(N_2H_2Hg_2)Cl_2$ —is given to it. The salts called in this article mercurous ammonium compounds may be regarded as hydrated dimercurous ammonium salts, thus, the chloride $(NH_2Hg_2O)Cl$ may be written $(NH_2Hg_2O)Cl \cdot H_2O$, and the carbonate $(NH_2Hg_2O)_2CO$, may be written $(NH_2Hg_2O)_2CO \cdot 2H_2O$.

Class I Mercurous compounds $NH_2 \cdot 2Hg \cdot X$

The experiments of Barfoed (*J pr* [2] 39, 201) make it probable that the so called mercurous ammonium compounds are really mixtures of mercuric compounds and Hg. B asserts that exactly half the Hg in the black pps formed by NH_4Aq in solutions of mercurous salts exists uncombined, that nearly the whole of this Hg disappears as vapour when the pps are freely exposed to air, and that the light coloured compounds remaining are the same as those produced by adding NH_4Aq to mercuric salts. To the pp produced from $HgNO_3$, Barfoed gives the composition $3Hg + 2(HgNH_2NO_3)HgO$, that produced from Hg_2SO_4 is $4Hg + (NH_2Hg_2)SO_4 \cdot 2HgO$, that from $HgCl$ is $Hg + NH_2Hg_2Cl$, and that from $Hg_2C_2O_4$ is $4Hg + (NH_2Hg_2)_2C_2O_4 \cdot 2HgO$.

Series (i) Mercurous ammonium compounds; NH_2HgX

Mercurous-ammonium chloride, $(NH_2Hg)Cl$. (*Ammonio mercurous chloride* ($HgClNH_2$), *Mercurous ammonium chloride* ($N_2H_2Hg_2Cl_2$)). A black powder, obtained by saturating $HgCl$, prepared by ppn, with NH_3 gas, on gently warming all NH_3 is given off (*H Rose*, P 20, 159). The dissociation of this compound has been studied by Isambert (*C R* 66, 1259, v *Disso* *ciation*, vol II p 397). According to Barfoed (*J pr* [2] 39, 201) the compound formulated as above is really a mixture of Hg, mercuric ammonium chloride (NH_2Hg_2Cl) , and NH_4Cl .

Series (ii) Dimercurous-ammonium compounds, NH_2Hg_2X

Dimercur ammonium chloride, $(\text{NH}_4\text{Hg})\text{Cl}$ (*Mercurchloramide* or *amido-mercurous chloride* (HgNH_2Cl) *Tetramercurio - diammonium chloride* $(\text{N}_2\text{H}_4\text{Hg}_2\text{Cl}_2)$) A black solid, obtained by digesting HgCl with NH_4Aq ($2\text{HgCl} + 2\text{NH}_4\text{Aq} = \text{NH}_4\text{Hg}_2\text{Cl} + \text{NH}_4\text{ClAq}$) Becomes dark grey when dried, heated, gives off NH_3 and N , and at a higher temperature yields a sublimate of HgCl and Hg , treated with HCl gas, gives HgCl and NH_4Cl (Kane, *A Ch* [2] 72, 215, Ullgren, *P* 42, 395) According to Barfoed (*J pr* [2] 39, 201) the black solid obtained as described is a mixture of Hg and NH_4HgCl

Mercur ammonium nitrates Various compounds of the form $x\text{Hg}_2\text{O} \cdot y\text{N}_2\text{O}_5 \cdot z\text{NH}_3$ have been described by Kane (*lc*) and Mitscherlich (*P* 9, 387, 16, 41), but Barfoed's experiments make it very probable that these bodies are mixtures of Hg and mercuri ammonium salts (*vsupra*)

Class II. MERCURIC COMPOUNDS $\text{N}_2\text{H}_4 \cdot \text{Hg}_2\text{X}_2$

Series (1) Mercuri ammonium compounds, NH_4HgX Obtained by interaction of excess of NH_4Aq with mercuric salts in solution

Mercuri-ammonium chloride, $(\text{NH}_4\text{Hg})\text{Cl}$ (*Mercuri-chloramide*, or *amido mercuric chloride* (HgNH_2Cl) *Dimercuri diammonium chloride* $(\text{N}_2\text{H}_4\text{Hg}_2\text{Cl}_2)$ *Infusible white precipitate*) According to Rammelsberg (*J pr* [2] 38, 558) this salt is a double compound of dimercuri ammonium chloride— NH_4HgCl —and NH_4Cl , R assigns to it the formula $\text{NH}_4\text{HgCl} \cdot \text{NH}_4\text{Cl}$ (*vsupra*)

When excess of NH_4Aq is added to HgCl_2Aq , or when HgCl_2Aq is dropped into NH_4Aq , a white pp is obtained, this pp was long considered identical with that obtained by adding $\text{Na}_2\text{CO}_3\text{Aq}$ to HgCl_2Aq mixed with NH_4ClAq , and known in pharmacy as *Mercurius precipitatus albus* Wöhler (*P* 26, 203) found that the pp formed by NH_4Aq was volatilised without fusion when heated in a Pt dish, but that the pp formed by $\text{Na}_2\text{CO}_3\text{Aq}$ melted before it volatilised. The pp by NH_4Aq was then called *infusible white precipitate*, and to that produced by $\text{Na}_2\text{CO}_3\text{Aq}$ the name *fusible white precipitate* was given

Preparation— HgCl_2Aq is added to excess of cold NH_4Aq , the pp is collected at once, rapidly washed with a little cold water, and dried at 110° (André, *C R* 108, 293, 290) André (*lc*) has examined the compounds obtained by the interaction of NH_4Aq with HgCl_2Aq , varying the relative masses of the reacting bodies and the time of contact Using equal volumes of HgCl_2Aq , containing 33.875 g HgCl_2 per litre, and NH_4Aq containing 4.25 g NH_3 per litre, the pp after drying at 110° was not quite pure NH_4HgCl , but contained a little mercurous ammonium chloride $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ The quantity of $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ increased by allowing the reacting bodies to remain in contact, and also by increasing the quantity of NH_4Aq , when the NH_3 and HgCl_2 were present in the ratio $6\text{NH}_3 \cdot \text{HgCl}_2$, the pp contained equal molecular proportions of NH_4HgCl and $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$, and by further increasing the NH_3 , only $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ was obtained André found that NH_4Cl tends to change $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ into NH_4HgCl , by adding 1 vol HgCl_2Aq to 5 vols NH_4Aq (strength as given above), decanting after 24 hours, and agitating the pp for 2 days with 2 vols NH_4ClAq (containing 13.4 g.

per litre), pure NH_4HgCl was obtained André has also examined the pps obtained by adding NH_4Aq , and also NH_4ClAq , to HgCl_2Aq in presence of KOH (*C R* 108, 1108, 1164) The pps are compounds of NH_4HgCl , $\text{NH}_4\text{Hg}_2\text{O}$, and $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ in varying proportions

Properties—A white solid, which volatilises completely, when strongly heated, without melting Readily sol in HClAq , not blackened by NH_4Aq , dissolved by acids, also by hot solutions of NH_3 salts

Reactions—1 When heated, in an open vessel, does not melt but yields a sublimate of HgCl and a mixture of 1 vol N and 2 vols NH_3 , $(6\text{NH}_4\text{HgCl} = 6\text{HgCl} + 4\text{NH}_3 + \text{N}_2)$, Kane, *A Ch* [2] 72, 215) When slowly heated in a retort to c 340° , HgCl , and NH_3 are given off, and a red crystalline compound, $2\text{NH}_4\text{HgCl} \cdot \text{HgCl}_2$, remains —2 Decomposed by water, slowly by cold, more rapidly by hot, eventually with formation of yellow mercurous ammonium chloride, $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$, and NH_4Cl ($2\text{NH}_4\text{HgCl} + \text{H}_2\text{O} + \text{Aq} = (\text{NH}_4\text{Hg}_2\text{O})\text{Cl} + \text{NH}_4\text{ClAq}$) —3 Potash or soda separates $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ and evolves NH_3 Only half the N of the original NH_4HgCl is evolved as NH_3 (Kane, *lc*), but by boiling for some days with KOH , renewed from time to time, all the N is removed as NH_3 , and HgO remains (Schmieder, *J pr* 75, 147) The fact that only half the N is readily evolved as NH_3 , by the action of alkalis on NH_4HgCl , has induced Rammelsberg (*J pr* [2] 38, 558) to regard this body as a compound of dimercuri ammonium chloride and NH_4Cl , and to give it the formula $\text{NH}_4\text{HgCl} \cdot \text{NH}_4\text{Cl}$ But it is to be remembered, as pointed out by Kane, that water readily separates NH_4HgCl into $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ and NH_4Cl , hence the NH_3 obtained by the action of aqueous alkali is probably due to the direct decomposition of NH_4Cl by the alkali —4 Boiled with very dilute sulphuric acid till dissolved, the compound $\text{HgCl}_2 \cdot 2\text{NH}_4\text{Cl} \cdot 2\text{H}_2\text{SO}_4$ forms on cooling (Kosman, *A Ch* [3] 27, 238) —5 Heated in dry hydrogen chloride, HgCl_2 and NH_4Cl are produced (Ullgren, *A* 26, 203) —6 Heated with solutions of sodium chloride potassium iodide, barium sulphide, &c, NH_3 is evolved and HgCl_2 , HgI_2 , HgS , &c, formed, e.g. $\text{NH}_4\text{HgCl} + 2\text{KI} + \text{H}_2\text{O} = \text{HgI}_2 + \text{KClAq} + \text{KOH} + \text{NH}_3$ (Kane, *lc*, Rammelsberg, *P* 48, 182) —7 Boiled with ammonium chloride solution, mercuri diammonium chloride $\text{N}_2\text{H}_4\text{Hg}_2\text{Cl}_2$ (*fusible white precipitate*) is produced —8 Decomposed by heating with sulphur, with formation of a yellow sublimate of a chlorosulphide of N —9 Rubbed with iodine and a little alcohol, HgI_2 is formed and then an explosion occurs, probably from production and decomposition of N iodide (Rice, *Ph* [3] 6, 765, cf. Schwarzenbach, *B* 8, 1231, Flückiger, *B* 8, 619) —10 Bromine and chlorine cause evolution of N and formation of HgBr_2 , or HgCl_2 (Schwarzenbach, *B* 8, 1231) —11 Decomposed by alcoholic iodides, e.g. EtI (*v* Sonnenschein, *A* 101, 20) —12 For reaction with amylic mercaptan *v* Wagner, *J pr* 53, 378

Combinations—1 Forms various compounds with NH_4HgCl and $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$; obtained by adding NH_4Aq or NH_4ClAq to solutions of HgCl_2Aq containing KOH (André, *C R* 108, 1108, 1164) —2 Combines with HgCl_2 to form

NH_4HgCl HgCl_2 ; produced by slowly heating to $c\ 340^\circ$ in a retort (Millon, *A Ch* [3] 18, 392)

Mercuri-ammonium bromide, $(\text{NH}_4\text{Hg})\text{Br}$ (*Mercuri bromide*, or *amido-mercuric bromide* ($\text{Hg NH}_2\text{Br}$)) *Dimercuri diammonium bromide* ($\text{N}_2\text{H}_4\text{Hg}_2\text{Br}_2$)) A yellow powder, obtained by ppg HgBr_2Aq with excess of NH_4Aq (*cf Mercuri ammonium chloride, supra*). Insol water or alcohol, slowly changed by cold water, more quickly by hot water, to NH_2HgBr (Pesci, *G* 19, 509) E sol NH_4Aq Heated gives N , NH_3 , and HgBr , when very slowly heated to $c\ 340^\circ$ gives NH_3 , HgBr , NH_3 , and NH_2HgBr (Mitscherlich, *J pr* 19, 455)

Series (ii) Dimercuri ammonium compounds, NH_2X According to Pesci (*G* 19, 509) many and probably all the dimercuri ammonium salts, when digested with NH_4Cl , NH_4Br , or NH_4I solution, evolve NH_3 in the proportion of 4NH_3 for each NH_2 group in the dimercuri-ammonium salt This reaction may be applied to estimate dimercuri ammonium salts, by conducting the digestion in a closed vessel containing a dish with a measured quantity of normal oxalic acid

Dimercuri-ammonium hydroxide, NH_2OH (*Mercurammonium hydroxide*) Prepared by saturating yellow HgO with NH_3 under increased pressure, finely powdering, and again saturating with NH_3 , or by shaking HgO with alcoholic NH_3 for some hours and drying at ordinary temp in NH_3 gas, the product, which is $\text{NH}_2\text{OH} \cdot \text{H}_2\text{O}$, is then heated in dry NH_3 to $80^\circ\text{--}85^\circ$ The operation should be conducted in the dark (Weyl, *P* 121, 601, 131, 539) A brown powder, explodes when strongly heated, decomposed by water, with evolution of NH_3 , absorbs CO from air, evolving NH_3 at the same time, dissolves in warm HClAq or HNO_3Aq with formation of salts of Hg and NH_4

Heated to 100° in absence of air, gives *dimercuri ammonium oxide* $(\text{NH}_2)_2\text{O}$ A dark brown powder which explodes when heated, struck, or rubbed in a mortar, readily combines with water to form $\text{NH}_2\text{OH} \cdot \text{H}_2\text{O}$, soluble in HClAq and HNO_3Aq , reacts with HCl gas to form HgCl_2 and NH_4Cl This oxide is also formed by the action of liquid NH_3 on HgO

The hydrate of dimercuri-ammonium hydroxide $\text{NH}_2\text{OH} \cdot \text{H}_2\text{O}$, is a yellow powder, obtained as described above It appears to be isomeric with mercurous ammonium hydroxide $(\text{NH}_4\text{Hg}_2\text{O})\text{OH}$ (p 211)

Dimercuri-ammonium chloride, NH_2Cl (*Mercurammonium chloride*) Obtained by treating the hydroxide (*v supra*) with alcoholic solution of HCl , also by treating the oxychloride formed by fusing together HgO and HgCl_2 in the ratio $3\text{HgO} \cdot \text{HgCl}_2$ with liquid NH_3 , and removing excess of NH_3 by warming in a stream of dry air at 150° Forms a yellow powder, decomposed suddenly at 300° to HgCl_2 , Hg , and N (Weyl, *P* 121, 601, 131, 529). Not acted on by boiling water, decomposed by hot KOH Aq with production of NH_3 and HgO ; slowly dissolved by cold HClAq

Forms a double compound with mercuric chloride $2\text{NH}_2\text{Cl} \cdot \text{HgCl}_2$ (*dimercuri-ammonium-mercuric chloride*). A red crystalline solid, resembling HgO , produced by very slowly

heating mercuri ammonium chloride, $\text{NH}_4\text{Hg Cl}$, in a retort until HgCl begins to sublime This compound reacts with hot HClAq to form NH_4Cl and HgCl_2 , it is said to be unchanged by conc HNO_3Aq , dilute $\text{H}_2\text{SO}_4\text{Aq}$, H_2O , or boiling alkali solutions (Mitscherlich, *J pr* 19, 453) Heated to 360° it separates into N , HgCl , and Hg

Dimercuri-ammonium bromide, NH_2Br (*Mercurammonium bromide*) Obtained by ppg HgBr_2Aq by excess of NH_4Aq and digesting the pp (NH_4HgBr) with water, better, by adding excess of NH_3 carbonate to HgBr_2Aq , washing the pp of $4\text{NH}_4\text{Br} \cdot 5\text{NH}_3\text{Br}$ with NH_4 carbonate, warming with KOH Aq , and washing with cold water (Pesci, *G* 19, 509) Also obtained, according to Pesci, by the action of dilute HBr Aq on Millon's base $(\text{NH}_4\text{Hg}_2\text{O})\text{OH}$ A yellow powder, insol water, sol HClAq , insol HNO_3Aq , decomposed by heat, without melting, yielding NH_3 and a sublimate which contains Hg (Pesci, *lc*) Digested for a short time with boiling $\text{NH}_4\text{Br Aq}$, and filtered, small crystals of $\text{NH}_4\text{Br} \cdot 5\text{NH}_3\text{Br}$ are obtained This compound seems similar to *fusible white precipitate*, it is described on p 210 as *mercuri diammonium bromide* The double compound $4\text{NH}_2\text{Br} \cdot 5\text{NH}_3\text{Br}$ is obtained, in clear microscopic needles, by adding excess of NH_3 carbonate to HgBr_2Aq (Pesci, *lc*)

Dimercuri ammonium iodide, NH_2I , is obtained by the action of liquid NH_3 on the oxy iodide formed by fusing together HgO and HgI_2 in the ratio $3\text{HgO} \cdot \text{HgI}_2$ (Weyl, *P* 121, 601, 131, 539)

Dimercuri ammonium selenate, $(\text{NH}_2)_2\text{SeO}_4 \cdot 2\text{H}_2\text{O}$ A white pp which darkens in light and is decomposed by heat; obtained by dissolving the basic selenate $\text{HgSeO}_4 \cdot 2\text{HgO}$ in conc NH_3Aq , and ppg by much water (Cameron a Davy, *C N* 44, 63)

Series (iii) Mercuri diammonium compounds, $\text{N}_2\text{H}_4\text{HgX}_2$

Mercuri-diammonium chloride, $\text{N}_2\text{H}_4\text{Hg Cl}_2$ (*Mercurammonium chloride*) *Fusible white precipitate* *Ammonio mercuric chloride*, $\text{HgCl}_2 \cdot 2\text{NH}_3$ Rammelsberg (*J pr* [2] 38, 558) regards this salt as a double compound of dimercuri ammonium chloride— NH_2Cl —and NH_4Cl He formulates it as $\text{NH}_2\text{Cl} \cdot 3\text{NH}_4\text{Cl}$ (*v infra*)

When an alkali carbonate is added to HgCl_2Aq containing NH_4Cl , a white pp is obtained, this pp was called in pharmacy *mercurius precipitatus albus*, and for long was supposed to be the same as that formed by adding NH_4Aq to HgCl_2Aq Wöhler (*P* 26, 203) found that the pp formed by alkali carbonate, in presence of sal ammoniac, melted when heated, before volatilising, but that the pp formed by ammonia volatilised without melting The former pp was then called *fusible white precipitate*, to distinguish it from the latter to which the name *infusible white precipitate* was given

The researches of Krug (*Ar Ph* 42, 1) have shown that pure mercuri diammonium chloride cannot be obtained by addition of alkali carbonate to HgCl_2Aq containing NH_4Cl at the ordinary temperature, the pp consists of a mixture of mercuri ammonium chloride (*infusible white precipitate*, $\text{NH}_2\text{Hg Cl}$) and mercuri-diam-

monium chloride (*fusible white precipitate*, $N_2H_5HgCl_2$), the longer the pp remains in contact with the supernatant liquor, and the higher the temperature, the greater is the amount of *fusible white precipitate* formed. Krug found that almost pure NH_4HgCl (*infusible white precipitate*) was obtained by adding Na_2CO_3 to $HgCl_2$ mixed with NH_4Cl at 0° , and filtering at once (about $4Na_2CO_3$, $3HgCl_2$, $9NH_4Cl$). The first pp formed by the alkali carbonate therefore probably always consists mostly of mercuri ammonium chloride, NH_4HgCl , but this is acted on by the NH_4Cl present, and thus more or less $N_2H_5HgCl_2$ is produced, CO_2 is also given off from the alkali carbonate used, and this CO_2 , according to Krug's experiments, seems to change some of the NH_4HgCl to $HgCl_2 \cdot 2HgO$ (with simultaneous formation of NH_4Cl and NH_4HCO_3), which oxychloride then probably reacts with NH_4Cl to produce $N_2H_5HgCl_2$.

Preparation— $HgCl_2$ is dropped into boiling NH_4Cl containing NH_3 , as long as the pp which forms is redissolved, and the liquid is allowed to cool. The compound crystallises out in garnet red dodecahedra. Melts at $c 300^\circ$ with decomposition.

Properties and Reactions—Small red dodecahedra, also formed by ppn with Na_2CO_3 as a white powder. Gently heated, gives off half its NH_3 , leaving $HgCl_2$, (*v infra*), melts at $c 300^\circ$, evolving N and NH_3 and yielding a sublimate which reacts with water to form NH_4Cl , $HgCl_2$, and $HgCl$. Boiling water reacts to form mercurous ammonium chloride, $(NH_2HgO)Cl$, and NH_4Cl . Alkalis evolve NH_3 . According to Rammelsberg (*J pr* [2] 38, 558) three fourths of the N of mercuri ammonium chloride is evolved by the action of hot alkali solution, hence B. assigns to this compound the formula $NH_4HgCl \cdot 3NH_4Cl$, but as the action of boiling water on $N_2H_5HgCl_2$ is to produce $(NH_2HgO)Cl$ and NH_4Cl in the ratio $(NH_2HgO)Cl : 3NH_4Cl$, it is easy to account for the action of boiling alkali without supposing fusible white precipitate to be a double compound of NH_4HgCl with NH_4Cl . Iodine reacts energetically, according to Fluckiger (*B* 8, 1619) the reaction is expressed thus $6(N_2H_5HgCl_2) + 2I_2 = N_2 + 6NH_4Cl + 4NH_3 + 2HgCl_2 + 2HgI_2 + 2HgCl$. Liquid ammonia dissolves $N_2H_5HgCl_2$, after prolonged action, and evaporation of the excess of NH_3 , a white crystalline mass remains which has the same composition as the original, according to Weyl (*P* 1, 547).

Combination—The compound $HgCl_2 \cdot NH_3$ may be regarded as a compound of $N_2H_5HgCl_2$ with $HgCl_2$ [N_2H_5HgCl , $HgCl_2 = 2(HgCl_2 \cdot NH_3)$]. This compound is formed by heating $HgCl_2$ in dry NH_3 , or by distilling HgO with NH_4Cl , it melts when heated and distils without much change, it is decomposed by water, forming NH_4HgCl and $HgCl_2 \cdot NH_4Cl$ (Kane, *A Ch* [2] 72, 215).

Mercuri-diammonium bromide, N_2H_5HgBr , Small microscopic, rhombohedral, transparent crystals, obtained by adding excess of NH_3 carbonate to $HgBr_2$, boiling the pp of $4NH_3$, Br 5 NH_3 , Br for a short time with NH_4Br , filtering, and allowing to cool (Pesci, *G* 19, 509). Also formed by treating dimercuri ammonium bromide (NH_4HgBr) with boiling NH_4Br , by

the action of NH_3 on solution $HgBr_2$, NH_3 , Br ; also by adding alcoholic NH_3 to $HgBr_2$ dissolved in alcohol (*P*, *lc*). Melts at $c 180^\circ$ with evolution of NH_3 , more strongly heated, yields two distinct sublimates. Easily sol. HCl and H_2SO_4 forms $HgBr_2$, alkalis produce NH_4Br (*P*, *lc*). Forms a compound with $HgBr_2$, viz. $N_2H_5HgBr \cdot HgBr_2 = (HgBr_2 \cdot NH_3)$, similar to the chloro compound already described (*H Rose*, *P* 20, 160).

Mercuri-diammonium sulphate, $N_2H_5HgSO_4 \cdot H_2O$. Lustrous, orthorhombic, crystals. Obtained by adding, little by little, yellow HgO to pure, saturated, cold $(NH_4)_2SO_4$, each portion of HgO being allowed to dissolve before another portion is added, the liquid being kept cold, addition of HgO is continued till the liquid begins to grow turbid, the clear liquid is decanted and allowed to evaporate in the air or *in vacuo*. This compound is decomposed by the smallest quantity of water with production of a compound of mercurous ammonium sulphate and mercuri ammonium sulphate,

boiling water removes more H_2SO_4 , finally forming $(NH_2HgO)_2SO_4$ (*v Mercurous ammonium sulphate*, p 211, *cf* Millon, *A Ch* [3] 18, 410, Schmieder, *J pr* 75, 147). It is soluble in $(NH_4)_2SO_4$, NH_4Cl , HCl , dilute H_2SO_4 , and HNO_3 , insol. conc. HNO_3 . Boiled with conc. H_2SO_4 , it gives $(NH_4)_2SO_4$ and $HgSO_4$, decomposed by KOH , forming a basic compound, with boiling conc. KOH , NH_3 is evolved and HgO formed. Heated to 115° water is evolved, and at a higher temperature complete decomposition results.

Mercuri-diammonium iodide, N_2H_5HgI , *Mercuri-diammonium fluoride*, N_2H_5HgF , and the double compound $N_2H_5HgI \cdot HgI_2$, have been described (*H Rose*, *P* 20, 160, Nessler, *C C* 1856 530, Finkener, *P* 110, 147, Rammelsberg, *P* 48, 170, Caillot & Carriol, *J. Ph* 9, 381).

Series (iv) Dimercuri-diammonium compounds, $N_2H_5Hg_2X_2$.

Dimercuri-diammonium sulphate, $N_2H_5Hg_2SO_4 \cdot H_2O (= SO_4 \cdot 2HgO \cdot 2NH_3)$. Obtained, according to Millon (*A Ch* [3] 18, 410), by saturating 70 cc cold conc. NH_4 with $HgSO_4$, allowing to stand in an atmosphere of NH_3 over CaO for some months, powdering the crystals which separate, and drying over CaO .

Series (v) Trimercuri-diammonium compounds, $N_2H_5Hg_3X_2$.

Trimercuri-diammonium sulphate, $N_2H_5Hg_3SO_4 \cdot 2H_2O (= SO_4 \cdot 3HgO \cdot 2NH_3)$. Prepared similarly to preceding salt, but using 90 cc NH_4 (Millon, *lc*).

Class III MERCUROXY AMMONIUM COMPOUNDS (NH_2HgO)X.

The name *mercurous* is here given to the group HgO , which is supposed to act as a dyad radicle in these compounds. The salts of this series may be regarded as *hydrated tetramercuri-diammonium compounds*, thus the carbonate $(NH_2HgO)_2CO$ may be written $N_2Hg_4O_4 \cdot CO_2 \cdot 2H_2O$, and the chloride $(NH_2HgO)Cl$ may be written $N_2Hg_4O_4 \cdot Cl_2$. Some of the salts of this series may also be regarded as hydrated *dimercuri-*

ammonium compounds, thus the chloride ($\text{NH}_2\text{Hg}_2\text{O}$)Cl loses water at 200° , and is therefore regarded by Rammelsberg as $\text{NH}_2\text{Hg}_2\text{O}$.

Mercurioxy-ammonium hydroxide, ($\text{NH}_2\text{Hg}_2\text{O}$)OH (*Millon's base*). This is the final product of the reaction of NH_4Aq on HgO , the hydroxide contains H_2O . Millon gave the formula $\text{NH}_2\text{Hg}_2\text{O} \cdot \text{OH} \cdot \text{H}_2\text{O}$, Gerresheim, the formula $2(\text{NH}_2\text{Hg}_2\text{O} \cdot \text{OH}) \cdot \text{H}_2\text{O}$ (*A* 195, 373), and Rammelsberg, more recently (*J pr* [3] 38, 558), assigns the composition $3(\text{NH}_2\text{Hg}_2\text{O} \cdot \text{OH}) \cdot 2\text{H}_2\text{O}$. The empirical formula for the base is $2\text{HgO} \cdot \text{NH}_2 \cdot \text{H}_2\text{O}$.

Preparation—Yellow HgO is agitated with NH_4Aq , quite free from carbonate, so long as any change occurs, if red HgO is used the change is not completed for some days. The yellow brown product is washed with cold water, crystallised from hot water, and dried (*Millon, A Ch* [3] 18, 392).

Properties—Yellow, microscopic crystals, probably rhombic. Appears to be isomeric with hydrated dimercuri ammonium hydroxide $\text{NH}_2\text{Hg}_2\text{OH} \cdot \text{H}_2\text{O}$ (*p* 209). Insol alcohol or ether, somewhat sol water. *S* 007 at 17° , 06 at 80° . Acts as a very strong base, decomposes NH_4 salts energetically with evolution of NH_3 , and rapidly combines with CO_2 when exposed to air. Several salts may be obtained by dissolving the base in excess of acetic acid, and ppg by alkali permanganate, chromate, &c. Over H_2SO_4 loses H_2O and becomes brown, heated to 130° further loses $\frac{1}{2}\text{H}_2\text{O}$, leaving *mercurioxy ammonium oxide* ($\text{NH}_2\text{Hg}_2\text{O}$).

Reactions—1 The hydroxide base is very slowly decomposed by boiling *alkali* solution, the dehydrated base is only decomposed by molten alkali—2 Decomposes *ammonium salts* rapidly, with evolution of NH_3 —3 Combines so rapidly with *carbon dioxide* that it is almost impossible to obtain the base quite free from carbonate—4 With acids forms salts ($\text{NH}_2\text{Hg}_2\text{O}$)X (X = NO_3 , $\frac{1}{2}\text{SO}_4$, &c) (*v* Rammelsberg, *J pr* [2] 38, 558)—5 Decomposed by *heat* with more or less explosion (*Millon, l c*, *cf* *Hirzel, J* 1852 419, 1853 381)—6 Many salts, *e.g.* sulphates and chlorides, are decomposed by shaking with *Millon's base*, with complete removal of the acid of the salt used (*v* Gerresheim, *A* 195, 873)—7 Heated with *ethylic iodide* to 100° yields crystals of $2\text{NEtI} \cdot 3\text{HgI}_2$, ethylic bromide reacts similarly—8 A thio carbonate of the base is obtained by heating with *carbon disulphide* (*Gerresheim, l c*).

Mercurioxy ammonium chloride, ($\text{NH}_2\text{Hg}_2\text{O}$)Cl (*Hydrated tetramercurammonium chloride* $\text{N}_2\text{Hg}_4\text{Cl}_2 \cdot 2\text{H}_2\text{O}$ *Hydrated dimercuri ammonium chloride* $\text{NH}_2\text{Hg}_2\text{Cl} \cdot \text{H}_2\text{O}$). This compound is formed by the reaction of boiling water with either fusible white pp $\text{N}_2\text{H}_4\text{HgCl}_2$, or infusible white pp NH_2HgCl . It is also produced by passing dry NH_3 over the oxychloride $8\text{HgO} \cdot \text{HgCl}_2$ at 150° (*Ullgren, P* 42, 395). A heavy, yellow powder, *v s* sol water, *e* sol HClAq and HNO_3Aq (*Kane, P* 42, 367). Decomposed by heat, giving NH_3 , N , H_2O , HgCl , and Hg . Decomposed by excess of solutions of KCl , NaCl , and KI , with evolution of NH_3 . Loses water at 200° , and is therefore regarded by Rammelsberg as $\text{NH}_2\text{Hg}_2\text{O} \cdot \text{H}_2\text{O}$ (*J. pr.* [2] 38, 558).

Mercurioxy-ammonium chloride combines with NH_2HgCl and $\text{NH}_2\text{Hg}_2\text{Cl}$ to form various double compounds, *e.g.*

these compounds were obtained by André by ppg HgCl_2Aq with NH_4Aq , some of them requiring the presence of KOH for their production (*C R* 108, 233, 290, 1108, 1164).

Mercurioxy ammonium iodide, ($\text{NH}_2\text{Hg}_2\text{O}$)I (*Hydrated tetramercurammonium iodide* $\text{N}_2\text{Hg}_4\text{I}_2 \cdot 2\text{H}_2\text{O}$ *Hydrated dimercuri ammonium iodide* $\text{NH}_2\text{Hg}_2\text{I} \cdot \text{H}_2\text{O}$). This compound is formed by adding NH_4Aq to *Nessler's reagent* (alkaline solution of HgI_2 in KIAq), the composition of the pp thus produced is often represented as $\text{HgNH}_2\text{I} + \text{HgO}$, or as $\text{HgNH}_2\text{I} + \text{H}_2\text{O}$. The compound is best prepared by dissolving HgI_2 , 2KI in KOH Aq , adding NH_4Aq , washing thoroughly with cold water, and drying at 160° ($2\text{K} \cdot \text{HgI}_2\text{Aq} + 3\text{KOH Aq} + \text{NH}_4\text{Aq} = (\text{NH}_2\text{Hg}_2\text{O})\text{I} + 7\text{KIAq} + 2\text{H}_2\text{O}$, *v* Rammelsberg, *P* 48, 170). ($\text{NH}_2\text{Hg}_2\text{O})\text{I}$ is also formed by heating $3\text{HgO} \cdot \text{HgI}_2$ to 180° in NH_3 (*Rammelsberg*), and by boiling HgI_2 with excess of conc NH_4Aq .

Mercurioxy ammonium iodide is a brown powder with a purple red tint. Begins to give off water at 128° , heated more highly, out of contact with air, it melts to a dark brown liquid, and then decomposes violently, giving H_2O , Hg , HgI , NH_3 , and N . Sol warm KIAq , with formation of K HgI , and KOH and evolution of NH_3 . Sol warm HClAq , HgI_2 , and HgICl are deposited on cooling (*Rammelsberg*). Decomposed by hot BaSAq , with evolution of all N as NH_3 . Heated in HCl gas, gives a sublimate of HgCl_2 , NH_4Cl , NH_4I , and (NH_4) HgI_2 .

Mercurioxy ammonium nitrates. Several nitrates, and some double nitrates, of the mercurioxy ammonium compounds seem to exist.

The salt often called *Soubiran's ammoniacal salt* is probably the *normal nitrate* ($\text{NH}_2\text{Hg}_2\text{O})\text{NO}_3$ (*Soubiran, J Ph* 12, 465). This compound is obtained by ppg dilute $\text{Hg}(\text{NO}_3)_2\text{Aq}$, containing only a little free acid, with very dilute NH_4Aq , boiling with water till the pp becomes compact and curdy, washing, and drying.

The loose flocculent pp produced by adding very dilute NH_4Aq to dilute $\text{Hg}(\text{NO}_3)_2\text{Aq}$, sometimes known as *Mitscherlich's ammoniacal salt*, is probably a *double compound of mercurioxy ammonium nitrate and mercuri ammonium nitrate*, ($\text{NH}_2\text{Hg}_2\text{O})\text{NO}_3 \cdot (\text{NH}_2\text{Hg})\text{NO}_3 \cdot \text{H}_2\text{O}$.

Other compounds are obtained by boiling *Mitscherlich's salt* with excess of NH_4Aq with addition of $\text{NH}_4\text{NO}_3\text{Aq}$, and by dissolving *Soubiran's salt* in hot conc $\text{NH}_4\text{NO}_3\text{Aq}$, the salts thus formed are probably *double compounds of mercurioxy ammonium nitrate and ammonium nitrate*, but their exact composition and constitution are not yet decided (*v* *Mitscherlich, P* 9, 387, 16, 41, *Millon, A Ch* [3] 18, 392, *Kane, A Ch* [2] 72, 215, *Nessler, J* 1856 409).

Mercurioxy-ammonium sulphate, ($\text{NH}_2\text{Hg}_2\text{O})\text{SO}_4$ (*Hydrated tetramercurammonium sulphate*, $\text{N}_2\text{Hg}_4\text{SO}_4 \cdot 2\text{H}_2\text{O}$ *Hydrated dimercuri-ammonium sulphate*,

(NH_4), SO , $2\text{H}_2\text{O}$ *Ammoniacal turpethum*) Obtained by saturating conc NH_4Aq with HgSO_4 , and allowing to evaporate in air, or over H_2SO_4 , also by digesting the basic sulphate $\text{HgSO}_4 \cdot \text{HgO}$ (*mineral turpethum*) with NH_4Aq , also by digesting HgO with hot (NH_4), SO_4Aq (Millon, *A Ch* [3] 18, 392, Ullgren, *P* 42, 395, Hirzel, *J* 1852 419, 1853 381) Schmieder (*J pr* 75, 147) obtained the salt by repeatedly treating mercuri-diammonium sulphate, $\text{N}_2\text{H}_5\text{HgSO}_4 \cdot \text{H}_2\text{O}$ (*v p* 210), with boiling water, till the filtrate was free from sulphates. Forms a heavy yellow white powder, sl sol water, easily sol HClAq or HNO_3Aq . Decomposed by heat to H_2O , N , NH_3 , and Hg_2SO_4 . Treated with KOH Aq , gives NH_3 and a *basic salt* (NH_4HgO), SO_4HgO (perhaps $\text{NH}_4\text{Hg}_2\text{ONH}_2\text{Hg}_2\text{O SO}_4$), and on further treatment with KOH Aq yields NH_3 , HgO , and K_2SO_4 .

Besides the mercurous ammonium salts described above, the following have been prepared —

Mercurous ammonium bromate ($\text{NH}_4\text{Hg}_2\text{OBrO}_3$, (Rammelsberg, *P* 55, 82)

Mercurous ammonium carbonate ($\text{NH}_4\text{Hg}_2\text{OCO}_3$, (Millon, *A Ch* [3] 18, 392, Hirzel, *J* 1852 419, 1853 381)

Mercurous ammonium chromate ($\text{NH}_4\text{Hg}_2\text{OCrO}_4$, and a *double basic salt* ($\text{NH}_4\text{Hg}_2\text{OCrO}_4 \cdot 3\text{HgCrO}_4$, HgO (Hirzel, *lc*))

Acid mercurous ammonium fluoride ($\text{NH}_4\text{Hg}_2\text{OFHF}$ (Finkener, *P* 110, 632)

Mercurous ammonium - ammonium iodate ($\text{NH}_4\text{Hg}_2\text{OIO}_3 \cdot 2\text{NH}_4\text{IO}_3$, (Millon, *A Ch* [3] 18, 410)

Mercurous ammonium - mercuric phosphate ($\text{NH}_4\text{Hg}_2\text{O}$) Hg PO_4 , (Hirzel, *J* 1852 419, 1853 381)

Mercurous - ammonium - mercuric sulphite ($\text{NH}_4\text{Hg}_2\text{O}$), SO_3 , HgSO_3 , (Hirzel, *lc*)

M M P M

MERCURIALINE The volatile base obtained by distilling the seeds of *Mercurialis annua* or *M perennis* with lime and water, and formerly called 'mercurialine,' is identical with methylamine (E Schmidt, *B* 10, 2226, A 193, 73, cf Reichardt, *J pr* 104, 301)

MERCURY (*Quicksilver*) Hg At w 199.8 Mol w 199.8 [-38.5°] (Regnault, *Acad* 26, 525) [-38.85°] (Mallet, *P M* [5] 4, 145) (357.25° at 760 mm) (Regnault, *lc*), for table of B P of Hg at pressures from 123 to 798 mm *v* Ramsay & Young, *C J* 47, 656) S G $\frac{1}{4}$ 13.5958 to 13.596 (Regnault), $\frac{10}{15}$ 13.546 (Volkman, *W* 13, 209, a very full table of S G and volume of Hg from 0° to 360° is given) S G solid Hg , $^{-28.5^\circ}$ = 14.1932 (Mallet, *P M* [5] 4, 145) V D 99.3 at 440° to 1565° (V Meyer, *B* 12, 1426) S H 03312 from 20° to 50° , 03278 from 25° to 142° (Winkelmann, *P* 159, 152, *v* also Pettersson, *B* 12, 1718)

Occurrence—Small quantities of Hg are found as globules disseminated through ores of Hg , or in the rocks in which these ores occur. The chief ore of Hg is *cinnabar*, HgS , found in limited quantities in Illyria, Spain, Bohemia, Peru, China, California, the Ural, and one or two other localities. An amalgam of Hg and Ag is sometimes found native, iodide, chloride, and minute quantities of selenide, of Hg are also known to occur

Preparation—1 By distilling *cinnabar* in a regulated supply of air, condensing the Hg in a suitable apparatus, and allowing the SO_2 to escape—2 By heating *cinnabar* with lime, CaS and CaSO_4 are formed, and the Hg distils and is condensed—3 By heating *cinnabar* with iron (smithy scales), Hg , FeS , and SO_2 are produced, the Hg is condensed in long chambers, or by downward distillation in a trough filled with water

To purify Hg from dust, &c, it may be filtered through a paper cone having a minute hole at the apex, or pressed through leather. Traces of metals in solution may be removed by leaving the Hg in contact with cold conc H_2SO_4 for some weeks, with frequent agitation, and then digesting with very dilute HNO_3Aq , or with HgNO_3Aq (Branchi, *R P* 6, 77, Wittstein, *R P* 65, 362) Karsten and Ulex (*A* 60, 210) recommend to rub the Hg in a basin for ten minutes, with 1/60th of its weight of FeCl_3Aq , S G 1.48 diluted with an equal weight of water, to pour off the liquid, which contains the foreign metals and some HgCl_2 , to wash with water, and then to dry the Hg by heating it. L Meyer (*B* 12, 437) has described a convenient apparatus for purifying Hg by bringing a fine stream of it into contact with FeCl_3Aq Bruhl (*B* 12, 204) shakes Hg with an equal volume of chromate solution, made by dissolving 5 grams $\text{K}_2\text{Cr}_2\text{O}_7$ in 1 litre water, and adding a few c.c. of H_2SO_4 , the shaking is continued until the red HgCrO_4 at first produced has disappeared, and the liquid is coloured green by $\text{Cr}_2(\text{SO}_4)_3$, the fine greyish powder which is formed, and which consists of oxides of foreign metals, is washed away by a rapid stream of water. The process is repeated, and the Hg is then shaken with pure water until no more greyish powder is formed. About half p.c. of Hg is lost. Crafts (*B* [2] 49, 856) removes Pb, Zn, Sn, and most other metallic impurities from Hg by placing the Hg in a slightly inclined glass tube, and aspirating a gentle current of air through the apparatus for about forty eight hours. The oxides of the foreign metals collect at the top. Ag cannot be removed by this method

Pure Hg may be obtained by distilling equal parts of *cinnabar* and burnt lime or Fe filings. Also by boiling pure HgCl_2Aq with pure Fe .

Also by heating HgO in a retort, and digesting the residual Hg , which contains a little HgO , with dilute HNO_3Aq or H_2SO_4 . Millon (*B J* 27, 110) prepares HgO (from which to make Hg) by shaking Hg for some time with dilute HNO_3Aq to remove foreign metals, washing, dissolving in such a quantity of HNO_3Aq that 1/10th of the Hg remains undissolved, evaporating to dryness, and heating.

After purifying Hg by one of the foregoing methods it is advisable to distil it. A very convenient apparatus for distilling Hg under reduced pressure is described by Wright (*Am S* [3] 22, 479, v also Weber, *Carl Rep* 15, 52, Weinhold, *Carl Rep* 15, 1).

Properties—A very lustrous metal, white, with the slightest tinge of blue. Exists as a very mobile liquid at ordinary temperatures, and does not solidify above -38.5° . Hg boils at 360° , but it is very easily volatilised, even at -13° sufficient Hg is vaporised to produce a daguerreotype by twenty four hours' exposure (Regnault, *C R* 73, 141/2). According to Merget (*C R* 73, 1386) solid Hg at -44° is very slowly vaporised. Solid Hg is a tin-white, ductile mass of octahedral and needle shaped crystals. It may be cut with a knife. Hg is a very coherent liquid. By trituration with sugar, grease, sulphur, chalk, &c., or by agitation with ether, turpentine, and some other liquids, Hg appears as a grey powder, which consists of minute globules of Hg separated by the foreign matter present (*extinction or deadening of mercury*). Finely divided Hg is also obtained by mixing about equal parts of SnCl_2 , dissolved in HClAq , and HgCl_2 , dissolved in hot water ($\text{SnCl}_2\text{Aq} + \text{HgCl}_2\text{Aq} = \text{SnCl}_4\text{Aq} + \text{Hg}$). In this state of fine division, Hg is slowly oxidised by contact with air. Pure Hg adheres very slightly to glass. When foreign metals are present the Hg leaves a blackish film on glass. A globule of pure Hg should roll down a slightly inclined surface without losing its round form, and without leaving any streak behind it. When shaken in a bottle with dry air it should not form any black powder.

Pure Hg is not oxidised by exposure to air at ordinary temperatures, when heated to near its B.P. HgO is slowly formed [Berthelot (*C R* 91, 871) asserts that pure Hg is very slightly oxidised in air]. Hg obtained in a state of fine division by trituration, e.g. with chalk, is slowly oxidised at the ordinary temperature. Ozone oxidises Hg at ordinary temperatures (Volta, *G* 9, 521, cf *Reactions*, No 2). Hg combines directly with O , S , and the halogens, it alloys with most of the metals, in some cases forming definite compounds (v *Mercury, amalgams of*). Hg reacts with hot conc H_2SO_4 to produce HgSO_4 and SO_2 , with HNO_3Aq it produces HgNO_2 , $\text{Hg(NO}_3)_2$, or a basic nitrate, according to the temperature and the quantity of acid. HClAq does not react with Hg .

The atomic weight of Hg has been determined (1) by analysing HgO^f (Sefström, *S* 23, 328, Turner, *A* 13, 18, Erdmann & Marchand, *J pr* 31, 395), (2) by determining Cl in HgCl and HgCl_2 (Turner, *lc*, Svanberg, *J pr* 45, 468, Millon, *A Ch* [3] 18, 345), (3) by estimating Hg in HgS (Erdmann & Marchand, *J pr* 31, 400), (4) by determining S in Hg .

Hg is distinctly a metallic element. It forms salts by replacing the H of most acids. These salts belong to two series, HgX and HgX_2 , where $\text{X} = \text{NO}_2$, ClO_2 , $\frac{1}{2}\text{SO}_3$, PO_3 , &c. Both series are well represented by definite and stable salts. HgO dissolves in molten KOH , and crystals of $\text{K}_2\text{O HgO}$ are obtained on cooling. The compound $\text{Na}_2\text{O HgO}$ is said also to exist. HgS dissolves in NaHSaAq and conc KHSaAq . The compound $\text{K}_2\text{S HgS} \cdot 5\text{H}_2\text{O}$ has been isolated. The existence of these compounds shows that HgO and HgS are slightly acidic towards K_2O and KHS .

The molecular weight of Hg has been directly determined, the molecule is monatomic. The atom of Hg is divalent in the gaseous molecules HgCl_2 , HgBr_2 , and HgI_2 . The molecular formula of calomel is probably HgCl , if this is so, the atom of Hg is monovalent in this molecule.

Hg is related to Mg and Zn , and more distantly to Be , Ca , Sr , and Ba (v **MAGNESIUM GROUP OF ELEMENTS**, p 165, and cf **CLASSIFICATION**, vol II pp 204, 207).

Reactions—1 Heated in *air* or *oxygen*, to near its B.P., Hg slowly forms HgO .—2 *Ozone* produces some Hg_2O at ordinary temperatures, perfectly dry ozone does not react with dry Hg (Shenstone & Cundall, *C J* 51, 619).—3 Hg is oxidised by agitation with solution of *potassium permanganate*, Hg_2O is formed if the solution is cold, and HgO if hot (Kirchmann, *Ar Ph* [2] 150, 203).—4 Hg does not react with *hydrochloric acid*.—5 *Sulphuric acid*, when hot and conc, forms HgSO_4 , or Hg_2SO_4 , if there be an excess of Hg and the acid is not very hot, and SO_2 , dilute $\text{H}_2\text{SO}_4\text{Aq}$ scarcely acts on Hg .—6 *Nitric acid*, cold and dilute, forms HgNO_2 , with hot HNO_3Aq and excess of Hg , basic mercurous nitrates, $x\text{Hg}_2\text{O} \cdot y\text{N}_2\text{O}_5$, are formed, excess of hot HNO_3Aq produces $\text{Hg(NO}_3)_2$.—7 Warm conc *hydrobromic* and *hydrochloric* acids produce HgBr_2 and HgI_2 , respectively (cf *Berthelot*, *A Ch* [6] 16, 433).—8 *Hydrogen sulphide*, or *alkaline polysulphides*, produce HgS .—9 With *nitrogen tetroxide*, forms HgNO , and NO (Ramsay, *B* 13, 3154).

Combinations—1 Hg combines with the *halogens*, forming HgX or HgX_2 , according to the relative quantities of the reacting bodies.—2 With *oxygen*, Hg forms Hg_2O and HgO .—3 With *sulphur* and *selenium*, HgS and HgSe are produced.—4 Hg probably combines with *phosphorus*, but no definite compound has been isolated with certainty.

Detection and Estimation—Solid Hg compounds are decomposed by drying, mixing well with dry Na_2CO_3 , and heating strongly in a small tube closed at one end, Hg is volatilised, and condenses on the cold part of the tube in minute globules. Mercurous salts in solution give a white pp (HgCl) with HClAq , or a soluble chloride, this pp is blackened by NH_3Aq with formation of $\text{NH}_2\text{Hg}_2\text{Cl}$. Mercurous salts are oxidised to mercuric salts by boiling with HNO_3Aq . Mercuric salts are not pptd by HClAq , H_2SAq , or a soluble sulphide, ppts black HgS , addition of a small quantity of the reagent causes the formation of a compound of HgS with the original salt present, this pp is white, yellow, or brown, according to the quantity of reagent used.

Hg is sometimes estimated by heating its dry compounds with powdered CaO, condensing the Hg under water, transferring to a weighed crucible, drying by blotting paper and then over H_2SO_4 , the metal is sometimes pptd by SnCl_2 or H_3PO_4 at c 60° , dried, and weighed. Hg is also estimated as HgCl_2 by adding HClAq , then nearly neutralising with KOH Aq , adding K or Na formate, digesting for some days at 60° – 70° (Hg is pptd at boiling temperature), collecting the HgCl_2 on a weighed filter, washing, drying at a low temperature and weighing. Hg is also determined as HgS , by pptn from HgCl_2Aq by H_2S , and collection on a weighed filter. If the ppt is formed from solutions containing HNO_3Aq or FeCl_2Aq &c, free S is pptd with the HgS , the ppt may then be heated with CaO and the Hg collected, or heated in Cl, the HgCl_2 passed into water, and Hg pptd by SnCl_2 . Hg may also be determined by depositing it by electrolysis on a weighed Pt dish. A mercurous salt, in presence of mercuric, may be estimated by ppg by HClAq , from a cold very dilute solution, not more than a very small quantity of HNO_3 being present.

There are several methods for the volumetric determination of Hg, that described by Hannay, which is based on the fact that the turbidity produced in mercuric salt solutions by a few drops of NH_3Aq is removed by a definite quantity of KCN Aq , is said to give satisfactory results. (For details of the methods *see Manuals of Analysis*.)

Mercury, alloys of, *v* next line

Mercury, amalgams of The alloys of Hg are usually called *amalgams*, the word is supposed to be an alchemist's anagram of $\mu\lambda\alpha\gamma\mu\alpha$ = a soft mass. Amalgams are known of most of those metals which have been fairly well studied. Amalgams are formed by mixing the other metal with Hg, by ppg the other metal on Hg (or Hg on the other metal), and by placing the other metal in contact with Hg and a dilute acid. Many amalgams are definite compounds, others seem to be merely solutions of metals in Hg, and others are probably solutions of definite compounds in excess of Hg. Amalgams of Bi, Pb, Sn, and Zn, for instance, retain Hg at 360° (B P of Hg), but not at 410° . Crystalline amalgams of K and Na, K₂Hg and Na₂Hg, are obtained by heating solutions of K and Na in Hg to 440° .

The best known amalgams are those of Al, Ba, Bi, Cd, Cs, Ca, Cr, Co, Cu, Au, Fe, Pb, Mg, Mn, Ni, Os, Pd, Pt, K, Ag, Na, Sr, Ti, Sn, and Zn. For brief accounts of these amalgams, with the exception of those of Cu which are described below, *v* the various metals, **ALUMINUM, BARIUM, &c**, the articles, **AMALGAMS**, vol 1 p 149, and **ALLOYS**, vol 1 p 132, should be consulted. An interesting paper on *Amalgams*, by Dudley, will be found in *Proc Amer Ass for Advancement of Science*, 1890 145.

COPPER AMALGAMS (should have been described under **COPPER, ALLOYS OF**, vol 1 p 254). Amalgams of Cu are formed by placing Cu foil in HgNO_3Aq , by triturating 3 parts Hg with a mixture of 1 part very finely divided Cu and a few drops of HgNO_3Aq , by triturating Hg with NaCl and verdigris, by making Hg the negative electrode during electrolysis of CuSO_4Aq , by immersing Na-amalgam, or Zn amalgam, in

CuSO_4Aq , and in some other ways. By dissolving Cu in Hg, and removing excess of Hg by pressure, Joule obtained an amalgam having the composition CuHg (*Chem Gazette*, 1850 339). By heating amalgams rich in Hg, De Souza obtained Cu_2Hg at c 410° , and Cu_3Hg at c 360° (*B* 9, 1050). By ppg Cu from CuSO_4Aq by Fe, washing well, moistening with HgNO_3Aq , and rubbing with Hg, amalgams are obtained which harden after a time. The amalgam with from 25 to 33 p.c. Cu, may be obtained soft and plastic by heating nearly to 360° , and kneading for some time in a warm mortar, this amalgam slowly hardens without either contracting or expanding, it is used for stopping teeth (*v* Von Gersheim, *A* 70, 344).

Mercury, ammonio compounds of; *v* **MERCURAMMONIUM COMPOUNDS**, p 206

Mercury, antimonides of, *v* vol 1 pp 285–6

Mercury, antimonide of A substance of the nature of an amalgam is formed by triturating together Sb and Hg, little is known of its composition and properties, it is very easily decomposed.

Mercury, arsenates of, *v* vol 1 p 309

Mercury, arsenide of Bergmann obtained what he thought was a compound of 1 pt As with 5 pts Hg by heating Hg and As together.

Mercury, arsenites of, *v* vol 1 p 306

Mercury, bromides of Two bromides of Hg are known, HgBr and HgBr_2 . Mercuric bromide has been vapourised, its mol w is 359.3 = HgBr_2 . Mercurous bromide has also been vapourised, the results indicate the mol w 279.55 = HgBr , but it is not certain whether partial dissociation into HgBr , and Hg occurred during vapourisation (*v* *infra*, also *Mercurous chloride*, p 215). Both HgBr and HgBr_2 form double compounds with the bromides of metals more positive than Hg.

MERCUROUS BROMIDE HgBr (*Mercury proto or mono bromide*). Mol w 279.55 (?). H F [HgBr] = 25.475 (Thomsen, *Z P C* 2, 21).

Preparation—1 By subliming an intimate mixture of 80 pts Br and 200 pts Hg—2 By adding KBrAq to HgNO_3Aq —3 By heating saturated HgNO_3Aq , as free as possible from HgO and slightly acidified with HNO_3Aq , with Br, decanting, and allowing to cool in the dark (Stroman, *B* 20, 2818)—4 By adding alcoholic solution of Br to cold conc HgNO_3Aq (Stroman, *l c*).

Properties and Reactions—As prepared by method 3 (*supra*), forms small, white, nacreous, tetragonal, scales, prepared by method 2, appears as yellow, crystalline, spangles (Stroman, *l c*). SG 7.307 (Karsten, *S* 65, 394). Sublimes at 340° – 350° . Melts c 405° (?) (Carnelley, *C J* 33, 277). VD 146.3 (according to Mitscherlich (*P* 29, 193)). Tasteless and odourless. Insol in water. Hot conc H_2SO_4 dissolves HgBr with evolution of SO_2 , dissolves slowly in hot HNO_3Aq SG 1.42, decomposed by hot HClAq dil or conc, decomposed by NH_3Aq or KOH Aq , forming NH_4Br or KBr , and leaving a black residue which contains Hg (Stroman, *l c*). Slowly decomposed by boiling KBrAq , giving HgBr_2 and Hg. Soluble in some NH_4 salt solutions.

Combinations—Two compounds with *strontium chloride* are described by Löwig (*P* 14, 485). By dissolving HgBr in boiling SrBr_2Aq , allowing

to cool, pouring off from separated HgBr , and evaporating, crystals of $6\text{HgBr}\cdot\text{SrBr}$, separate, by dissolving these crystals in water, filtering from HgBr which separates, and evaporating, a very soluble crystalline compound $2\text{HgBr}\cdot\text{SrBr}$, is obtained

MERCURIC BROMIDE HgBr_2 (*Dibromide of Mercury*) Mol w 359.3 HF [HgBr_2] = 41.880 (Thomsen, *Z P C* 2, 21)

Preparation — 1 By dissolving HgO in HBrAq , and crystallising — 2 By bringing Hg into slight excess of Br , warming to remove uncombined Br , and subliming — 3 By heating an intimate mixture of HgSO_4 with rather more than its own weight of KBr , the HgBr_2 , which sublimes is said to contain HgBr — 4 By adding KBrAq to $\text{Hg}(\text{NO}_3)_2\text{Aq}$, evaporating as long as HgBr_2 crystallises out, and crystallising from alcohol — 5 By agitating Hg with water, adding Br as long as its colour is removed, boiling, filtering, allowing to crystallise, and drying at $c\ 160^\circ$ — 6 By adding excess of Br to a slightly acid solution (S G 1 197) of $\text{Hg}(\text{NO}_3)_2$, HBrOAq is formed in the reaction (Sievers, *B* 21, 647)

Properties — White rhombic prisms, isomorphous with HgCl_2 , $a\ b\ c = 6817\ 1\ 9975$ (Hjorthal, *Z K* 3, 362) S G 5 9202 (Karsten, *S* 65, 394), 5 7298 at 16° , 5 7461 at 18° (Clarke's *Specific Gravity Tables*, new ed 32) V D 175.5, Mitscherlich (*P* 29, 193) Melts at 244° (Carnelley a Williams, *C J* 37, 127) Can be sublimed unchanged S 1 06 at 9° , 20–25 at 100° (Lassaigne) Very sol in alcohol and ether HgBr_2Aq reddens litmus

Reactions — 1 Heated with phosphorus, arsenic or antimony, forms bromide of P, As, or Sb — 2 Decomposed, yielding HgBr , by sunlight, or contact with copper or mercury, or by mixing with cuprous bromide dissolved in HBrAq — 3 HgBr_2Aq with ammonia gives a white pp of $\text{Hg}_2\text{Br}_2\text{NH}_3$ (Mitscherlich, *J pr* 19, 455) — 4 With sodium hypochlorite, HgBr_2Aq gives oxychlorides $x\text{HgO}\cdot y\text{HgCl}_2$ (Rammel-berg) — 5 With hypochlorous acid, HgCl_2 and $\text{Hg}(\text{BrO})_2$, are formed (Balard) — 6 Decomposed by nitric or sulphuric acid, giving off Br — 7 Oxybromides, $x\text{HgO}\cdot y\text{HgBr}_2$, are obtained by boiling HgBr_2Aq with mercuric oxide — 8 Mixed with mercuric iodide and crystallised from ether or acetone, HgI_2Br is obtained, this compound is also formed by the action of an alkyl iodide, e.g. EtI , on HgBr_2 dissolved in acetone (Oppenheim, *B* 2, 571) (*v Mercury, iodobromide of*, p 221)

Combinations — 1 With hydrobromic acid to form bromomercuric acid HHgBr_2 (*v infra*) — 2 Combines with many bromides of more positive metals than Hg , to form salts regarded by Von Bonsdorff as bromomercurates (*P* 19, 339) These salts are obtained by evaporating solutions of the component bromides, the more important are $\text{HgBr}\cdot\text{KBr}$ and $\text{HgBr}\cdot 2\text{KBr}$, $\text{HgBr}\cdot\text{MgBr}$, and $2\text{HgBr}\cdot\text{MgBr}_2$, $\text{HgBr}_2\cdot\text{SrBr}$, and $2\text{HgBr}_2\cdot\text{SrBr}_2$ (Löwig, *P* 14, 485) Salts containing NaBr , CaBr , BaBr , and ZnBr , were also obtained by Von Bonsdorff (*loc*) Bromomercuric acid, HHgBr_2 , was obtained by Neumann (*M* 10, 286), in long transparent needles, by slightly warming excess of HgBr_2 with HBrAq , filtering through asbestos, and cooling to between 0° and -4° . This acid is

readily decomposed by moisture or heat Solution of HgBr_2 in HBrAq reacts with alkalis to give $\text{HgBr}_2\cdot 2\text{MX}$ ($\text{M} = \text{alkali metal}$), the heat produced is $c\ 27,200$ for 2MOH , the solution of HgBr_2 in HBrAq probably contains the acid H_2HgBr_4 — 3 With mercuric cyanide and potassium cyanide, forms lustrous tablets of $\text{HgBr}_2\cdot\text{HgCy}_2\cdot 2\text{KC}_y\ 4\text{H}_2\text{O}$ (Geuther, *A* 29, 325) With mercuric cyanide and zinc cyanide, forms transparent prisms of $\text{HgBr}_2\cdot\text{HgCy}_2\cdot\text{ZnCy}_2\cdot 8\text{H}_2\text{O}$ (Varet, *C R* 109, 809) — 4 Heated with mercuric sulphide, forms $\text{HgBr}_2\cdot 2\text{HgS}$ (Schneider, *P* 115, 167), this salt is also obtained by boiling HgBr_2Aq with freshly ppd HgS (H Rose, *P* 13, 59) (*v Mercuric sulphide, Combinations*, No 4, p 225)

Mercury, bromide of, *v Mercury, iodobromide of*, p 221

Mercury, bromosulphide of, *v Mercuric sulphide, Combinations*, No 4, p 225

Mercury, chlorides of Two chlorides are known, HgCl and HgCl_2 . The molecular weight of the latter has been determined from the V D of the compound The numbers obtained for the V D of the former agreed with the formula HgCl , but it was shown that the vapour produced by heating mercurous chloride contained Hg and HgCl_2 , hence the V D could not decide between the possible formulæ HgCl and HgCl_2 . More recently it has been found that the V D calculated from observations of V D of mercurous chloride vapourised into an atmosphere of HgCl_2 agrees with that required by HgCl (*v infra*)

MERCUROUS CHLORIDE HgCl (*Protochloride of mercury Calomel*) Mol w very probably 235.17 Sublimes at 400° – 500° without melting S G 6 993 (Karsten, *S* 65, 394), to 7 176 (Hassenfratz, *A Ch* 28, 3) V D 118.6 at 440° (Deville a Troost, *C R* 45, 821), 120.8 (Mitscherlich, *P* 29, 193) V D calculated for $\text{HgCl} = 117.58$ Odling showed that gold leaf is amalgamated when exposed to calomel vapour at $c\ 400^\circ$, hence he concluded that the vapour contained Hg , and that therefore the observed V D did not prove the formula HgCl (*J* 1864 280) Debray found that only a limited portion of the calomel vapourised at 440° is decomposed with separation of Hg (*C R* 83, 330), hence it appears impossible that calomel should have the molecular formula HgCl , else the observed V D at $c\ 440^\circ$ would be considerably greater than 120 (calc for $\text{HgCl}_2 = 235.16$) In 1881, Fielet showed that when a mixture of mercurous and mercuric chlorides is heated to $c\ 400^\circ$ in a Pt tube, containing a tube of silver-gilt traversed by a stream of cold water, not a trace of Hg is deposited on the gilt tube He then determined the V D of a mixture of mercurous and mercuric chlorides, and calculated the V D of the mercurous chloride in the mixed vapours, the results were 115.9 and 120.1, hence the molecular formula of calomel is most probably HgCl (*G* 1881 341) SH at 7° – 99° , 05205 (Regnault, *A Ch* [3] 1, 129) Crystallises in tetragonal forms, $a\ c = 1.17414$ HF [HgCl] = 32,600 (Thomsen, *Z P C* 2, 21) For T C *v* Von Lang, *P* 135, 29, for heat of vaporisation, *v Manganese, C R* 67, 877

Occurrence — As horn quicksilver, in tetragonal crystals. S G 6 482.

Formation.—1 By passing Cl over excess of Hg; action proceeds slowly at ordinary temperatures, rapidly at near B P of Hg.—2 By reducing HgCl_2Aq , saturated at 50° , by SO_2 (Wohler, *A* 90, 124, Sartorius, *A* 96, 325)—3 By reducing HgCl_2Aq by oxalic acid in sunshine (Eder, *B* 13, 166)—4 By shaking Hg with FeCl_2Aq —5 By ppg a mercurous salt by HClAq —6 By heating HgCl_2 with Hg—7 By heating HgSO_4 with Hg and NaCl —8 By triturating Hg with NaCl , $\text{Fe}_2(\text{SO}_4)_3$, and a little water, till the metal has lost its fluidity, and subliming $(\text{Fe}_2(\text{SO}_4)_3 + 6\text{NaCl} + 2\text{Hg} = 3\text{Na}_2\text{SO}_4 + 2\text{FeCl}_2 + 2\text{HgCl})$

Preparation.—1 An intimate mixture of 4 pts HgCl_2 with 3 pts Hg is made by moistening with alcohol and triturating until the Hg loses its fluidity, the mixture is gently heated for a few hours, again pulverised, and then slowly sublimed in a flask or retort, not more than a quarter filled with the mixture and placed on a thin layer of sand.—2 4 pts Hg, 9 pts dry HgSO_4 , and 3 pts water are very intimately mixed, a quantity of NaCl equal to the weight of the Hg and HgSO_4 , used is added, and the mixture is slowly heated till HgCl sublimes (Planche, *A Ch* 66, 168)—3 A well-pulverised mixture of 1 pt NaCl , $1\frac{1}{2}$ pts NaCl , and $2\frac{1}{2}$ pts Hg is heated with 2 pts conc H_2SO_4 , until HgCl sublimes.—4 A warm dilute solution of HgNO_3Aq , mixed with a little HNO_3 , to prevent formation of basic salts, is ppd by excess of dilute NaClAq containing a little HCl , the liquid is heated for some time in contact with the pp which is then thoroughly washed with cold water in the dark (Schæele, *cf* Frautwein, *R* P 11, 72, 12, 155, Mialhe, *J Ph* 22, 586)—5 Cl is passed into HgNO_3Aq , the pp of HgCl mixed with HgCl_2 , is washed with hot water till HgCl_2 is all dissolved, the HgCl is then crystallised from warm HgNO_3Aq (Sievers, *B* 21, 647)

Properties.—White, semi transparent, tetragonal, prisms, if sublimed quickly, forms a fibrous mass of small crystals. When powdered, calomel shows a slight lemon yellow colour. Highly refractive and dispersive. Tasteless and odorless. Sublimes without melting. Almost quite insol water, alcohol, ether, and dilute acids. Sl sol cold, more sol hot, HgNO_3Aq (*v* Debray, *O R* 70, 995, *cf* Dreehsel, *J pr* [2] 24, 44). Boiled with HClAq , HgCl_2 goes into solution, and Hg is separated, with conc hot H_2SO_4 , HgCl_2 and HgSO_4 are formed. HgCl is decomposed by solutions of alkalis, alkaline earths, and alkaline carbonates, with ppn of Hg_2O . For experiments on V D of calomel, *v supra*

Reactions.—1 Exposed to sunlight, HgCl darkens with separation of Hg (for action of heat on HgCl *v supra*)—2 Partly decomposed by aqueous vapour or boiling water, with production of HgCl_2 and Hg—3 Decomposed by many metals when heated with them in presence or absence of water, giving metallic chlorides and Hg—4 Triturated with iodine and water, HgCl_2 and HgI_2 are produced (Planche & Soubeiran, *J Ph* 12, 651)—5 Heated with a little sulphur, HgS and HgCl_2 are formed, with excess of S, the products are HgS and S_2Cl_2 —6 Heated in phosphorus vapour, HgCl yields PCl_2 and Hg phosphite (Davy).—7 By heating an intimate

mixture of 3 pts HgCl with 1 pt arsenic, a sublimate is obtained consisting in part of yellow tetrahedral crystals, according to Capitaine (*J pr* 18, 422) these crystals are *mercuro-arsenic chloride* AsHgCl . The compound is decomposed by hot water to As Hg amalgam, As_2O_3 and HCl , it is partly decomposed by heat, giving Hg, As, and AsCl_3 —8 Reduced by sulphurous acid, also by hot stannous chloride solution, with separation of Hg—9 Cold sulphuric acid has no action on HgCl , the hot conc acid forms HgCl_2 , HgSO_4 , and SO —10 Dissolved by hot nitric acid with evolution of NO , the solution contains $\text{Hg}(\text{NO}_3)_2$ and HgCl_2 —11 Boiling hydrochloric acid forms HgCl_2 and Hg, boiled in an open vessel with water and a little HCl , no Hg is separated, but HgCl_2 goes into solution—12 Decomposed by *hydrocyanic acid* solution, forming HgCy , Hg, and HCl —13 With solution of *alkali chlorides* forms HgCl_2 , which combines with the excess of alkali chloride to form double salts, some of which are soluble and some insoluble—14 Digested with solutions of *alkali iodides*, or *iodide of magnesium*, or *von*, HgI is separated, and metallic chloride goes into solution—15 Solutions of *alkalis* form Hg_2O and alkali chloride, heated with solid alkalis, Hg, O, and alkali chloride are produced—16 *Ammonia* produces black NH_4HgCl (*v* MERCURAMMONIUM COMPOUNDS)—17 Heated with *carbonates of calcium, barium, or magnesium*, Hg, Hg_2O , and HgO are separated, and CO is evolved (Buchner, *R P* 3, 31, 4, 289, Vogel, *R P* [3] 1, 34)—18 With *alkali sulphides* in solution, Hg separates, and a double sulphite of Hg and alkali metal goes into solution—19 Rubbed with *antimony tri* or *penta sulphide*, HgS and SbCl_3 are formed

Testing calomel for impurities.— HgCl some times contains HgCl_2 , HgNO_3 , or $\text{Hg}(\text{NO}_3)_2$, or Hg. HgCl_2 is detected by shaking with water, filtering, and adding SnCl_2Aq , when a white cry pp is produced. Bonnewyn (*Bl* [2] 4, 201) says that $\frac{1}{50000}$ pt of HgCl_2 in HgCl may be detected by immersing a clean knife blade in the calomel moistened with alcohol or ether, if HgCl_2 is present a black spot is formed on the blade. HgNO_3 or $\text{Hg}(\text{NO}_3)_2$ is detected by heating, when NO_2 is evolved. Hg may be detected by examination under the microscope. HgCl may be adulterated with powdered heavy spar, &c., this remains unchanged on sublimation. Adulteration with gum or other organic material is detected by the smell produced on heating.

Combinations.—1 With *sulphur chloride*, to form $2\text{HgCl}_2\text{SCL}_2$, produced by long continued warming HgCl with S_2Cl_2 , also by heating an intimate mixture of 31 pts HgCl_2 and 2 pts S in a dish covered with a funnel, on to which the double compound sublimes, also by heating As_2S_3 with HgCl_2 .

$(7\text{HgCl}_2 + \text{As}_2\text{S}_3 = 2\text{AsCl}_3 + 3\text{HgS} + 2\text{Hg}_2\text{SCL}_2)$
Forms rectangular needles, which melt to a brown liquid, and volatilise without decomposition, decomposed by water (Capitaine, *J pr* 18, 422)—2 With *stannous chloride* to form $2\text{HgCl}_2\text{SnCl}_2$. Produced by heating an amalgam of 8 pts Sn with 1 pt Hg mixed with 24 pts HgCl_2 , and subliming. Forms white dendritic crystals, partially decomposed by heat;

wholly decomposed by water, with formation of SnCl_2 which reduces the HgCl (Capitaine, *J pr* 18, 422)—3 H Rose (*P* 44, 325) states that HgCl combines with sulphur dioxide

MERCURIC CHLORIDE HgCl_2 (*Perchloride of mercury Corrosive sublimate*) Mol w 270.54 [288*] (Carnelley, *C J* 33, 276) (303*) (Carnelley & Williams, *C J* 33, 262) S G 6.223 (Playfair & Joule, *C S Mem* 2, 401), 5.418 (Schroder, *P* 107, 113) V D 136.3 (Mitscherlich, *P* 29, 193) S H 12°-45° 064 (Kopp, *Tr* 155, 71), 13°-98° 06889 (Regnault, *A Ch* [3] 1, 129) S 5.73 at 0°, 6.57 at 10°, 7.39 at 20°, 8.43 at 30°, 9.62 at 40°, 11.34 at 50°, 13.86 at 60°, 17.29 at 70°, 24.32 at 80°, 37.05 at 90°, 53.96 at 100° (Poggiale, *A Ch* [3] 8, 463) S cold alcohol 43.5, boiling alcohol 86.2, S ether 33, S glycerin 7 (Fairley, *M S* [3] 9, 685) Crystallises in two forms belonging to the trimetric system (i) crystals from alcoholic solution, $a:b:c = 7.254:1:1.0686$, (ii) crystals by sublimation, $a:b:c = 9.347:1:3.396$ (v Mitscherlich, *P* 28, 118, Von Lang, *W A B* 45, 119) H F [Hg_2Cl_2] = 64,490 (Thomsen, *Z P C* 2, 21)

Occurrence—In a volcanic district on Ternate, one of the Molucca islands (Frenzel, *Min Metall* 1877 305)

Formation—1 By heating Hg in excess of Cl 2 By dissolving HgO in hot HClAq , and evaporating 3 By dissolving Hg in hot HClAq containing some HNO_3 , evaporating, and recrystallising from hot water—4 By adding excess of Cl to a slightly acid solution of $\text{Hg}(\text{NO}_3)_2$ (Sievers, *B* 21, 617)

Preparation—1 An intimate mixture of equal parts NaCl and Hg_2SO (obtained by boiling 4 pts Hg with 5 pts conc H_2SO_4 till a dry mass is formed), to which a little MnO_2 has been added (to prevent formation of HgCl from Hg_2SO , which may be present), is slowly heated in a long necked flask or retort, HgCl_2 sublimes on the cooler parts of the apparatus. The operation must be conducted in a good draught cupboard because of the very poisonous nature of HgCl_2 —2 Boiling conc HgNO_3Aq is mixed with conc HClAq as long as a pp forms, the pp of HgCl is boiled with as much HClAq as was used in its formation ($\text{HgNO}_3\text{Aq} + 2\text{HCl} = \text{HgCl}_2\text{Aq} + \text{H}_2\text{O} + \text{NO}_2$), crystals of HgCl_2 separate on cooling, they may be recrystallised from hot water

Properties—Translucent crystals, forming a white powder when crushed HgCl_2 has a disagreeable metallic taste, it is extremely poisonous Melts at 288° (*v supra*) to a colourless liquid; according to Haass, HgCl_2 does not melt when heated if the pressure is less than 120 mm (*B* 13, 2203) Easily sol water, sol alcohol, ether, and glycerin (*v supra*) Schröder (*J R* 1886 18) gives the following table, showing the S G of aqueous and alcoholic solutions of HgCl_2 , and the percentage of HgCl_2 in these solutions—

Aqueous solutions of HgCl_2 .

HgCl_2Aq reacts slightly acid to litmus On boiling HgCl_2Aq some HgCl passes off with the steam HgCl_2Aq is decomposed by light with evolution of O and formation of HCl and Hg oxychloride (*cf* V Meyer, *B* 20, 2970)

Reactions—1 Many metals decompose HgCl_2 when heated with it, forming HgCl or Hg , such metals are Sb, As, Bi, Cu, Fe, Pb, Ni, Sn Many metals also reduce HgCl_2 in aqueous solution, generally ppg HgCl and Hg , Cd, Fe, and Zn pp Hg only—2 Reducing agents, e.g. SnCl_2Aq , SO Aq , formic acid, oxalic acid, produce HgCl (*cf* I der, *B* 13, 166, also Wurtz's *Dictionnaire*, *Suppl* p 1066)—3 With many carbon compounds, HgCl_2 forms H_2Cl and HCl (the H being withdrawn from the C compound)—4 HgCl_2 is not decomposed by sulphuric or nitric acid, it dissolves fairly easily in HNO_3Aq —5 Dissolves in hot conc hydrochloric acid, on cooling, a white crystalline mass is obtained which has the composition 2HgCl HCl according to Boullay (*A Ch* 34, 243, *cf* *Combinations*, No 1)—6 According to Fairley (*B A* 1875 42), hypochlorites reduce HgCl_2 to HgCl —7 Albumen is rapidly coagulated and ppd by HgCl_2Aq , white of egg serves as an antidote to poisoning by corrosive sublimate—8 Boiled with mercuric oxide, oxychlorides are obtained (*v* Mercury, oxychlorides or, p 223)—9 Alkalis produce HgO and alkali chloride—10 Normal potassium or sodium carbonate ppts HgO , (*K* or *Na*) HCO_3 is also formed, and this reacts with the rest of the HgCl_2 to pp oxychlorides—11 Potassium (or sodium) hydrogen carbonate produces various oxychlorides (*q v* p 223)—12 Phosphorus trihydride produces a black pp when passed into HgCl_2 dissolved in water or alcohol, on continuing the passage of PH_3 , the pp becomes yellow, and then has the composition $\text{P.Hg}, 3\text{HgCl}_2, 3\text{H}_2\text{O} = 2(\text{PHg}_2\text{Cl HgCl}_2) 3\text{H}_2\text{O}$, the solution contains HCl This compo is known as *dimercuriophosphonium mercuric chloride*, it must be washed quickly with cold water, and dried over H_2SO_4 *in vacuo*, it is decomposed by hot water, giving Hg , HCl , and H_3PO_4 , heat produces HCl , Hg , and H_3PO_4 (H Rose, *P* 40, 75)—13 Arsenic trihydride produces a brown yellow pp in HgCl_2Aq This pp has the composition $\text{AsHg}_2\text{Cl HgCl}_2$, it is known as *dimercuriarsonium-mercuric chloride* The pp is washed with cold water and quickly dried over H_2SO_4 *in vacuo*, it is decomposed by water to Hg , As_2O_3 , and HCl (H Rose, *P* 51, 123)

Combinations—1 With hydrochloric acid, according to Boullay (*A Ch* 34, 243) the compound 2HgCl HCl is obtained by dissolving HgCl_2 in hot conc. HClAq , and cooling, this

compound forms a crystalline lustrous mass which melts by the heat of the hand (v also Ditte, *O. R.* 92, 853) Neumann (*M* 10, 236) obtained *chloromercuric acid* HHgCl_2 by gently warming excess of HgCl_2 with HClAq , filtering through asbestos, and cooling to between 0° and -4° . This acid is very readily decomposed by heat or moisture. Solutions of HgCl_2 in HClAq react with alkalis to form $\text{HgCl}_2 \cdot 2\text{MX}$ (M = alkali metal), the heat produced in the reaction is c 27,200 for 2MOH , the solution of HgCl_2 in HClAq probably contains the acid H_2HgCl_2 . Dry HCl passed over well-cooled HgCl_2 has no action (*N*, *lc*) — 2 With many chlorides and with some other salts. The chief compounds with other chlorides are the following (v Von Bonsdorff, *P* 17, 115) —

(i) With phosphorus pentachloride $3\text{HgCl}_2 \cdot 2\text{PCl}_5$. Pearl white needles, sublimes unchanged, decomposed by water, formed by heating the constituents together (Baudrimont, *A Ch* [4] 2, 45)

(ii) With alkali chlorides (a) With potassium chloride $2\text{KCl} \cdot \text{HgCl}_2 \cdot \text{H}_2\text{O}$, $\text{KCl} \cdot \text{HgCl}_2 \cdot \text{H}_2\text{O}$, $\text{KCl} \cdot 2\text{HgCl}_2 \cdot 2\text{H}_2\text{O}$. The first salt is formed by saturating KClAq with HgCl_2 at 30° , adding as much KCl as originally used, and evaporating. The second salt is produced by evaporating a solution of equal equivalents of KCl and HgCl_2 (Rammelsberg, *P* 90, 34). The third salt results by saturating KClAq at 60° with HgCl_2 and allowing to cool. The compound $6\text{KCl} \cdot 3\text{HgCl}_2 \cdot \text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ was obtained by Von Bonsdorff (*P* 33, 81) by adding CuCl_2Aq to a dilute solution of $\text{KCl} \cdot \text{HgCl}_2$. (b) With sodium chloride $2(\text{NaCl} \cdot \text{HgCl}_2) \cdot 3\text{H}_2\text{O}$, $2\text{NaCl} \cdot \text{HgCl}_2$. The first salt is obtained by adding NaCl to NaClAq saturated with HgCl_2 . The second salt is produced by adding alcohol to saturated NaClAq shaken with powdered HgCl_2 . (c) With rubidium chloride $2\text{RbCl} \cdot \text{HgCl}_2$, $\text{RbCl} \cdot 2\text{HgCl}_2$. Obtained, respectively, by evaporating a neutral solution of RbCl and HgCl_2 , by evaporating a solution of equal parts of the constituent salts, and by heating the second salt to 50° (Godeffroy, *Ar Ph* [3] 12, 47). (d) With ammonium chloride $2\text{NH}_4\text{Cl} \cdot \text{HgCl}_2 \cdot \text{H}_2\text{O}$ (*sal alembrothi*) is obtained by evaporating a solution of 1 pt NH_4Cl and 2 pts HgCl_2 , loses H_2O in dry air, isomorphous with the corresponding K salt. The other salts obtained are $\text{NH}_4\text{Cl} \cdot \text{HgCl}_2$, $2\text{NH}_4\text{Cl} \cdot 2\text{HgCl}_2 \cdot 2\text{H}_2\text{O}$ (Kane), $2\text{NH}_4\text{Cl} \cdot 9\text{HgCl}_2$, and $2\text{NH}_4\text{Cl} \cdot 3\text{HgCl}_2 \cdot 4\text{H}_2\text{O}$ (Holmes, *O N* 5, 351).

(iii) With alkaline earth chlorides (a) With calcium chloride $\text{CaCl}_2 \cdot 5\text{HgCl}_2 \cdot 8\text{H}_2\text{O}$, by saturating warm CaCl_2Aq with HgCl_2 , and cooling, by evaporating the mother liquor the salt $\text{CaCl}_2 \cdot 2\text{HgCl}_2 \cdot 6\text{H}_2\text{O}$ is obtained. (b) With strontium chloride $\text{SrCl}_2 \cdot 2\text{HgCl}_2 \cdot 2\text{H}_2\text{O}$. (c) With barium chloride $\text{BaCl}_2 \cdot 2\text{HgCl}_2 \cdot 2\text{H}_2\text{O}$. (d) With magnesium chloride $\text{MgCl}_2 \cdot 3\text{HgCl}_2 \cdot 5\text{H}_2\text{O}$ and $\text{MgCl}_2 \cdot \text{HgCl}_2 \cdot 6\text{H}_2\text{O}$.

(iv) With chloride of zinc $\text{ZnCl}_2 \cdot \text{HgCl}_2 \cdot 4\text{H}_2\text{O}$, by evaporating a mixed solution of the constituents. Analogous salts with CuCl_2 , CoCl_2 , NiCl_2 , and FeCl_2 have been obtained.

The chief compounds with oxyacids are the following. —

(i) With ammonium sulphite

$3\text{HgCl}_2 \cdot 2(\text{NH}_4)_2\text{SO}_3$. By adding hot saturated HgCl_2Aq to cold $(\text{NH}_4)_2\text{SO}_3\text{Aq}$ (*P de Saint-Gilles*, *A* 84, 266, 269).

(ii) With potassium chromate, and dichromate (a) $\text{HgCl}_2 \cdot \text{K}_2\text{Cr}_2\text{O}_7$, by cooling a warm solution of equivalents of the two salts (Millon, *A Ch* [8] 18, 388, Darby, *C S Mem* 1, 24).

(b) $2\text{HgCl}_2 \cdot \text{K}_2\text{CrO}_4$, by mixing solutions of the constituent salts in the ratio $2\text{HgCl}_2 \cdot \text{K}_2\text{CrO}_4$, adding HClAq sufficient to dissolve ppd HgCrO_4 , and evaporating (Darby, *lc*).

(iii) With ammonium dichromate (a) $\text{HgCl}_2 \cdot (\text{NH}_4)_2\text{Cr}_2\text{O}_7 \cdot \text{H}_2\text{O}$, by evaporating a solution of the constituents (Abel & Richmond, *C J* 3, 202, cf Darby, *C S Mem* 1, 24, Zephorovich, *W A B* 39, 17). (b) $\text{HgCl}_2 \cdot 3(\text{NH}_4)_2\text{CrO}_4$, by evaporating the mother liquor from the first salt (*A A R*, *lc*; cf Clarke & Stern, *Am. Ch* 3, 351).

(iv) With copper acetate

$2\text{HgCl}_2 \cdot \text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{CuO}$, deposited from a mixture of cold saturated solutions of HgCl_2 and $\text{Cu}(\text{O}_2\text{H})_2$ (Hutteroth & Wöhler, *A* 53, 142).

(v) With chlorochrometetrammonium chloride $6\text{HgCl}_2 \cdot \text{Cl}_2\text{Cr}_2\text{S}_2\text{NH}_4 \cdot \text{Cl}_4$, by spontaneous evaporation of a mixed solution of the two salts (Clève, *J* 1862 150).

3 Compounds of HgCl_2 with PHgCl and AsHgCl are known (a) *Dimercuriphosphonium mercuric chloride* $2(\text{PHgCl} \cdot \text{HgCl}_2) \cdot 3\text{H}_2\text{O}$, a yellow solid formed by passing PH_3 into HgCl_2 dissolved in water or alcohol (v *Reactions*, No 12).

(b) *Dimercuriarsonum - mercuric chloride* $\text{AsHg}_2\text{Cl} \cdot \text{HgCl}_2$, a brown yellow pp by passing AsH_3 into HgCl_2Aq (v *Reactions*, No 13) — 4 A compound of HgCl_2 with *mercuric sulphocyanide* — $\text{HgCl}_2 \cdot \text{Hg}(\text{CSN})_2$ — is obtained by the reaction of SOCl_2 with $\text{Hg}(\text{SCN})_2$ (McMurtroy, *C J* 55, 50).

Mercury, fluorides of Two are known, HgF and HgF_2 , the VD of neither has been determined. These fluorides are remarkably unstable both as regards the action of water and of heat.

MERCURIOS FLUORIDE HgF or Hg_2F_2 . Prepared by adding freshly $\text{ppd Hg}_2\text{CO}_3$ to HFAq so long as the salt is dissolved, and evaporating, also by adding recently prepared HgCl_2 to a solution of Ag_2CO_3 in HFAq , filtering from AgCl , and evaporating on a steam bath (Finkner, *A* 110, 142). Berzelius obtained HgF mixed with HgCl_2 by subliming a mixture of HgCl_2 with NaF . HgF is a light yellow, crystalline, powder. It is partly

dissolved, and partly decomposed to HF and Hg_2O , by water. Exposed to light when moist it is blackened. HgF may be heated to $c\ 200^\circ$ without change, above this temperature Hg sublimes and the glass vessel is corroded. HgF is decomposed by alkalis with separation of Hg_2O , the action of NH_4Aq is more complex. HgF absorbs NH_3 gas forming $\text{N}_2\text{H}_5\text{HgF}_2$ (*v. Mercurammonium compounds*, p 206). Combines with SiF_4 to form *Mercurus silicofluoride* $\text{Hg}_2\text{SiF}_6 \cdot 2\text{H}_2\text{O}$ (*v. Mercury, silicofluorides of*, p 224).

MERCURIC FLUORIDE HgF_2 . According to Fremy (*A Ch* [3] 47, 5), crystals of this compound are obtained by dissolving HgO in excess of HFAq , and evaporating the solution slowly over lime. Finkener (*P* 110, 628) obtained an oxyfluoride, $\text{HgF}_2 \cdot \text{HgO} \cdot \text{H}_2\text{O}$, by this method, by adding conc. HFAq (50 p c) to this oxyfluoride, it was suddenly changed to a white crystalline mass of $\text{HgF}_2 \cdot 2\text{H}_2\text{O}$ (Finkener, *Lc*). The hydrated fluoride is decomposed at 30° , giving H_2O , HF, and HgO . $\text{HgF}_2 \cdot \text{H}_2\text{O}$ (F) HgF_2 is decomposed by water with separation of HgO . Addition of slight excess of NH_4Aq to HgF_2 in HFAq ppts $\text{NH}_4\text{HgOF} \cdot \text{HF}$ (Finkener, *P* 110, 632). *Mercuric silicofluoride* $\text{HgSiF}_6 \cdot 6\text{H}_2\text{O}$ probably exists (*v. Mercury, silicofluorides of*, p 224). Berzelius obtained a compound of HgF_2 with NH_4F by treating HgF_2 with NH_4Aq . HgF_2 combines with HgS (*v. Mercuric sulphide, Combinations*, No 6, p 225).

Mercury, fluosulphide of, *v. Mercuric sulphide, Combinations*, No 6, p 225.

Mercury, fulminate of, *v. vol II* p 317.

Mercury, haloid compounds of. Two series of these compounds exist, HgX and HgX_2 . The molecular weights of HgCl , HgBr , and HgI , are known, the molecular weights of HgCl , HgBr , and HgI are probably as represented by these formulæ. The compound HgI HgI also exists, and a peroxide of Hg has been isolated. The mercurous compounds HgX are insoluble in water, except HgCl , which is partly dissolved, and partly decomposed, by water, the mercuric compounds HgX_2 are soluble in water, with the exception of HgF_2 , which is decomposed by water. The Hg haloid compounds combine with many other haloid compounds, and also with oxyalts, to form numerous double salts. The double salts of the type $\text{HgX}_2 \cdot \text{M}'\text{X}$ and $\text{HgX}_2 \cdot 2\text{M}'\text{X}$ are best regarded as salts of the mercur halogen acids HIIgX_2 and H HgX , respectively, the acids HIIgX_2 have been isolated, and probably also the acids H HgX . The heats of formation of HgX and HgX_2 decrease as the atomic weight of X increases. Thomsen gives the following data (*Z P C* 2, 21) —

X	$[\text{Hg}, \text{X}]$	X	$[\text{Hg}, \text{X}]$
Cl	32,605	Cl	54,490
Br	25,475	Br	41,880
I	15,550	I	25,640

An iodochloride HgICl , and an iodobromide HgIBr , have been isolated.

Mercury, hydrated oxide of. According to Carnelley & Walker (*C J* 53, 80), the hydrate $\text{HgO} \cdot \text{H}_2\text{O}$ is obtained by ppg $\text{HgCl}_2 \cdot \text{Aq}$ by NaOH Aq , and drying in air, it is stable to about 100° , and is completely dehydrated at $c\ 175^\circ$. According to Schaffner (*A* 51, 181) the yellow pp formed by adding KOH Aq to solution of a

mercuric salt is $\text{HgO} \cdot 3\text{H}_2\text{O}$ (*v. Mercuric oxide*, p 222). But according to Millon (*B J* 27, 112), Marchand (*J pr* 37, 277), Rammelsberg (*J pr* [2] 38, 559), and Wallace (*Chem Gazette*, 1858 345), the pp obtained from Hg salts by KOH Aq is HgO .

Mercury, iodides of. Besides the iodides HgI and HgI_2 , corresponding with the chlorides, bromides, and fluorides, of Hg , there is said to exist a definite mercurio mercurio iodide, HgI HgI_2 , and a hexa iodide HgI_6 . Hg and I combine directly with production of heat.

Mercurous iodide HgI or Hg_2I_2 . Mol w not known with certainty. Melts at $c\ 290^\circ$ (with partial decomposition according to Stroman, *B* 20, 2818). Boils at $c\ 310^\circ$ with partial decomposition (Yvon, *C R* 76, 1607). *SG* 7.75 (Boullay, *A Ch* [2] 43, 266). *SH* $17^\circ-99^\circ$ 03949 (Regnault, *A Ch* [3] 1, 129). Crystallises in tetragonal forms, $a = 1.6726$ (Des Cloizeaux, *C R* 84, 1418). *H F* $[\text{Hg}, \text{I}] = 15,550$ (Thomsen, *Z P C* 2, 21).

Formation —1 By rubbing together Hg and I , in the ratio $\text{Hg} : \text{I}$, moistened with a few drops of alcohol, and removing the small quantity of HgI , which is always formed by treatment with alcohol, in which HgI is soluble but HgI_2 is insoluble —2 By rubbing together HgI and Hg in the ratio $\text{HgI} : \text{Hg}$, and dissolving out unchanged HgI by alcohol —3 By heating 10 parts I with $1\frac{1}{2}$ parts Hg in a retort, on a sand bath, to not above 200° , HgI sublimes in red crystals, becoming yellow when cold (Yvon, *C R* 76, 1607). 4 By adding KIAq to solution of a mercuric salt, preferably the acetate (*v. Lefort, Ph* [3] 3, 823).

Preparation —A conc solution of HgNO_3 , containing a little HNO_3 , and free from basic nitrate, is heated to boiling with excess of I , when the I is partially dissolved the liquid is carefully decanted into a warm basin, on cooling, very lustrous transparent, yellow tablets of HgI separate. The crystals are brought on to a filter (best in the dark), washed with cold water containing a little HNO_3 , and then with pure cold water, and dried in the dark at ordinary summer temperature by placing them on filter paper which is frequently changed (Stroman, *B* 20, 2819). HgI is obtained as a flocculent pp by rapidly adding a fairly conc solution of I in alcohol to cold conc $\text{HgNO}_3 \cdot \text{Aq}$ (*S, lc*).

Properties and Reactions — HgI crystallises in yellow tetragonal tablets, isomorphous with HgCl . HgI is sometimes described as a green powder. Stroman (*lc*) says that green preparations are impure. When heated, the yellow crystals become dark yellow, then orange, and finally garnet red. Yvon (*C R* 76, 1607) says that the change of colour begins at 70° , and assigns a definite temperature for each change of colour. Stroman (*B* 20, 2818) could not connect the different colours with definite intervals of temperature, he says that the salt prepared by him was pure yellow at 100° . Sublimation begins at $c\ 190^\circ$ according to Yvon, at $c\ 110^\circ-120^\circ$ according to Stroman. HgI when moist is rapidly blackened by light. HgI is very slightly soluble in water, insoluble in alcohol. It is easily decomposed to Hg and HgI_2 , eg by HIAq , KIAq , and similar iodides. Heated rapidly HgI gives a sublimate of Hg and HgI HgI , HgI

is used in medicine. For medicinal purposes it must be quite free from HgI_2 , which is a violent poison.

MERCURIO MERCURIO IODIDE HgI HgI_2 . A compound of Hg and I of this composition was obtained by Boullay (*A Ch* [2] 34, 345) by adding KIAq containing I, in the ratio $\text{KI} \frac{1}{2} \text{I}$, to HgNO_3Aq . The same compound is said to be obtained by adding KIAq to HgNO_3Aq and digesting the pp for some time in the liquid, also by rubbing together HgI_2 and I in the ratio $3\text{HgI}_2, \text{Hg}$. Mercurio mercurio iodide is described as a yellow powder, insol water and alcohol, unchanged in the dark, but becoming dark when exposed to light. When heated, it turns red, then melts, and may be sublimed unchanged, yielding crystals which are red when hot but become yellow on cooling. HIAq , and various iodides in solution, dissolve HgI_2 , leaving HgI , and then decompose the HgI with separation of Hg.

MERCURIO IODIDE HgI_2 . Mol w 452.86 [238°] (Carnelley & Williams, *C J* 33, 283) (339°–359°) (*C a W, l c*). SG red variety 6.2941 to 6.3004 at 0°, 6.276 at 126°, yellow variety 6.225 at 126° (Rodwell & Elder, *Pr* 28, 284), 6.179 at 200° solid, 5.286 at 200° molten (*R a E, l c*). VD 225.7 to 234.4 (Mitscherlich, *P* 29, 193). SH 18°–99° 0.4197 (Regnault, *A Ch* [3] 1, 129). Crystallises in tetragonal forms (red), $a, c = 1.19955$, also in rhombic forms (yellow), $p, p = 114^\circ 30'$. HF [HgI_2] = 25,640 (Thomsen, *Z P C* 2, 21). Change of yellow to red crystals is accompanied by production of heat, 3000 gram units (Berthelot, *Bl* [2] 39, 17, cf Weber, *P* 100, 127). S 0.04 at 17.5°, 0.05 at 22°, S 286.50 p.c. alcohol at 18°, 1.186 absolute alcohol at 18° (Bourgoin, *Bl* [2] 42, 620).

Formation—1 By the action of I on Hg, Dublanc (*Ph C* 1849 656) says that pure HgI_2 is obtained by pouring 1,000 pts alcohol (93 p.c.) on to 100 pts Hg, and adding 124 pts I in portions of 10 pts at a time, after each addition of I, the whole is agitated until the alcohol becomes colourless, the addition of the last portion of I should leave the alcohol coloured, the HgI_2 is washed with alcohol—2 By adding KIAq or FeI_2Aq to HgCl_2Aq .

Preparation—1 8 pts HgCl_2 and 10 pts KI are dissolved, separately, in water, the solutions are mixed, and the pp is thoroughly washed with cold water. Any excess of KI dissolves some HgI_2 , and any excess of HgCl_2 produces a yellowish pp containing more or less HgCl_2 . Williams (*Ph* [3] 3, 1015) dissolves 8 pts HgCl_2 in 4 pts NH_4Cl in water, and then adds 10 pts KI in water—2 10 pts I are suspended in water, and Fe filings are added until all the I is changed to FeI_2 , the solution is at once added to a solution of 10½ pts HgCl_2 in water, the pp of HgI_2 is rapidly separated from the liquid (to prevent formation of Fe oxychlorides) and washed with cold water. By crystallising from hot KIAq , or, better, from hot conc HClAq (Köhler, *B* 12, 608), HgI_2 is obtained in very lustrous, red tetragonal prisms, with a greenish reflection.

Properties— HgI_2 obtained by ppn is a pure scarlet coloured, crystalline, heavy powder. It is sol. water, S = 66 (Wurtz). Sol hot alcohol; somewhat sol glycerin (in 340 pts, Fairley,

M. S [3] 9, 685); also in ether, and some oils. Sol KIAq , also in conc hot HClAq , from these solutions HgI_2 separates in well formed crystals. HgI_2 is dimorphous. Red (tetragonal) HgI_2 is changed to the yellow (rhombic) modification by heat, the change occurs at 126° (Rodwell & Elder, *Pr* 28, 284), it is accompanied by a sudden, and then by a regular, expansion. SG, red at 126° = 6.276, yellow at 126° = 6.225 (*R a E*). HgI_2 melts at 238° (Carnelley & Williams, *C J* 33, 283), at 253°–254° according to Köhler (*B* 12, 608), to a blood red liquid, melting is attended with considerable expansion. At c 339°–359° the liquid boils, and sublimes to yellow rhombic plates. The yellow variety passes into the red at the ordinary temperature, this change is hastened by rubbing or scratching the red crystals, heat is produced in the process, 3,000 gram units according to Berthelot (cf Weber, *P* 100, 127). The HgI_2 obtained by adding cold KIAq to cold HgCl_2Aq appears at first yellow, but it quickly changes to red, the change of crystalline form in this case may be observed under the microscope. Solutions of HgI_2 in alcohol, ether, or KIAq are colourless, if the HgI_2 is allowed to form slowly from these solutions, the crystals are red, but if the ppn is made rapid, e.g. by pouring an alcoholic solution into water, the crystals appear yellow for a moment, but they quickly change to red (cf Schiff, *A* 111, 371, Selmi, *J* 1855 417).

Reactions—1 HgI_2 dissolves in *hydriodic acid* solution with production of heat (v Berthelot, *Bl* 38, 369). This solution has about the same heat of neutralisation as HIAq (Thomson), with alkalis it forms salts HgI_2MI , the solution very probably contains the acid H_2HgI_2 (cf *Combinations*, No 2). An *iodomercuric acid*, HHgI_2 , has been obtained by slightly warming excess of HgI_2 with HIAq , filtering through asbestos, and cooling to between 0° and –4° (Neumann, *M* 10, 236), this acid is very readily decomposed by moisture and by heat. According to Boullay (*A Ch* [2] 34, 345) a solution of HgI_2 in hot HIAq deposits I on cooling, and then crystals of $2\text{HgI}_2, 3\text{HI}$ —2 Most heavy metals, e.g. Zn, Sn, when triturated with HgI_2 , remove I and leave Hg, *potassium* acts in the same way—3 HgI_2Aq is decomposed by alkalis, with separation of HgO and formation in solution of a double salt $x\text{HgI}_2, y\text{MI}$. *Baryta* and *strontia* react similarly to alkalis—4 *Lime*, *sodium carbonate*, and *potassium carbonate* do not decompose HgI_2Aq , but a solution of HgI_2 in alcohol is decomposed by these reagents—5 HgI_2 dissolves in hot *calcium hypochlorite* solution, on cooling Ca periodate is deposited and HgCl_2 remains in solution (Rammelsberg). 6 When HgI_2 is boiled with *nitric acid*, S HgI_2 1.5–1.4, $\text{Hg}(\text{IO}_3)_2$ is formed, with acid SG 1.3, white leaflets of $\text{HgI}_2, \text{Hg}(\text{NO}_3)_2$ separate, with acid SG 1.2, crystals of unchanged HgI_2 are obtained, together with some of the compound $\text{HgI}_2, \text{Hg}(\text{NO}_3)_2$ (Kraut, *Z* 18, 3461)—7 *Chlorine*, passed into water containing HgI_2 in suspension, produces a yellow solution containing HgCl_2 and ICl_2 (Fehlbol).

Combinations—1 With *hydriodic acid* (v *Reactions*, No 1)—2 With various metallic iodides to form double salts, regarded by Von Bonsdorff as *iodomercurates* (*P* 17, 265).

These salts have been examined chiefly by Boullay (*A Ch* [2] 34, 345). They are generally obtained by dissolving HgI_2 in a solution of the other iodide and evaporating. The following are the most important -

(i) With *alkali iodides* (a) With *potassium iodide* $2HgI_2 \cdot 2KI \cdot 3H_2O$, $HgI_2 \cdot 2KI$. The former is produced by saturating boiling $KIAq$ with HgI_2 , filtering, separating from HgI_2 , which crystallises out, and evaporating. Sol. alcohol and ether. Decomposed by water, with formation of HgI_2 , and $HgI_2 \cdot 2KI$ which separates on evaporation. These soluble salts may be prepared by boiling $KIAq$ with HgO , the solution contains the double salts and also KOH (*cf Jahn, Ar Ph* [3] 1, 97). (b) With *sodium iodide* $NaIAq$ reacts with HgI_2 similarly to $KIAq$, the compositions of the double salts of NaI with HgI_2 have not been satisfactorily determined. (c) With *ammonium iodide* $2(NH_4I \cdot HgI_2) \cdot 3H_2O$, obtained, as yellow needles, by dissolving HgI_2 in hot NH_4IAq , separating from HgI_2 , which forms on cooling, and evaporating.

(ii) With *other metallic iodides* BaI_2 , SrI_2 , CaI_2 , and MgI_2 solutions react with HgI_2 similarly to $KIAq$, the double salts are probably $M_2 \cdot HgI_2$. HgI_2 appears to form double compounds with CdI_2 and Kel . The compound $2HgI_2 \cdot CuI_2$ was obtained by Hess (*D P J* 218, 183) - 3 HgI_2 combines with *mercuric chloride*, also with *mercuric bromide* (*v Mercury, iodochlorides and iodobromides of, infra*) - 4 Combines with *mercuric sulphide* (*v Mercuric sulphide, Combinations*, No 5, p 225).

MERCURY, HEXA IODIDE OF HgI_2 . This periodide is said by Jørgensen (*J pr* [2] 2, 357) to be obtained by adding cold $HgCl_2$ Aq , followed by addition of water, to an alcoholic solution of KI , heated to 50° . If the solutions are mixed hot, large rhombic crystals of HgI_2 are formed, but they are always mixed with HgI_2 . HgI_2 is decomposed quickly by alcohol, slowly by water, with formation of red HgI_2 . HgI_2 possesses most of the optical properties of *tourmalin*.

Mercury, iodobromide of $HgIBr$. Sulphur yellow, translucent, rhombic prisms, $a b c = 0.443 \ 1 \ 0.9194$ (Groth, *B* 2, 574). Melts at $c \ 229^\circ$, and boils at $c \ 360^\circ$, crystallisable from ether, may be sublimed unchanged. Produced by crystallising a mixture of HgI_2 and $HgBr_2$ from ether or acetone, also by the reaction of an alkyl iodide, *e g* EtI , on $HgBr_2$, dissolved in acetone (Oppenheim, *B* 2, 571).

Mercury, iodochlorides of Two iodochlorides of Hg have been isolated. (i) $HgI_2 \cdot 2HgCl_2$ ($=Hg_3I_2Cl_4$). Obtained by dissolving HgI_2 in hot $HgCl_2$, and cooling (Liebig, *S* 49, 252), also by boiling $HgCl_2$ with excess of I and much water until I vapour is no longer given off (Selmi, *J* 1855 417). (ii) $HgICl$. Prepared by heating, in a closed tube at 140° - 160° , HgI_2 , $HgCl_2$, and a little water, until no HgI_2 remains unchanged (Köhler, *B* 12, 1187). Boullay (*P* 48, 175) said that $HgICl$ is produced by saturating hot $HgCl_2$ Aq with HgI_2 , but Köhler found that very little was formed in this way. $HgICl$ forms a citron-yellow crystalline mass, which becomes red after about 12 hours. The red modification forms tetragonal, the yellow forms rhombic, crystals. $HgICl$ is citron-yellow at

$c \ 125^\circ$, it melts at $c \ 158^\circ$ to a golden coloured liquid which solidifies at $c \ 146^\circ$, it is slightly soluble, with partial decomposition, in hot water, more soluble in alcohol. $HgICl$ may be sublimed, with only slight decomposition, in a stream of HCl , SO_2 , or H_2S . From a solution of $HgICl$ in dilute $HClAq$, H_2S ppt's a yellow solid, probably $HgICl \cdot HgS$ (Köhler, *lc*).

Mercury, iodosulphides of, *v Mercuric sulphide, Combinations*, No 5, p 225

Mercury, nitride of Hg_3N_2 (*Trimercuramine*). This compound was first isolated by Plantamour (*A* 40, 115). $Ppd \ HgO$ is dried at 40° - 50° , and then heated at 100° in a stream of dry NH_3 , so long as water is evolved (Hirzel, *J* 1852 419). Plantamour directed to pass NH_3 over cold HgO , then to heat to 150° in NH_3 , and finally to remove unchanged HgO by HNO_3 Aq , Hirzel found that HNO_3 Aq reacts with Hg_3N_2 . Mercury nitride is a brown powder, very explosive, but requires a higher temperature, or a stronger blow, than nitrogen iodide to explode it. Hg_3N_2 is not acted on by cold dilute H_2SO_4 , the hot acid decomposes it. Conc H_2SO_4 reacts energetically and explosively. Conc HNO_3 Aq forms $Hg(NO_3)_2$ and NH_4NO_3 , dilute HNO_3 Aq forms a white powder, $HClAq$ forms $HgCl_2$ and NH_4Cl . Mixed with KOH and heated, NH_3 and Hg are formed. Moist Hg_3N_2 is slowly decomposed by light, in water it is changed, after 24 hours, to a white powder.

Mercury, oxides of. Two oxides of Hg are known, Hg_2O and HgO , it is doubtful whether Hg_2O has been obtained free from Hg and HgO . Neither oxide has been gasified, and the mol w of neither is known with certainty.

MERCUROUS OXIDE Hg_2O (*Suboxide, or black oxide, of mercury*). This oxide is prepared by adding $NaOHAq$ or $KOHAq$ to solution of a mercurous salt, or to $HgCl$ suspended in water. The best salt to use seems to be $HgNO_2$, it should be dissolved in water with a very little HNO_3 , the solution being made dilute, ppn with $KOHAq$, and washing with cold water, should be performed in the dark, and the black pp should be dried in the dark without heating. Guibourt (*A Ch* [2] 1, 422) says that Hg_2O cannot be obtained quite free from Hg and HgO , this is confirmed by Bruns a O v d Flordten (*B* 21, 2010), who assert that Hg_2O oxidises to HgO at the ordinary temperature. Barfoed (*J pr* [2] 38, 441) says that the product of the action of $NaOHAq$ on mercurous salts is a mixture of Hg_2O , HgO , and Hg in varying proportions. The descriptions of Hg_2O probably apply to Hg_2O mixed with more or less Hg and some HgO .

Mercurous oxide is a black powder, *S G* 10 69 (Herapath, *P M* 64, 321), 8 95 (Karsten, *S* 65, 894). $H.F [Hg_2O] = 24,860$ (Thomsen, *Z P C* 2, 21). Hg_2O is decomposed very easily by light or heat, giving HgO and Hg , strongly heated gives Hg and O . Dilute $HClAq$ produces $HgCl$. Hg_2O is soluble in conc acetic acid. With dilute acids Hg_2O generally yields mercurous salts, with H_3PO_4 Aq it gives H_3PO_4 and Hg . Boiled with $KIAq$, Hg and $HgI_2 \cdot 2KIAq$ are formed (Berthelot, *J Ph* 14, 189). With conc. NH_4OHAq , NH_3 is evolved and Hg and $HgCl_2$ are produced (Pagenstecher, *R. P.* 27, 27, Thompson, *P. M* [3] 10, 179).

MERCURIC OXIDE HgO . (*Red oxide of mercury* *Red precipitate*) Mol w unknown, as compound has not been gasified SG 11 074 at 17.5° (Herapath, *P M* 64, 321), 11 136 to 11 344 at 4° (Playfair a Joule, *C S Mem* 3, 84, and *C J* 1, 137), 11 29 at 4° *in vacuo* (Le Royer a Dumas, in Bottger's *Tabellarische Uebersicht der Spec Gewichte der Körper*, Frankfurt, 1837) $S H$ $19^\circ-52^\circ = 053$ (Kopp, *T* 155, 71), $5^\circ-98^\circ = 0518$ (Regnault, *A Ch* [3] 1, 129) $H F$ (Hg_2O) = 22,000 (Thomsen, *Z P C* 2, 21) Crystallises in rhombic forms $a b c = 6523$ 1 9456 (Nordenskjöld, *P* 114, 621), in monoclinic forms, according to Des Cloiseaux (*A Ch* [4] 20, 201) $C E$ ($0^\circ-100^\circ$) 0058 (Playfair a Joule, *C J* 1, 137)

HgO was known to the Arabians in the eighth century, Geber prepared it by calcining the nitrate, and towards the end of the seventeenth century Boyle obtained it by strongly heating Hg in air

Formation—By heating Hg to near its B P in a loosely covered vessel for a long time

Preparation—1 Hg is dissolved in HNO_3Aq , the solution is evaporated to dryness, the residue is powdered and then heated on a sand tray so long as N oxides are evolved, the temperature being slowly raised, and the heating continued till a porcelain plate held over the vessel shows a slight deposit of Hg HgO thus prepared forms red lustrous scales—2 One of the oxychlorides 2HgO HgCl_2 , and the oxychloride 4HgO HgCl_2 , when treated with KOH Aq , give red HgO , another oxychloride 2HgO HgCl_2 , and also the oxychloride 3HgO HgCl_2 , give yellow HgO by treatment with KOH Aq The compound 2HgO HgCl_2 which yields red HgO is prepared by mixing 1 vol KHCO_3Aq , free from K_2CO_3 , saturated at 15° , with 3 vols HgCl_2Aq , also saturated at 15° , stirring with a glass rod till black streaks appear where the rod rubs the glass, pouring off, adding a fresh quantity of the mixed solution, and again stirring The compound 2HgO HgCl_2 which gives the yellow HgO is prepared by stirring a mixture of 1 vol KHCO_3Aq , saturated at 15° , with 6 to 10 vols HgCl_2Aq , also saturated at 15° The compound 4HgO HgCl_2 is prepared by mixing 1 vol HgCl_2Aq (saturated at 15°) with a large excess (4 to 6 vols) KHCO_3Aq (saturated at 15°), and allowing to stand for some time (*cf Mercury, oxychlorides of*, p. 223)—3 $\text{Hg}(\text{NO}_3)_2\text{Aq}$, or HgCl_2Aq , is poured into KOH Aq , the pp is thoroughly washed and dried at $100^\circ-120^\circ$ HgO thus prepared forms a yellow compact solid

Properties.— HgO exhibits allotropy, it forms heavy, red, crystalline scales, or a somewhat more bulky, amorphous, yellow powder (*vsupra*) HgO is a violent irritant poison HgO is very slightly soluble in water, 1 pt dissolves in 200,000 cold water, or in 125,000 pts if the water is boiled with HgO and then allowed to cool (Wallace, *Chem Gazette*, 1858, 845) The solution has a metallic taste Heated to redness, Hg is separated into Hg and O Heated below the temperature of decomposition, HgO turns black, but recovers its original colour on cooling. HgO is slowly blackened and decomposed to Hg and O by the action of light There are differences in the reactions of Cl , HgCl_2 , in

alcoholic solution, and oxalic acid, with the two varieties of HgO (*v Reactions*, Nos 8, 9, 10)

Reactions—1 Decomposed by heating to redness, giving Hg and O , Pelouze (*C R* 16, 50) said that yellow HgO is decomposed at a lower temperature than the red variety, but this was not confirmed by Gay Lussac (*C R* 16, 309), nor by Millon (*B J* 27, 112) Carnelleys Walker (*C J* 53, 80) found that HgO , ppd by NaOH Aq from HgCl_2Aq , began to give off O at a little above 175° , and that evolution of O became rapid at $c 415^\circ$, at which temperature red HgO was formed and decomposed Myers's results (obtained by measuring vapour pressures of O from HgO , *B* 6, 11) agree with those of *C* a W Debray (*C R* 77, 123) found that when a tube containing HgO was sealed, and the whole tube was heated to 440° , the O evolved was almost wholly again absorbed—2 A mixture of HgO with such easily oxidised bodies as *P*, *S*, *Sb*, detonates when heated more or less violently Some organic compounds are oxidised by boiling in solution with HgO SO_2Aq boiled with HgO produces SO_3Aq and Hg SnCl_2Aq forms SnCl_2Aq and Hg —3 HgO is decomposed, rapidly and somewhat violently, by heating with *magnesium*, in the ratio HgO Mg , with formation of MgO and Hg (Winkler, *B* 23, 128)—4 Heated with *sodium*, *Na* amalgam and the compound $\text{Na}_2\text{O HgO}$ are formed (Bickeloff, *B* 13, 2392), the compound $\text{Na}_2\text{O HgO}$ is not decomposed by heat, but very quickly by water—5 HgO dissolves in *molten potash* If the KOH is nearly saturated with HgO , allowed to cool slowly, and lixiviated with a little cold water, a heavy violet crystalline powder and a lighter greyish green powder are obtained The violet powder is said to consist of $\text{K}_2\text{O HgO}$, and the greyish powder to contain from 2 to 5 p.c. K_2O , the SG of $\text{K}_2\text{O HgO}$ is 10.31, it is decomposed at high temperatures, also by continued washing with water, but less completely by alcohol (St Meunier, *C R* 60, 557)—6 According to Foubert (*A Ch* [4] 1, 300), saturated solutions of the *alkali and alkaline earth haloid compounds* are decomposed, with separation of alkali or alkaline oxides, by boiling with HgO (*cf* Melsens, *A Ch* [3] 26, 220, and *H Rose*, *P* 107, 298) André, however, says that boiling saturated solutions of alkaline earth chlorides react with HgO to form either oxychlorides $x\text{HgCl}_2$, $y\text{HgO}$, or compounds of HgO with the alkaline chloride (*C R* 104, 431, *v Mercury oxychlorides of*, p. 223, and also *infra*, *Combinations*, No 1) According to Jehn (*Ar Ph* [3] 1, 97), HgO boiled with KI Aq produces KOH Aq and the double iodide HgI_2KI —7 HgO reacts with most acids to form mercuric salts HgX_2 ($\text{X} = \text{NO}_3$, $\frac{1}{2}\text{SO}_4$, $\frac{1}{2}\text{PO}_4$, &c)—8 The reaction of *chlorine* with HgO differs according to the conditions, and the variety of HgO used Cl scarcely reacts with red crystalline HgO , with yellow HgO , prepared by ppn and dried at $c 100^\circ$, Cl reacts energetically forming HgCl_2 and O , with the yellow oxide, dried at 300° and cooled, Cl reacts more slowly, forming Cl_2O and HgCl_2 , or, if water be present, forming HgClO Aq and HgO HgCl_2 (*cf vol* i pp 12, 16)—9 An alcoholic solution of *mercurous chloride* heated with yellow HgO at once produces black oxychloride HgO HgCl_2 , the same oxychloride is formed from the red variety of

HgO only after prolonged action of boiling alcoholic HgCl_2 solution—10 *Oxalic acid solution* reacts with yellow HgO, to form oxalate, in the cold, but the red variety is unchanged when boiled with $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$

Combinations — 1 With *alkaline earth chlorides*, obtained by the reaction of HgO with solutions of CaCl_2 , BaCl_2 , and SrCl_2 . The compounds $2\text{HgO} \cdot \text{CaCl}_2 \cdot 4\text{H}_2\text{O}$, $\text{HgO} \cdot \text{BaCl}_2 \cdot 6\text{H}_2\text{O}$, and $\text{HgO} \cdot \text{SrCl}_2 \cdot 6\text{H}_2\text{O}$, are described by André (*C R* 104, 431)—2 With *ammonia*, to form $2\text{HgO} \cdot \text{NH}_3 \cdot \text{H}_2\text{O} = \text{NH}_4\text{OH} \cdot 2\text{HgO}$, this compound reacts with acids as a base forming *ammonium salts* (v *MERCURAM MONIUM COMPOUNDS*, p 206)

Mercury, oxybromide of $8\text{HgO} \cdot \text{HgBr}_2 = \text{Hg}_9\text{O}_8\text{Br}_2$ (*Basic mercuric bromide*) A yellow, crystalline, powder, obtained by boiling HgBr_2Aq with HgO, filtering, and allowing to crystallise, or by partial ppn of HgBr_2Aq by KOHAq, and boiling the liquid in contact with the pp (Lowig, *P* 14, 485, cf Rammelsberg, *P* 55, 248)

For H F of oxybromides of Hg v André, *Bl* [2] 41, 274

Mercury, oxychlorides of $\text{Hg}_2\text{O}_2\text{Cl}_2$ (*Basic mercury chlorides*) Several oxychlorides of Hg are known, they are produced by the reaction of HgO with HgCl_2Aq , by partial ppn of HgCl_2Aq by KOHAq or NaOHAq, by mixing KHCO_3Aq and HgCl_2Aq in different proportions, and by the reaction of Cl with yellow HgO

Millon (*A Ch* [3] 27, 253) described oxychlorides obtained by mixing solutions of KHCO_3 (free from K_2CO_3) and HgCl_2 , both saturated at 15° (i) $2\text{HgO} \cdot \text{HgCl}_2$, by adding 1 vol KHCO_3Aq to 6–10 vols HgCl_2Aq , also by adding 1 vol KHCO_3Aq to 3 vols HgCl_2Aq , stirring till ppn begins on the sides of the vessel, pouring off the liquid, adding a fresh quantity of the same mixture, and stirring again. The compound obtained by the first process forms a red non crystalline powder, and yields *yellow* HgO when acted on by KOHAq, as obtained by the second process, the compound is a heavy, black, lustrous solid, which yields *red* HgO with KOHAq (ii) $3\text{HgO} \cdot \text{HgCl}_2$, by mixing equal volumes of the solutions of KHCO_3 and HgCl_2 , and allowing to stand, a golden yellow crystalline pp, yielding *yellow* HgO with KOHAq (iii) $4\text{HgO} \cdot \text{HgCl}_2$, by mixing 1 vol HgCl_2Aq with 4–6 vols KHCO_3Aq , and allowing to stand, a brown crystalline solid, which yields *red* HgO with KOHAq

Roucher (*A Ch* [3] 18, 372) described seven oxychlorides, containing HgCl_2 and HgO in the ratios 1, 2, 3, 4, 5, and 6, each oxychloride exists, according to Roucher, in two varieties, one derived from and giving *red* HgO, the other derived from and giving *yellow* HgO, some of the oxychlorides also exhibit other differences. Roucher described 15 different oxychlorides. A tabular statement showing the chief differences between the oxychlorides is given by Roucher

André (*C R* 104, 431) described two oxychlorides, $\text{HgCl}_2 \cdot 3\text{HgO}$ and $2\text{HgCl}_2 \cdot 8\text{HgO}$, obtained by dissolving HgO in boiling CaCl_2Aq and MgCl_2Aq , respectively, and pouring the solutions into large quantities of cold water.

The oxychlorides of Hg have been examined more recently by Thümmel (*Ar. Ph.* 37, 589, v.

abstract in *C J* 56, 1050) f. says that only 5 definite compounds exist, viz, $\text{HgO} \cdot 2\text{HgCl}_2$, $\text{HgO} \cdot \text{HgCl}_2$, $2\text{HgO} \cdot \text{HgCl}_2$, $3\text{HgO} \cdot \text{HgCl}_2$, and $4\text{HgO} \cdot \text{HgCl}_2$. (i) $\text{HgO} \cdot 2\text{HgCl}_2$ is formed in all solutions prepared by dissolving HgO in HgCl_2Aq , but it is readily decomposed, it is best prepared by heating at 100° 1 pt HgO (red or yellow), with 10 pts HgCl_2 , and 60 pts water, stirring till no further separation of a yellow powder occurs, washing, drying, and then washing with ether (free from alcohol) to remove HgCl_2 . Warm water separates $2\text{HgO} \cdot \text{HgCl}_2$, NaOHAq ppts *red* HgO. (ii) $\text{HgO} \cdot \text{HgCl}_2$ has not yet been obtained pure. (iii) $2\text{HgO} \cdot \text{HgCl}_2$ exists in two varieties, (a) *red* variety, obtained by mixing solutions of NaHCO_3 and HgCl_2 in the ratio 2NaHCO_3 , HgCl_2 , (b) *black* variety, obtained by heating the red variety when dry, or by adding HgO to hot HgCl_2Aq , or by mixing equivalent quantities of *red* HgO and HgCl_2 in cold water, or by treating $3\text{HgO} \cdot \text{HgCl}_2$ with cold HgCl_2Aq . (iv) $3\text{HgO} \cdot \text{HgCl}_2$ is a yellow pp obtained by adding alkaline carbonate (normal or acid) to HgCl_2Aq , avoiding excess of the carbonate, also by treating freshly ppd *yellow* HgO with HgCl_2Aq (this preparation is yellow and yields *yellow* HgO with KOHAq), also by treating washed *red* HgO with HgCl_2Aq (this preparation is reddish yellow and yields *red* HgO by KOHAq). (v) $4\text{HgO} \cdot \text{HgCl}_2$ is obtained as a brown amorphous powder, by adding KHCO_3Aq to HgCl_2Aq , in the ratio 30 to 35 KHCO_3 , HgCl_2 , it is also obtained, as reddish-brown crystalline plates, by shaking HgCl_2Aq with *red* HgO in the ratio HgCl_2 , 6HgO , both varieties give *yellow* HgO by KOHAq. All these oxychlorides yield sublimates containing HgCl and HgCl when heated

For H F of oxychlorides of Hg v André, *Bl* [2] 41, 274

Mercury, oxycyanides of, v. CYANIDES, vol. ii p 342

Mercury, oxyfluoride of $\text{HgO} \cdot \text{HgF}_2 \cdot \text{H}_2\text{O}$ (*Basic mercuric fluoride*) A yellow crystalline solid, obtained by dissolving freshly ppd HgO in HFAq , and digesting the solution with HgO, or evaporating the solution (Finkener, *P* 110, 628). The oxyfluoride is also obtained by heating $\text{HgF}_2 \cdot 2\text{H}_2\text{O}$ (*q v* p 210) to 30° (*F*). Heated above 100° , the oxyfluoride gives off H_2O and HF, it is decomposed by water with separation of HgO

Mercury, oxyiodide of $3\text{HgO} \cdot \text{HgI}_2$ (*Basic mercuric iodide*) A yellowish brown solid, obtained by melting together HgO and HgI_2 in the ratio $3\text{HgO} \cdot \text{HgI}_2$, also by digesting HgI_2 with dilute KOHAq (Rammelsberg, *P* 48, 182)

Mercury, oxysulphides of Oxysulphides of Hg have been described, but according to Pollock (*B* 22, 2859) none has been isolated, and the existence of any is very improbable

Mercury, phosphide of No phosphide of Hg has been isolated with certainty. By passing P hydride, prepared by boiling amorphous P with KOHAq, into HgCl_2Aq , several compounds have been obtained. Aschan (*Chem. Zeitung*, 10, 82, 102) describes a yellow compound $3\text{Hg}_2\text{P}_2 \cdot 7\text{HgCl}_2$, a red compound $4\text{Hg}_2\text{P}_2 \cdot 5\text{HgCl}_2$, and a black compound $\text{Hg}_2\text{P}_2 \cdot \text{HgCl}_2$. A compound probably $2\text{PH}_3 \cdot 6\text{HgO}$ is said by Aschan (*lc*) to be formed by passing P hydride over Hg_2CO_3 . The ppn.

formed when P hydride is passed into $\text{Hg}(\text{NO}_3)_2\text{Aq}$ are probably mixtures of different compounds of Hg, P, and HNO_3 . (A) Most of the foregoing compounds are readily decomposed, some explosively, by warming.

Mercury, salts of Hg forms two series of salts, *mercurous salts* corresponding with Hg_2O , and *mercuric salts* corresponding with HgO . The former are obtained sometimes by dissolving Hg_2O in acids, sometimes by dissolving Hg in acids and digesting with excess of Hg, and in some cases by double decomposition from the nitrate, the mercuric salts are obtained by dissolving HgO or HgCO_3 in acids, or by double decomposition from the nitrate. The mercurous salts have the composition Hg_2X , where $\text{X} = \text{NO}_3$, $\frac{1}{2}\text{SO}_4$, &c., the mercuric salts have the composition HgX_2 . The mercuric salts are more stable, as a class, than the mercurous salts. The normal mercurous salts are generally decomposed by water into a basic salt, which separates, and an acid salt, which goes into solution. Many basic salts and a large number of double salts are known. The salts of Hg, as a class, act as violent and irritating poisons. The principal salts of Hg are the following (*v* CARBONATES, NITRATES, SULPHATES, &c.) *antimonates, arsenates and -ites, bromates, carbonates, chlorates and perchlorates, chromates, iodates and periodates, molybdates, nitrates and -ites, phosphates, selenates and -ites, sulphates and -ites, tantalates, thiosulphates, tungstates, vanadates*.

Mercury, selenide of HgSe Small quantities of more or less pure HgSe occur native in the Harz, accompanying PbSe . HgSe is produced by strongly heating together Hg and Se, and subliming at a higher temperature, forms grey, metal like, lustrous laminae, dissolved by *aqua regia* with formation of Hg selenite, slowly changed to the same compound by boiling conc nitric acid (Uelsmann, *A* 116, 126, cf Little, *A* 112, 211). HgSe is also formed by passing H_2Se for a long time into HgCl_2Aq , the white pp of $2\text{HgSe} \cdot \text{HgCl}_2$ at first produced is changed to black HgSe . S G of natural HgSe is 7.1 to 7.4, S G of artificially prepared HgSe is 8.77.

Combinations—1 With *mercuric chloride*, to form $2\text{HgSe} \cdot \text{HgCl}_2$, a white pp formed by adding H_2Se , or K_2Se , to excess of HgCl_2Aq .—2 With *mercuric oxide*, to form $2\text{HgSe} \cdot \text{HgO}$, a black powder formed by treating $2\text{HgSe} \cdot \text{HgCl}_2$ with NaOH Aq . Decomposed by heat, yielding sublimates of HgSe and Hg (Uelsmann, *A* 116, 126).

Mercury, selenochloride of $\text{Hg}_2\text{Se}_2\text{Cl}_4$, *v* *Mercury, selenide of, Combinations*, No 1.

Mercury, selenosulphide of A mineral approaching the composition $\text{HgSe} \cdot 4\text{HgS}$ is found near San Onofre in Mexico, it is known as *onofrite*.

Mercury, selenocyanides of HgSeCy and $\text{Hg}(\text{SeCy})_2$, *v* vol u p 348.

Mercury, silicofluorides of Two are known, $\text{Hg}_2\text{SiF}_6 \cdot 2\text{H}_2\text{O}$ and $\text{HgSiF}_6 \cdot 6\text{H}_2\text{O}$.

MERCUROUS SILICOFLOURIDE, $\text{Hg}_2\text{SiF}_6 \cdot 2\text{H}_2\text{O}$ Clear prismatic crystals, obtained by dissolving Hg_2CO_3 in $\text{H}_2\text{SiF}_6\text{Aq}$, evaporating, washing with a little water, and pressing between paper (Finkener, *P* 111, 246, cf Berzelius, *P* 1, 200).

MERCURIC SILICOFLOURIDE, $\text{HgSiF}_6 \cdot 6\text{H}_2\text{O}$. Obtained by dissolving HgO in $\text{H}_2\text{SiF}_6\text{Aq}$, evaporating till yellow needles ($\text{HgSiF}_6 \cdot \text{HgO} \cdot 3\text{H}_2\text{O}$) begin to separate, and then allowing to stand at a temperature not above 15° . Forms clear, colourless, rhombohedral crystals, very unstable, deliquescent in air, and efflorescent over H_2SO_4 , composition doubtful (Finkener, *P* 111, 246). The compound $\text{HgSiF}_6 \cdot \text{HgO} \cdot 3\text{H}_2\text{O}$ (Finkener) was described by Berzelius (*P* 1, 200) as the normal salt.

Mercury, sulphides of Two are known, Hg_2S and HgS , the latter reacts towards the alkali sulphides as an acidic sulphide, it also combines with many Hg compounds to form double compounds.

MERCUROUS SULPHIDE, Hg_2S This sulphide is best prepared, according to Berzelius, by dropping mercurous acetate solution into Na or NH_4 sulphide solution (cf Brande, *Q J S* 18, 292). HgNO_3Aq should not be used, as the HNO_3 produced oxidises the Hg_2S . Hg_2S is a black powder, easily decomposed by heat to HgS and Hg. According to Barfoed (*Bl* [2] 3, 183) the substance described as Hg_2S always contains some Hg, however it may be prepared.

MERCURIC SULPHIDE, HgS Mol w uncertain $\text{H F} [\text{Hg}_2\text{S}] = 8.220$ (Thomsen, *Z P C* 2, 21). This compound exists in two forms a black amorphous pp, and a red crystalline body known as *vermilion* or *cinnabar*.

Occurrence—In Illyria, Spain, Bohemia, Ural mountains, China, Japan, Mexico, California, Chili, and Peru.

Formation—1 By rubbing or heating to gether 1 pt S and 6 $\frac{1}{4}$ pts Hg.—2 By adding H_2S , or an alkaline sulphide, to solution of a mercuric salt.—3 By digesting Hg with an alkaline polysulphide.—4 By subliming a mixture of S and HgO or HgSO_4 .

Preparation—1 Amorphous black mercuric sulphide is prepared by passing excess of H_2S into slightly acidified HgCl_2Aq or $\text{Hg}(\text{NO}_3)_2\text{Aq}$, washing the pp thoroughly with dilute HNO_3Aq and then with water, and drying at a low temperature.—2 Red crystalline mercuric sulphide (vermilion) is prepared in different ways (a) A mixture of 6 pts Hg and 1 pt S is heated till combination occurs (attended generally with production of heat and light and partial projection of the mass), the product is powdered, mixed with a small quantity of S, and heated for some hours in a hard glass flask, sunk in sand in a wind-furnace, the flask is loosely closed by a charcoal stopper and is arranged so that the upper part is kept comparatively cold, red HgS sublimes on to the neck of the flask. The HgS is purified by grinding, boiling with KOH Aq , and washing with water. (b) Black amorphous HgS is heated with an alkaline persulphide. This may be done by triturating 100 pts Hg with 38 pts S for some hours, till black HgS is produced, heating with 25 pts KOH in 130–150 pts water to 45° – 50° for several hours (the water being replaced as it evaporates, and the mass being stirred from time to time) until reddening begins, after which the temperature is maintained at 45° till the whole is bright red. The red HgS is washed, and any Hg present is removed by levigation (Brunner, *P* 15, 598, cf Döbereiner, *S* 61, 860;

Firmenich, *D P J* 172, 370, Liebig, *A* 5, 289, 7, 49, Raab, *N R P* 24, 39) (HgCl_2Aq is poured into excess of dilute NH_4Aq , to the pp of NH_4HgCl thus produced is added conc $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ in quantity rather more than sufficient to dissolve the pp, and the whole is heated for some time to $70^\circ\text{--}80^\circ$ (Hausmann, *B* 7, 1746) For details of the manufacture of *Vermilon v* DICTIONARY OF APPLIED CHEMISTRY—8 Colloidal mercuric sulphide, soluble in water, is obtained by ppg a dilute solution of a mercuric salt by H_2S , and washing with water or dilute H_2SAq for a long time (Winssinger, *Bl* [2] 49, 452)

Properties—The black sulphide is an amorphous, heavy powder, heated in a closed vessel, it yields a sublimate of red HgS , heated in air, Hg sublimes and SO_2 is formed, it is not acted on by dilute acids The red sulphide crystallises in hexagonal forms, $a=c=1.145$, S_G 8.1 to 8.99, polarises light, blackens by exposure to light (*v* Heumann, *B* 7, 750), heated to the sublimation temperature, red HgS is changed to the black variety (Fuchs, *P* 31, 581) Mitscherlich (*A* 12, 168) found V D of HgS at 670° to be 85.3, V and C Meyer found V D at 1660° to be 78, the formula HgS requires V D 116, a mixture of $\text{Hg} + \text{Hg} + 2\text{S}$ requires V D 77.3 The red sulphide reacts with acids more slowly than the black variety The colloidal sulphide is soluble in water, forming a solution which is black and opaque when conc, but brown, with a greenish tint by reflected light, when dilute, a very dilute solution may be boiled till all H_2S is expelled, or kept for some time, without change

Reactions—1 Heated in a closed vessel, HgS sublimes—2 Heated in air, SO_2 is formed, and Hg sublimes—3 Heated with solid alkalis or alkaline carbonates, Hg sublimes and alkaline sulphide remains—4 Heated with iron, tin, antimony, copper, zinc (and some other metals), a metallic sulphide and Hg are produced, HgS is decomposed by heating with finely divided Cu and water (*v* Heumann, *B* 7, 1388, 1486)—5 Digested for some time with iodine in KIAq , HgS is decomposed with formation of HgI_2 2KI and separation of S (Wagner, *J pr* 98, 23)—6 HgS is decomposed to Hg and SO_2 by heating with lead monoxide, Pb being separated.—7 HgS is scarcely attacked by dilute acids, conc nitric acid produces $\text{Hg}(\text{NO}_3)_2$ mixed with HgSO_4 , HNO_3Aq S G c 1.2 produces a white compound $2\text{HgS} \cdot \text{Hg}(\text{NO}_3)_2$.—8 According to Bolley (*A* 75, 239) HgS is at once decomposed by an ammoniacal solution of silver nitrate, with formation of a mercurammonium salt and Ag_2S —9 HgS is insoluble in caustic soda or sodium monosulphide solution, but it dissolves in a mixture of the two, i.e. in sodium hydrosulphide solution This solution contains a sulpho-salt (sulphohydrargyrate of sodium) The solution is readily obtained by adding KOHAq to ppd HgS , and passing in H_2S (excess of H_2S causes reppn of HgS) On evaporation, white crystals $\text{HgS} \cdot \text{K}_2\text{S} \cdot 5\text{H}_2\text{O}$ separate, mixed with KOH , these crystals are decomposed by water (Weber, *P* 97, 76, *cf* Brunner, *P* 15, 596) By ppg HgCl_2Aq with NH_4S sulphide, and adding KOHAq , a solution is obtained, which, on evaporation, yields KCl , and then a sulpho-salt mixed with KOH .

VOL. III.

According to Schneider (*P* 127, 488) the crystals of the sulpho-salt, when kept for some years in KOHAq , form six sided, lustrous, olive green tablets having the composition $2\text{HgS} \cdot \text{K}_2\text{S}$

Combinations—1 With alkali sulphides, *v supra*, Reactions No 9—2 Forms a compound with hydrogen sulphide, $31\text{HgS} \cdot \text{H}_2\text{S}$ Produced in solution by passing H_2S into HgS suspended in boiled water (Linder a Picton, *C J Proc* 1890 49)—3 With cuprous chloride to form $2\text{HgS} \cdot \text{Cu}_2\text{Cl}_2$, a yellow solid, obtained by boiling HgS with CuCl_2Aq and HClAq , and removing S by CS_2 ($3\text{HgS} + 2\text{CuCl}_2 = 2\text{HgS} \cdot \text{Cu}_2\text{Cl}_2 + \text{HgCl}_2 + \text{S}$) This compound is decomposed by boiling conc HClAq with evolution of a little H_2S and formation of Cu_2Cl_2 and HgCl_2 in solution, dilute hot $\text{H}_2\text{SO}_4\text{Aq}$ has no action, but with boiling conc H_2SO_4 , HCl and SO_2 are evolved and a compound of HgSO_4 and HgS is formed NaOHAq produces NaCl , HgS , and Cu_2O (*v* Heumann, *B* 7, 1390) 4 With mercuric chloride, and also with mercuric bromide, to form compounds $2\text{HgS} \cdot \text{HgX}_2$, ($\text{X} = \text{Cl}$ or Br) These sulphohaloid compounds are formed (a) by passing H_2S into excess of HgCl_2Aq or HgBr_2Aq , (b) by digesting freshly ppd HgS with boiling HgCl_2Aq or HgBr_2Aq (*H Rose*, *P* 13, 59), (c) by adding HCl (or HBr), or solution of a metallic chloride (or bromide), to HgS dissolved in mercuric acetate solution (*Palm*, *C C* 1863 120), (d) by heating HgS with 8-10 parts HgCl_2 or HgBr_2 , till the whole melts, and washing the cold mass with boiling water (Schneider, *P* 115, 167) The compounds are yellow white crystalline powders, decomposed by slow heating to HgS and HgX_2 , decomposed by alkali solutions, but not by HNO_3Aq or $\text{H}_2\text{SO}_4\text{Aq}$ (*cf* Barfoed, *J pr* 93, 230)—5 With mercuric iodide to form the sulpho iodide $\text{HgS} \cdot \text{HgI}_2$, a yellow solid obtained by digesting HgI_2 with less H_2SAq than suffices for complete decomposition (*H Rose*, *P* 13, 59), also by ppg HgO and HgI_2 in HClAq by a small quantity of H_2S (Rammelsberg, *P* 48, 175), also by saturating HgI_2 in HIAq with H_2S , and diluting (Kekulé) *Palm* (*C C* 1863 121) says that the yellow red pp obtained by adding HIAq , or a solution of an alkali iodide, to HgS dissolved in mercuric acetate solution, has the composition $2\text{HgS} \cdot \text{HgI}_2$.—6 With mercuric fluoride, to form the sulphofluoride $2\text{HgS} \cdot \text{HgF}_2$, obtained by passing a little H_2S into HgF_2 dissolved in HFAq (*H Rose*, *P* 13, 59)—7 With mercuric sulphate, to form several compounds, the chief of which are (1) $\text{HgSO}_4 \cdot \text{HgS}$, (2) $\text{HgSO}_4 \cdot 2\text{HgS}$, and (3) $\text{HgSO}_4 \cdot 3\text{HgS}$ These compounds are obtained, (1) by treating red HgS with warm $\text{H}_2\text{SO}_4\text{Aq}$ (*Palm*, *J* 1862 220), (2) by treating $2\text{HgS} \cdot \text{HgNO}_3$ (obtained by passing a little H_2S into $\text{Hg}(\text{NO}_3)_2\text{Aq}$ with $\text{H}_2\text{SO}_4\text{Aq}$ (Barfoed, *J* 1864 282, Kessler, *A Ch* [3] 6, 615), (3) by adding $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$ to $\text{Hg}(\text{NO}_3)_2\text{Aq}$ and removing S by washing with CS_2 (*Spring*, *A* 199, 116, Wackenroder, *A* 60, 190)—8 With mercuric nitrate, to form $2\text{HgS} \cdot \text{Hg}(\text{NO}_3)_2$, a white solid, obtained by passing a little H_2S into $\text{Hg}(\text{NO}_3)_2\text{Aq}$, or by digesting freshly ppd HgS with $\text{Hg}(\text{NO}_3)_2\text{Aq}$, or by ppg a solution of HgS in mercuric acetate by HNO_3Aq or alkali nitrate solution (*H Rose*, Barfoed, *Palm*, *lc*) By heating HgS with HNO_3Aq , S.G. 1.2, to 120° in a closed tube, Gramp

Q

(*J pr* [2] 14, 299) obtained a white crystalline mass of $6\text{HgS} \cdot \text{HgO} \cdot 2\text{Hg}(\text{NO}_3)_2 \cdot 12\text{H}_2\text{O}$

MERCURY COMPOUNDS, ORGANIC Mercury forms compounds with two identical alcohol radicles, or with one alcohol radicle and one acid residue. Compounds of mercury with two different alcohol radicles appear to split up at the moment of their formation, e.g. $2\text{HgEtMe} = \text{HgMe}_2 + \text{HgEt}_2$, (Frankland, *A* 111, 57)

Mercury dimethide $\text{Hg}(\text{CH}_3)_2$, *Mercury dimethyl*. Mol w 230 V D 8.29 (calc 7.97) (93° – 96°)

Formation—1 When mercury is exposed with MeI to sunlight for a week, crystalline CH_3HgI is formed (Frankland, *A* 85, 361). When this body is distilled with KOH, lime, or KOCy, mercury dimethide passes over as a heavy liquid which may be purified by washing with water and rectifying over CaCl_2 (Buckton, *Pr* 9, 91, *A* 108, 103)—2 By the action of sodium-amalgam on MeI (10 pts) in presence of acetic ether (1 pt) (Frankland & Duppa, *C J* 17, 415, *A* 130, 105)

Properties—Colourless oil, with faint but mawkish taste. Insol water, v sol alcohol and ether. Dissolves phosphorus, resins, and caoutchouc. Very inflammable, burning with a bright flame.

Reactions—1 Iodine forms CH_3HgI and methane. Bromine acts in like manner.—2 SnCl_4 forms a crystalline compound which is decomposed by water with formation of CH_3HgCl .—3 Conc HClAq gives methane and CH_3HgCl .—4 Conc H_2SO_4 gives methane and $(\text{CH}_3\text{Hg})_2\text{SO}_4$.—5 PCl_5 gives CH_3HgCl .—6 KMnO_4 oxidises it to CH_3HgOH (Seidel).

Mercuric chloro-methide CH_3HgCl [170°] (Seidel, *J pr* [2] 29, 135) S G 4.063 (Schröder, *B* 12, 563). Formed from HgMe_2 by the action of HCl . Lammæ.

Mercuric iodomethide CH_3HgI [143°] From MeI and Hg in sunlight (Frankland). Formed also by heating HgMe_2 with HgI_2 . Small nacreous lammæ (from ether), insol water, m sol alcohol, v sol ether and MeI. Slightly volatile, emitting an unpleasant odour, and leaving a persistent nauseous taste. May be sublimed.

Mercuric nitromethide CH_3HgNO_2 [100°] From an alcoholic solution of CH_3HgI and AgNO_3 . Nacreous lammæ, v sol water, sl sol alcohol. Its solution is not pptd by KOH or baryta water, but HCl and soluble chlorides ppt CH_3HgCl (Strecker, *A* 92, 79).

Mercuric acetomethide $\text{CH}_3\text{Hg.OAc}$ [148°] Obtained by heating HgMe_2 with acetic acid at 180° (Otto, *Z.* [3] 6, 26). Thin tables,

with very offensive odour, nearly insol boiling water and cold HOAc .

Mercuric chloro-methylo iodide CH_2ClHgI [129°] Obtained by boiling CH_3I with alcoholic HgCl_2 (Sakurai, *C J* 41, 360). Silky plates (from alcohol). Decomposed by iodine into methylene chloro iodide and HgCl_2 .

Mercuric iodo-methylo-iodide CH_2IHgI [109°] Formed by leaving mercury and a little mercurous iodide in contact with methylene iodide in a sealed tube for several days (Wanklyn & Von Than, *C J* 12, 258, Sakurai, *C J* 37, 658). White crystals (from CH_2I_2), insol water, cold alcohol, ether, chloroform, EtI, and benzene, sl sol boiling alcohol, v sol methylene iodide. When heated with iodine dissolved in aqueous KI it is decomposed into CH_2I_2 and HgI_2 . Chlorine and bromine act in like manner. When heated with HClAq it is reduced to CH_3HgI .

Di-mercuric methyleno-di-iodide $\text{CH}_2(\text{HgI})_2$ [$c 230^\circ$] Obtained by exposing a mixture of an ethereal solution of methylene iodide with a little HgI_2 and an excess of mercury to sunlight (Sakurai, *C J* 39, 487). Formed also by the action of mercury on CH_2IHgI . Yellowish crystalline powder, insol all ordinary solvents, sl sol hot methylene iodide. When heated with dilute HClAq or with KIaq it yields CH_3HgI . Iodine forms HgI_2 and methylene iodide.

Mercuric methyleno-tri-iodide $\text{CH}(\text{HgI})_3$. From iodoform, mercury, and alcohol, by exposure to sunlight (Sakurai, *C J* 39, 488). Yellow mass, insol ordinary solvents and in CH_2I_2 . Gives iodoform when treated with iodine.

Mercuric diethide HgEt_2 . Mol w 258 (159°) S G 2.46 V D 9.97 (calc 9.4). Strecker (*C R* 39, 57, *A* 92, 97) by acting on EtI with mercury obtained the compound EtHgI . Dünhaupt (*Chem Gas* 1854, 263, *A* 92, 879) obtained the corresponding EtHgCl and EtHgBr by decomposing bismuth triethide with HgCl_2 or HgBr_2 . Buckton (*A* 109, 218, *C J* 18, 17) obtained HgEt_2 by the action of ZnEt_2 on HgCl_2 , and, lastly, Frankland and Duppa showed that mercuric diethide can be more easily obtained by the action of sodium amalgam on EtI in presence of acetic ether. The acetic ether remains in undiminished quantity at the end of the process, but nevertheless its presence is essential.

Preparation—Ethyl iodide (10 pts) is mixed with EtOAc (1 pt) and poured upon $\frac{1}{2}$ p.c. sodium amalgam, the flask being shaken and cooled in water. When separation of NaI has rendered the liquid pasty it is distilled off from a water bath and shaken with fresh amalgam. Finally it is mixed with water, and the oil dried over CaCl_2 and rectified.

Properties—Transparent colourless liquid, with faint ethereal odour, insol water, sl sol. alcohol and ether. Very poisonous. Burns with smoky flame. Takes fire in chlorine.

Reactions.—1 Acts violently on bromine and iodine, forming EtHgBr and EtHgI (Buckton, *A* 112, 220).—2 Alcoholic HgCl_2 forms EtHgCl .—3 Conc HClAq forms ethane and EtHgCl .—4 H_2SO_4 gives ethane and $(\text{EtHg})_2\text{SO}_4$.—5. *Sodium* forms a bulky grey spongy mass, which

takes fire in air and violently decomposes when heated—6 Heated with finely granulated zinc it yields ZnEt₂ and mercury (Franklanda Duppa, *C J* 17, 29) Cadmium forms CdEt₂. Bismuth gives BiEt₃.—7 Mercuric ethide is decomposed when heated at 150° with copper, iron, silver, or gold, but ethides of these metals are not formed 8 KMnO₄ forms EtHgOH—9 When heated with PCl₅ it forms PEtCl₄.—10 Iodoform at 90° gives acetylene and ethylene (Suida, *M* 1, 716)

Mercuric chloro-ethide EtHgCl [190°] (Seidel) SG 3 48 Formed by the action of HgCl₂ on BiEt₃, by treating HgEt₂ with alcoholic HgCl₂, and by the action of HgCl₂ on ZnEt₂. Ppd by adding NaCl to an aqueous solution of EtHgNO₃. Obtained also by treating EtHgOH with HCl. Light iridescent laminae (from alcohol). Nearly insol water, sl sol ether, v sol boiling alcohol. Sublimes at 40° With Ag₂CO₃ it gives (EtHg)₂CO₃, which crystallises with difficulty and is easily decomposed by heat and by acids. Ag₂PO₄ gives a very soluble phosphate (Dunhaupt)

Mercuric iodomethide EtHgI Formed by the action of mercury on EI in diffused daylight. Decomposed by direct sunlight (Strecker, *A* 92, 75) Shining laminae, insol water, sol alcohol and ether. Sublimes at 100° Dissolves without change in aqueous NH₃ or KOH With ZnEt₂ it yields ZnI₂ and HgEt₂

Mercuric ethylo hydroxide EtHgOH Obtained by adding moist Ag₂O to a boiling alcoholic solution of EtHgCl, filtering, and evaporating *in vacuo*. Strongly alkaline liquid, which blisters the skin. V sol water. Decomposes ammonium salts with expulsion of NH₃. It does not liberate KOH or MgO from their salts, but it ppt salts of Al, Zn, Sn, Cu, Au, and Pt. With a large excess of H₂S it forms a white ppt turning through orange to black. With metallic zinc it forms ZnEt₂. With acids it forms crystalline salts, eg HCl yields EtHgCl

Mercuric bromo ethide EtHgBr **Mercuric ethylo bromide** Formed from BiEt₃ and HgBr₂, or by treating EtHgOH with HBr (Dunhaupt, *A* 92, 379) Resembles EtHgCl

Mercuric ethylo cyanide EtHgCy Formed by saturating an alcoholic solution of EtHgOH with HCN. Crystallises readily, v sol alcohol and ether. Very volatile. Gives off a repulsive odour when heated

Mercuric ethylo nitrate EtHgNO₃, **Mercuric nitro ethide** From EtHgI and AgNO₃. Colourless prisms, v e sol water, m sol alcohol (Strecker)

Mercuric ethylo sulphate (EtHg)₂SO₄ Formed from EtHgCl and Ag₂SO₄. Shining laminae (from alcohol)

Mercuric ethylo sulphide (EtHg)₂S Obtained by adding ammonium sulphide to an alcoholic solution of EtHgCl. Yellowish white powder, v sol alcohol, ether, and CS₂. The alcoholic solution is decomposed by evaporation, leaving HgS

Mercuric ethylo-acetate EtHgOAc [178°] Obtained by dissolving HgEt₂ in HOAc (Otto, *Z* 1870, 25)

Mercuric dipropyl HgPr₂, (190°) (O); (180°) (Sohlscherbakoff, *J R* 18, 353) SG 12 214 Formed by the action of propyl iodide on sodium-amalgam in presence of acetic ether (Cahours,

C. R 76, 133, 1383) Oil, sl sol alcohol, v sol ether. With iodine and bromine it forms products which may be crystallised from alcohol. The effect of small additions of HgPr₂ of Hg(C₂H₅)₂, of Hg(C₃H₇)₂, and of HgPh₂ on the freezing point of ethylene bromide has been studied by Louise and Roux (*C R* 107, 600)

Mercuric diisobutyl Hg(CH₂Pr)₂ (206°) SG 1-1835 Obtained by treating a mixture of isobutyl iodide and acetic ether with 2 p.c. sodium amalgam (Cahours). Colourless liquid. Iodine forms CH₂Pr HgI, whence Ag₂O forms CH₂Pr HgOH. Bromine acts in like manner

Mercuric diisocamyl Hg(C₈H₁₇)₂ SG 2 1666 From isocamyl iodide (5 pts), acetic ether (1 pt), and sodium amalgam (Franklanda Duppa, *A* 130, 110). Colourless oil, decomposed on distillation even *in vacuo*. May be distilled with steam. Insol water, v sl sol alcohol, v sol ether. With chlorine it forms dense fumes of C₈H₁₇HgCl. It reacts with great violence with bromine and iodine. With an alcoholic solution of HgCl₂ it readily forms C₈H₁₇HgCl [86°], which crystallises from alcohol in hair like needles. An ethereal solution of Hg(C₈H₁₇)₂ treated first with an alcoholic solution of iodine and then with solid iodine forms isocamyl iodide and C₈H₁₇HgI [122°], which crystallises from alcohol in pearly scales. With zinc at 130° C₈H₁₇HgI forms zinc isocamyl and zinc amalgam

Mercuric dioctyl Hg(C₈H₁₇)₂ SG 17 1342 Prepared by the action of sodium amalgam on octyl iodide in presence of a little acetic ether (Eichler, *B* 12, 1880). Liquid. Insol water, sol alcohol, ether, and C₆H₆. Decomposes at 200° into Hg and hexadecane (dioctyl)

Mercuric octylo iodide C₈H₁₇HgI white silky pp. Prepared by the action of an alcoholic solution of iodine on mercury dioctyl

Mercuric octylo chloride C₈H₁₇HgCl White pp. Prepared by the action of mercuric chloride on mercury dioctyl

Mercuric octylo-hydroxide C₈H₁₇HgOH [75°] Prepared by the action of silver oxide on an alcoholic solution of mercury dioctyl (Eichler, *B* 12, 1881). Yellow leaflets. Insol cold, sl sol hot, water, v sol alcohol. Alkaline

Mercuric allylo-iodide C₃H₅HgI [135°] S (CS₂) 187 at 49° Formed by shaking allyl iodide with mercury, and extracting the resulting yellow mass with hot alcohol or ether (Zinin, *A* 96, 363, cf Linnemann, *A* 140, 180). It is best to mix the allyl iodide with an equal volume of alcohol (Oppenheim, *B* 4 670). Silvery scales, which turn yellow on exposure to light, especially on drying. It even turns yellow in the dark. Sublimes at 100° Sl sol cold alcohol, nearly insol water. Decomposes above its melting point. AgNO₃ added to its alcoholic solution ppt all the iodine as AgI. Moist Ag₂O ppt AgI, and the filtrate on evaporation leaves a strongly alkaline syrupy mass which forms salts with acids. HI easily decomposes it, forming HgI₂ and propylene. Iodine forms HgI₂ and allyl iodide (Linnemann, *A* 133, 133, *Suppl* 3, 262). PBr₃, acetyl chloride, and BzCl have no action on mercuric allyl iodide. On shaking it with a solution of ZnEt₂ in ether an energetic reaction sets in, the products being mercury, ZnI₂, diallyl, and HgEt₂. A solution

of K₂O acts quickly in the cold, forming diallyl, mercury, HgCy₂, and KI, if in distilling off the diallyl the distillation is not stopped in time an explosion occurs. Aqueous KI at 100° forms mercury, diallyl, and KHgI. The mercury allyl compounds attack the skin, producing blisters which appear after the lapse of 7 hours. The compound C₃H₅HgCl obtained by the action of HCl on the hydroxide is sparingly soluble (Krasowsky, *Z* 6, 527).

Mercuric propargyl iodide C₃H₃HgI. From propargyl iodide and mercury (Henry, *B* 17, 1152). Small yellowish crystalline masses.

Mercuric diphenyl Hg(C₆H₅)₂ [120°] (above 800°) SG 2318. Formed by heating a mixture of bromo benzene, benzene, HgCl₂, and sodium (Michaelis a. Reese, *B* 15, 2876). Prepared by boiling for some time a solution of bromo-benzene (10 pts) in an equal volume of xylene with 27 p.c. sodium amalgam and a little acetic ether (1 pt). The product is recrystallised from benzene (Dreher a. Otto, *Z* [2] 4, 685, 6, 9, *A* 154, 93). Small white needles or prisms, turning yellow in daylight. Insol water, v sol chloroform, CS₂, and benzene, m sol ether and boiling alcohol. May be sublimed. Partially decomposed on distillation into mercury, diphenyl, benzene, and charcoal.

Reactions—1 Dry HCl gives benzene and HgCl₂. HI, nitric acid, HBr, and H₂SO₄ act in like manner.—2 When melted with sulphur (2 at) the products are HgS and phenyl mercaptan.—3 Iodine (2 at) in alcoholic or CS₂ solution forms PhHgI and iodobenzene. Excess of iodine forms HgI₂ and iodo benzene.—4 Chlorine forms PhHgCl and chloro benzene. Br acts in like manner.—5 Glacial acetic acid yields benzene and PhHgOAc.—6 Aluminium foil at 130° forms AlEt₃ [230°] (Friedel a. Crafts, *A Ch* [6] 14, 460).—7 Alcoholic HgCl₂ at 100° gives PhHgCl.—8 When boiled with sodium, benzene and sodium amalgam are formed.—9 SO₂ gives mercuric benzene sulphonate (Otto, *J pr* [2] 1, 179).—10 Allyl iodide forms diallyl, diphenyl, and PhHgI (Suida, *M I* 715).—11 C₆H₅SO₂Cl at 160° forms C₆H₅SO₂C₆H₅ and PhHgCl (Otto, *B* 18, 246).—12 COCl₂ CO₂Et forms phenylglyoxylic ether (Claisen a. Morley, *B* 11, 1596). 13 When oxidised by KMnO₄ the hydroxide PhHgOH is probably first formed, but on adding HCl this is changed to PhHgCl (Seidel, *J pr* [2] 29, 134, Otto, *J pr* [2] 29, 136).

Mercuric phenylo chloride C₆H₅HgCl. **Mercuric chlorophenylide** [250°]. Obtained by slowly passing chlorine over HgPh₂ or into its solution in CS₂. Prepared by heating HgPh₂ with HgCl₂ in alcoholic solution at 110°. Trimetric tables (from benzene). May be sublimed. Sl sol alcohol and benzene, insol water.

Mercuric phenylo-bromide C₆H₅HgBr [275°]. Resembles the preceding in preparation and properties. Br forms HgBr₂ and bromobenzene. When heated with an alcoholic solution of K₂S the products are KBr, HgS₂, and HgPh₂.

Mercuric phenylo-iodide C₆H₅HgI [266°]. From HgPh₂ and I in alcohol. Satiny tables (from alcohol benzene). Insol water, nearly insol. cold alcohol, ether, and benzene, m. sol. hot benzene and chloroform, v. sol. CS₂.

May be partially sublimed. Sodium amalgam reduces it in alcoholic solution to HgPh₂.

Mercuric phenylo hydroxide C₆H₅HgOH. From PhHgCl by boiling with alcohol and moist Ag₂O. White trimetric prisms (from alcohol), sol boiling water, alcohol, and benzene, sl sol cold water. Softens at 160°, but is not melted at 200°. The aqueous solution is alkaline in reaction. Expels NH₃ from its salts, ppts alumina from alum, and absorbs CO₂ from the air.

Mercuric phenylo cyanide PhHgCy. [204°]. From HgPh₂ and HgCy₂ in alcoholic solution at 128°. Long slender trimetric prisms, v sl sol boiling water, m sol boiling alcohol and benzene. Conc HClAq at 120° forms HgCl₂, formic acid, benzene, and NH₃. Alcoholic KOH forms mercury, benzene, and potassium cyanate. Iodine forms PhHgI and ICy. H₂S forms HgS, benzene, and HCy.

Mercuric phenylo-sulphocyanide PhHgSCy [227°]. From HgPh₂ and Hg(SCy)₂. Silky plates, sol boiling alcohol.

Mercuric phenylo-nitrate PhHgNO₃ [c 167°]. From PhHgCl and AgNO₃ in alcohol. Trimetric silky plates, v sl sol boiling water. Conc HClAq gives benzene and mercuric nitrate.

Mercuric phenylo carbonate (PhHg)₂CO₃. From PhHgCl and Ag₂CO₃. Small white needles, sl sol boiling water, m sol boiling alcohol and benzene. Not decomposed on fusion.

Mercuric phenylo-formate PhHgOCHO [171°]. From HgPh₂ and concentrated formic acid. Small tables.

Mercuric phenylo acetate PhHgOAc. [149°]. Obtained by boiling HgPh₂ with excess of HOAc, ppg with water, and crystallising from hot water. Radiate groups of prisms, sl sol cold, m sol hot, water, m sol alcohol and benzene. Decomposed by distillation yielding diphenyl, benzene, AcO, HOAc, carbon, and mercury. Boiling aqueous HCl forms benzene, HgCl₂, and HOAc. Other mineral acids act in like manner. Sodium amalgam reduces it in alcoholic solution to benzene. Iodine, acting on its aqueous solution, forms HgI₂, iodo benzene and HOAc. H₂S forms HgS, benzene, and HOAc.

Mercuric phenylo-propionate PhHgOC₂H₃O [c 166°]. From HgPh₂ and boiling propionic acid. Crystals, sol hot water, alcohol, and benzene.

Mercuric phenylo-myristate PhHgOC₄H₇O. From HgPh₂, myristic acid, and alcohol at 120°. Small scales, sol boiling alcohol and benzene. Boiling HClAq splits it up into HgCl₂, benzene, and myristic acid (Otto, *J pr* [2] 1, 179).

Mercuric tetra-methyl-di-amido-di-phenyl (NMe₂C₆H₄)₂Hg [169°]. Formed by the action of sodium amalgam in presence of EtOAc on *p*-bromo-di-methyl-aniline dissolved in xylene (Sohenk a. Michaelis, *B* 21, 1501). Colourless crystals, turning green in air. Crystallises from benzene with C₆H₆ (1 mol.) v sol chloroform, and benzene, v sl sol alcohol and ether.

Mercuric di-*o*-tolyl Hg(C₆H₄Me)₂ [107°]. From *o* bromo toluene sodium-amalgam, and

acetic ether (Ladenburg, *A* 178, 162). Large trichinic tables (from benzene)

Mercuric o-tolylo-chloride

[2] $C_6H_4MeHgCl$ *o*-Tolyl-mercuric chloride [146°] Formed by treating mercuric *o* tolyl with $HgCl_2$ in ethereal solution (Michaëlis a Genzken, *A* 242, 180) Needles, v sol chloroform, m sol alcohol and benzene, sl sol ether and petroleum ether Sublimes with partial decomposition

Mercuric m-tolylo-chloride

[3] $C_6H_4MeHgCl$ [160°] Obtained by boiling $(C_6H_4Me)_2SbHgCl_2$ with alcohol (M a G) Needles (from alcohol), v sol chloroform and benzene, m sol alcohol H_2S passed into its alcoholic solution ppts HgS

Mercuric di-p tolyl $Hg(C_6H_4Me)_2$ [238°] Formed from *p* bromo toluene, sodium amalgam, and $EtOAc$ (Dreher a Otto, *A* 154, 171, Ladenburg, *A* 173, 163) Needles or tables, insol water, sl sol cold alcohol, m sol hot benzene, CS_2 , and $CHCl_3$ May be distilled Boiling conc $HClAq$ gives toluene and $HgCl_2$

Mercuric p tolylo chloride

$C_6H_4MeHgCl$ [187°] Small tables (Otto, *J pr* [2] 1, 185)

Mercuric p tolylo iodide C_6H_4MeHgI [220°] From mercuric di *p* tolyl and iodine Trimetric satiny tables, insol water, sl sol boiling alcohol, m sol hot benzene May be sublimed

Mercuric p tolylo-acetate

$C_6H_4MeHgOAc$ [153°] Small trimetric prisms, nearly insol cold water, sl sol boiling water, m sol alcohol Behaves like the corresponding phenyl compound

Mercuric di-p xylyl $(C_6H_4Me)_2Hg$ [123°]

Prepared by the action of sodium amalgam on bromo *p* xylene (Jacobsen, *B* 14, 2112) Thick prisms, sol CS_2 , chloroform, and benzene, sl sol alcohol and ether

Mercuric di-m-xylyl [1 3 4] $(C_6H_4Me)_2Hg$ [170°] From bromo *m* xylene and 2 *p* c sodium amalgam by heating at 145° for 12 hours (Weller, *B* 20, 1718) Slender felted needles, sl sol ether, alcohol, and cold benzene, v sol hot benzene Boiling $HClAq$ gives $HgCl_2$ and *m* xylene PCl_5 forms $C_6H_4Me_2PCl_2$ (257°) and $C_6H_4Me_2HgCl$

Mercuric di n-propyl-di phenyl $Hg(C_6H_5Pr)_2$ [110°] From BrC_6H_5Pr [1 4] and sodium-amalgam (R Meyer, *J pr* [2] 34, 103) Long needles

Mercuric di cymyl $Hg(C_{10}H_{11})_2$ [134°]

Formed by heating a mixture of bromo cymene with xylene and sodium amalgam with addition of a little acetic ether (Paternò a Colombo, *B* 10, 1749) Long slender needles, m sol boiling alcohol, benzene, and xylene

Mercuric di pentamethyl-phenyl $Hg(C_6Me_5)_2$

[266°] From bromo-pentamethyl-benzene, chloroformic ether, and sodium-amalgam (Jacobsen, *B* 22, 1220) Prisms (from xylene), v sl sol alcohol and ether, v sol hot xylene

Mercuric di-naphthyl $Hg(C_{10}H_7)_2$ Mol w

464 [243°] SG 1.93 (Schröder, *B* 12, 564) Formed by boiling (a) bromo naphthalene with several times its volume of crude xylene, pasty sodium-amalgam, and a little acetic ether for 19 hours, and filtering while hot (Otto a Moraes, *A* 147, 164, *Z* [2] 3, 877, 4, 162). Small minute, trimetric prisms (from benzene

or CS_2) Not affected by air or light Insol water, sl sol boiling alcohol, cold benzene or ether, m sol hot CS_2 , chloroform, and benzene Decomposed by heat Conc $HIAq$ forms HgI_2 and naphthalene HCl and HBr act in a similar way Iodine forms HgI_2 , $C_{10}H_7HgI$, and ultimately $C_{10}H_7I$ It does not react with $HgCl_2$

Mercuric naphthyllo-bromide

$C_{10}H_7HgBr$ [196°] From $Hg(C_{10}H_7)_2$ and bromine Formed also by heating $Hg(C_{10}H_7)_2$ with $HgBr_2$ Needles, insol water, sol hot alcohol

Mercuric naphthyllo iodide $C_{10}H_7HgI$ [185°] From mercuric di naphthyl and iodine (1 mol) in CS_2 Soft satiny needles or dendritic groups Not altered by light, insol water, sl sol hot alcohol and benzene Sodium-amalgam converts it into mercuric di naphthyl

Mercuric naphthyllo acetate

$C_{10}H_7HgOAc$ [154°] Formed, together with naphthalene, by heating mercuric di naphthyl with excess of $HOAc$ Small needles (from alcohol), insol water, v sol hot $HOAc$, alcohol, CS_2 , benzene, and chloroform, m sol ether Hot $HClAq$ gives naphthalene and $HOAc$ Sodium amalgam acting on its alcoholic solution forms naphthalene and $HOAc$ Water at 140° has no action

Mercuric naphthyllo butyrate

$C_{10}H_7HgOC_4H_9O$ [200°] Very slender needles, sol hot water

MESACONIC ACID $C_6H_4O_4$ *aa*

$CH_2C(CO_2H)CHCO_2H$ Mol w 130 [202°] S 2.7 at 18°, 118 at 100° (Pebal, *A* 78, 130), 2.6 at 14°, 3.4 at 22° (Baup, *A* 81, 97) S (90 p c alcohol) 30.6 at 17°, 95.7 at 78° (P), (88 p c alcohol) 38 at 22° (B) R_{20} 46.9 in a 3.69 p c aqueous solution (Kanonnikoff, *J pr* [2] 31, 349) Heat of solution - 5493 Heat of combustion 27,334 (Gal a Werner, *Bl* [2] 47, 159) H C 479.063 (Lougounne, *C R* 106, 1291)

Formation—1 By boiling a dilute solution of citraconic acid for half an hour with one-sixth of its volume of nitric acid Mesaconic acid is deposited on cooling (Gottheb, *A* 77, 268, Pebal, *A* 78, 129, Baup, *A* 81, 96)—2 By boiling citric acid with conc $HIAq$ or $HBrAq$ (Kekulé, *A Suppl* 2, 94, Fitig, *A* 188, 77, 80). 3 By heating a conc aqueous solution of itaconic or citraconic acid at 180° to 200°, CO_2 and an empyreumatic oil being also formed (Swarts, *Bull Acad. Royale Belgique*, [2] 36, No 7) 4 From *citra-* and *mesa-* di bromo pyrotartaric acids by heating with KI and copper at 150° (Swarts, *Z* 1868, 259)—5 The mono-anilide is heated with (3 mol of) KOH and a little water for 1½ hours in the water bath The aniline separates out and is removed by means of ether, the acid being ppd by means of SO_2H_2 (Anschütz, *A* 254, 136)—6 'Oxy-tetric acid,' which is formed from methyl aceto acetic acid by successive treatment with bromine and alcoholic potash (Demarçay, *A Ch* (5) 20, 473), is identical with mesaconic acid (Gorboff, *J R* 1887, 605, Cloëz, *Bl* [3] 3, 698, 602)

Preparation—By evaporating a mixture of citraconic anhydride (10 pts), water (22 pts), and conc HNO_3 (3 pts), until red fumes begin to appear The product is crystallised from water (Fitig, *A* 188, 73)

Properties—Slender needles (from water) or

prisms (from alcohol), sl sol cold, v sol hot, water V sol alcohol and ether. May be sublimed without decomposition. Its molecular weight, determined by Raoult's method, is identical with that of citraconic and of itaconic acid (Paternò, *B* 21, 2157). Mesaconic acid is slightly coloured by FeCl_3 , and the solution when boiled yields a brown gelatinous pp which re-dissolves on cooling. The addition of more FeCl_3 prevents its re-dissolving. Neutral solutions of mesaconates give a brown pp with FeCl_3 , insoluble in excess of the reagent or when heated.

Reactions—1 Conc HIAq at 160° forms pyrotartaric acid—2 Sodium amalgam also reduces it to pyrotartaric acid. The same reduction may be effected by zinc dust (Bottinger, *B* 9, 1821)—3 Bromine has no action in the cold (difference from citraconic acid) but above 60° it combines, forming meso di bromo pyrotartaric acid [170°] (Kekulé, *A Suppl* 2, 85)—4 Chlorine passed into water in which mesaconic acid is suspended forms a solution which when evaporated leaves chloro citramalic acid $\text{C}_4\text{H}_5\text{ClO}_4$ (chloro oxy pyrotartaric acid). The same acid is formed, together with tri chloro acetone, by passing chlorine into an aqueous solution of sodium mesaconate—5 Does not combine with HBr in the cold, but by prolonged heating with HBrAq at 100° or 140° it is converted into citra bromo pyrotartaric acid, an acid that is formed also by the union of HBr with citraconic acid in the cold—6 When repeatedly heated with fuming HClAq at 160° it is converted into citra chloro pyrotartaric acid [130°], which is decomposed by boiling water into HCl and mesaconic acid (Swarts)—7 The electrolysis of potassium mesaconate yields, at the positive pole, CO , and allylene (Aarland, *J pr* [2] 6, 256, 7, 142)—8 AsCl_3 forms citraconic anhydride. Mesaconic anhydride has not been obtained (Petrì, *B* 14, 1636)—9 On evaporating a solution of the aniline salt water is not eliminated from the molecule (difference from citraconic acid).

Salts— $\text{NH}_4\text{A}''$ S 12.5 at 15° . Very small prisms— BaA'' 4aq. monoclinic crystals, more sol water than barium citraconate and itaconate (Petrì, *B* 14, 1634)— BaHA'' 2aq. pearly hexagonal plates— CaA'' 5aq. S 6 at 20° . Very small needles, insol alcohol— PbA'' 1½aq. deposited in the cold as a crystalline pp, v sl sol water— PbA'' 4aq. deposited from a hot solution as an amorphous pp— $\text{PbH}_2\text{A}''$ (dried at 100°). Small needles— $(\text{HO Pb})_2\text{A}''$ 2 ppd by adding lead subacetate to a solution of sodium mesaconate (Otto, *A* 127, 182)— CuA'' 2aq— AgA'' crystalline pp, sl sol water— AgHA'' needles, m sol hot water.

Methyl ether MeA'' (205° 1 V) S 8 at 15° SG $\frac{15}{15}$ 1.1254, $\frac{30}{15}$ 1.1138 MM 1.154 at 24° μ_D 1.4564 at 16° (Gladstone), 1.4570 at 17° (Knops, *A* 248, 195), μ_H 1.4813 at 16° (Gladstone). From the acid, MeOH , and HCl (Perkin, *C J* 39, 556).

Ethyl ether (229° 1 V) SG $\frac{15}{15}$ 1.051, $\frac{30}{15}$ 1.039 (Perkin), $\frac{32}{15}$ 1.0468 (Knops, *A* 248, 196) MM 1.168 at 25° μ_D 1.4433, μ_H 1.4727 at 16° (Gladstone, cf Knops). Formed by the action of alcohol and HCl on mesaconic and on citraconic acids.

Chloride $\text{C}_4\text{H}_4(\text{COCl})_2$. (80° at 17 mm).

Prepared by the action of PCl_5 on mesaconic acid or citraconic anhydride (Petrì, *B* 14, 1634). Colourless liquid.

Amide $\text{C}_4\text{H}_5\text{O}_2(\text{NH}_2)_2$: [177°], colourless flat crystals, sol water.

Anilide $\text{C}_4\text{H}_5\text{O}_2(\text{NHPh})_2$ [186°], flat white silky needles, sol alcohol and ether, sl sol water. Heated to 268° it decomposes into aniline and citraconenil (the phenylimide of citraconic acid) (O Strecker, *B* 15, 1639).

Mono anilide $\text{C}_4\text{H}_5(\text{CO}_2\text{H})(\text{CONHPh})$. [158°] Formed by heating citraconic anhydride with aniline at 170° , rectifying *in vacuo* the resulting phenylimide (172° at 12 mm), dissolving it in baryta water, ppg excess of barium by CO_2 , and then adding HCl (Anschutz, *A* 254, 133). Identical with the product which separates from an aqueous solution of acid aniline citraconate on standing. White powder. Converted by heating in a sealed tube with KOH into mesaconic acid.

Constitution—Mesaconic acid stands to citraconic acid in the same relation that fumaric acid stands to maleic acid. This is shown by their behaviour towards Br, HBr, and aniline, and by the physical constants of their ethers. Hence mesaconic acid is methyl fumaric acid, while citraconic acid is methyl malic acid. The constitution of mesaconic acid will therefore be known as soon as that of fumaric acid has been satisfactorily determined (v MALEIC ACID).

MESA-DI BROMO PYROTARTARIC ACID α . DI BROMO PYROTARTARIC ACID

TRIMESIC ACID $\text{C}_6\text{H}_3\text{O}_6$, α $\text{C}_6\text{H}_3(\text{CO}_2\text{H})_3$ [135] Benzene α tri carboxylic acid Mol w 210 [α 325°] H C v 768,500 H C p 767,600 H F 285,400 (Stohmann, Kleber & Langbein, *J pr* [2] 40, 140).

Formation—1 By the oxidation of mesitylene or mesitylenic acid by chromic acid mixture (Fittig, *A* 141, 153)—2 By the oxidation of uvitic acid (Baeyer, *Z* 1868, 119, Fittig, *A* 147, 301), and of α tri ethyl benzene (Jacobsen, *B* 7, 1435, Friedel & Baisohn, *Bl* [2] 34, 636) by chromic acid mixture—3 One of the products obtained by heating hydromellitic or isohydromellitic acid with conc H_2SO_4 (Baeyer, *A Suppl* 7, 40, 48)—4 By heating mellitic acid with glycerin (Baeyer, *A* 166, 340)—5 In very small quantity by fusing the corresponding bromo benzene sulphonic acid with sodium formate (Bottinger, *B* 7, 1781)—6 By fusing benzene α trisulphonic acid with KCy , and saponifying the resulting nitrile with KOH (Jackson & Wing, *Am* 9, 347)—7 From di sodium saheylate $\text{C}_6\text{H}_4(\text{ONa})_2\text{CO}_2\text{Na}$ by heating in a current of carbonic acid, converting the resulting $\text{C}_6\text{H}_4(\text{OH})(\text{CO}_2\text{H})_2$ into $\text{C}_6\text{H}_4\text{Cl}(\text{CO}_2\text{H})_2$, and reducing with zinc and dilute acids—8 By the polymerisation of propionic acid, which takes place to some extent when it is exposed for some weeks to sunlight, air being excluded (Baeyer, *B* 19, 2185)—9 Trimesic ether is formed by the action of sodium upon a mixture of ethyl formate and ethyl acetate, formyl acetic ether $\text{HCO CH}_2\text{CO}_2\text{Et}$ is probably first formed and subsequently condensed (Putti, *B* 20, 537). When mixtures of methyl formate and ethyl acetate, or of ethyl formate with methyl acetate

are used a mixture of ethyl and methyl trimesates is obtained

Properties—Colourless prisms (from water), partially sublimes before melting M sol cold water and ether, v sol hot water, v e sol alcohol When distilled with lime it yields benzene

Salts— $\text{NaH}_2\text{A}'''$ plates, sl sol cold water— $\text{Na}_2\text{A}'''$ — $\text{KH}_2\text{A}'''$ needles, sl sol cold water— $\text{Ca}_2\text{A}'''$, aq nodules— $\text{Ba}_2\text{A}'''$, aq (dried at 150°) needles, almost insol cold, v sl sol boiling water (difference from mesitylenic acid)— $\text{BaH}_2\text{A}'''$, 2aq slender hair like needles, sl sol cold water— $\text{Zn}_2\text{A}'''$, 2aq glittering prisms, almost insol cold water— $\text{Cu}_2\text{A}'''$, 2aq (dried over H_2SO_4) Pale blue pp— $\text{Ag}_2\text{A}'''$

Methyl ether $\text{Me}_2\text{A}'''$ [143'] Small silky needles H F 249,500 (Stohmann, *J pr* [2] 40, 353)

Ethyl ether $\text{Et}_2\text{A}'''$ [133'] Prepared by adding a mixture of formic and acetic ethers by drops to twice the amount of ether, in which sodium is placed On adding dilute H_2SO_4 , an oil is obtained, which gives a blue violet colour with FeCl_3 , and on standing in a desiccator deposits crystals of trimestic ether (Wiskenus, *B* 20, 29 10) Long glistening prisms A mixture of this ether and the preceding in equal proportions melts at 105° to 110°

Sulpho trimestic acid *Amide*

$\text{C}_6\text{H}_2(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_2$ Formed by oxidising the amide of either of the sulpho mesitylenic acids with KMnO_4 (Jacobsen, *A* 206, 203)— $\text{KH}_2\text{A}'''$, 2aq crystalline mass, m sol water Conc HCl aq at 210° gives trimestic acid, NH_3 , and H_2SO_4 Potash fusion gives oxy trimestic acid

MESICERIN v TRI OXY MESITYLENE

MESIDIC ACID v UVITIC ACID

MESIDINE $\text{C}_6\text{H}_3\text{N}$ v e

$\text{C}_6\text{H}_2(\text{CH}_3)_2\text{NH}_2$ [1 3 5 6] *Amido mesitylene* (229') (Ladenburg, *A* 179, 172) SG 963

Formation—1 By boiling nitro mesitylene with tin and HCl aq (Fitting a Storer, *A* 147, 1)—2 From di methyl aniline methyl iodide, by heating in a sealed tube at 335° (Hofmann, *B* 5, 715, 8, 61)—3 By heating *um* xyldine hydrochloride or *cm* xyldine hydrochloride with methyl alcohol at 300° (Eisenberg, *B* 15, 1012, Nolting a Forel, *B* 18, 2631)—4 By heating aniline hydrochloride with MeOH at 300° (Lumpach, *B* 21, 640)

Properties—Liquid Gives *m* xyloquinone on oxidation When heated with MeOH and HCl for forty eight hours at 230° it yields dimethyl mesidine (c 215°) ClCO Et yields $\text{O}_2\text{H Me}$, $\text{NH CO}_2\text{Et}$ [629'] (Eisenberg, *B* 15, 1016)

Salts— B^+HCl feathery crystals or prisms, v sol water and alcohol— $\text{B}^+\text{H}_2\text{SnCl}_4$ Sparingly soluble needles— $\text{B}^+\text{H}_2\text{PtCl}_6$ — $\text{B}^+\text{H}_2\text{H}_2\text{O}_4$ plates, sl sol cold water

Acetyl derivative $\text{C}_6\text{H}_2(\text{CH}_3)_2\text{NHAc}$ [217'] Prisms (from alcohol) May be sublimed

Benzoyl derivative $\text{C}_6\text{H}_2(\text{CH}_3)_2\text{NHBz}$ [204'] Needles (Schaek, *B* 10, 1711)

MESIDINE SULPHONIC ACID $\text{C}_6\text{H}_2\text{NSO}_3$

MESITYLENE C_6H_6 ψ e $\text{C}_6\text{H}_5\text{Me}$, [135]

s-Tri-methyl benzene Mol w 120 (164.5°)

(Schiff, *A* 220, 94) S G $\frac{8}{8}$ 8694 (S), $\frac{2}{2}$ 8558 (Bruhl, *A* 200, 190) CE (9.8° to 161.5°) 001159 (S) VD 4.4 (obs and calc) SV 162.4 (Schiff), 162.2 (Rumery) $\mu_p = 1.5015$ $R_\infty = 65.75$ (B) $\text{H C} = 1,251,660$ [$\text{C}_6\text{O}_2 = 94,000$, $\text{H}_2\text{O} = 69,000$] (Stohmann, *J pr* [2] 85, 41), 1,282,310 (Thomsen, *Th* 4, 63) $\text{H F p} = 490$ $\text{H F v} = -2410$ (*Th*)

Occurs in coal tar oil (Fittig a Wackenroder, *A* 151, 292, Jacobsen, *A* 184, 179, *B* 9, 256, 10, 855) It is also one of the products of the manufacture of oil gas (Armstrong, *C J* 49, 74) Occurs in all kinds of petroleum (American, Russian, &c) (Engler, *B* 18, 2234)

Formation—1 By distilling acetone with H_2SO_4 (Kane, *P* 44, 474, Hofmann, *C J* 2, 101, Cahours, *C R* 24, 255, *C J* 3, 17)—2 By the action of H_2SO_4 on allylene (Fittig a Schroebe, *B* 8, 17)—3 By treating toluene with MgCl in presence of AlCl_3 , ψ cumene being also formed (Friedel a Crafts, *A Ch* [6] 1, 461, Ador a Rilliet, *B* 12, 329)

Preparation—1 By mixing 180 g acetone with 800 g sulphuric acid, allowing to stand for an hour, then distilling gently, using a current of steam at the end of the operation The yield is 40 g (Varenne, *Bl* [2] 40, 266)—2 H_2SO_4 (2 vols) diluted with water (1 vol) is slowly added to a mixture of crude acetone (2 vols) and sand After 24 hours the mixture is distilled The oil thus obtained is washed with aqueous NaOH and rectified (Fittig a Bruckner, *A* 147, 42)—3 The fraction of coal tar oil boiling between 160° and 168° is agitated with H_2SO_4 and the resulting sulphonic acids converted first into Ba salts and then into Na salts The Na salts are then treated with PCl_5 and the resulting chlorides converted into amides by NH_3Aq . On crystallising from alcohol, the ψ cumene sulphonamide separates first, and then mesitylene sulphonamide The mesitylene sulphonamide is then heated with conc HClAq at 160° (Jacobsen)—4 The sulphonic acids of ψ cumene and of mesitylene may also be separated by heating

with HClAq at 100° for 1 hour, when mesitylene sulphonic acid is decomposed into mesitylene and H_2SO_4 , while ψ cumene sulphonic acid is not affected (Armstrong, *B* 11, 1697)—5 When steam is passed through a heated solution of mesitylene sulphonic acid in dilute H_2SO_4 , hydrolysis into mesitylene and H_2SO_4 begins as soon as the temperature reaches 100° (Armstrong a Miller, *C J* 45, 148)

Properties—Light oil

Reactions—1 Br and Cl form crystalline substitution products—2 Fuming HNO_3 mixed with fuming H_2SO_4 forms tri nitro mesitylene, 3 Boiling dilute HNO_3 oxidises it to mesitylenic acid and uvitic acid (Fittig, *A* 141, 142)—4 $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 yield acetic acid (Fittig) 5 KMnO_4 oxidises it to uvitic and trimelic acids (Jacobsen, *A* 184, 191)—6 When heated with AlCl_3 in a current of HCl it yields MgCl and *m* xylene, toluene, and benzene (Jacobsen, *B* 18, 312)—7 MeI in presence of AlCl_3 yields (1, 2, 4, 5) tetra-methyl benzene (durene) (Barbier a Roux, *Bl* [3] 2, 4)—8 Benzyl chloride and AlCl_3 at 100° form benzyl mesitylene (q v) 9 Benzoyl chloride in presence of aluminium chloride forms phenyl tri methyl phenyl ketone $\text{C}_6\text{H}_5\text{COCH}_2\text{Me}$, [36°] and the compounds $(\text{C}_6\text{H}_5\text{CO})_2\text{CMe}$, [117°] and $(\text{C}_6\text{H}_5\text{CO})_3\text{CMe}$, [215°] (Louise, *A Ch* [6] 6, 200)—10 PCl_5 at 180° gives a small quantity of $\text{C}_6\text{H}_5(\text{CH}_2\text{Cl})$, (Colson a Gautier, *Bl* [2] 45, 6)—11 Mesitylene is very readily attacked by halogens In the dark, mono- di- or tri- (*eso*) bromo mesitylene ($\text{C}_6\text{H}_4\text{Me}_2\text{Br}$, $\text{C}_6\text{H}_3\text{Me}_2\text{Br}_2$, and $\text{C}_6\text{Me}_3\text{Br}_3$) are formed according as 1, 2, or 3 mols of bromine are employed Chlorine acts similarly The presence of iodine, though not required, does not effect the reaction At the boiling point the bromine, as usual, enters the side chains, 1 mol Br forming ω bromo mesitylene (mesityl bromide) $\text{C}_6(\text{CH}_3)_2\text{CH}_2\text{Br}$ melting at [38°] Direct sunshine, which usually acts like heat, in the case of mesitylene, owing to the great tendency to displacement of the nuclear hydrogen, produces a different result, (*eso*) mono bromo mesitylene is first produced but is partly attacked by the rest of the bromine forming the liquid p ω di-bromo mesitylene (p bromo mesityl bromide) $\text{C}_6\text{H}_4(\text{CH}_3)_2\text{Br}(\text{CH}_2\text{Br})$ [53.4.1] If *eso* bromo mesitylene be exposed to further bromination in sunshine, the reaction proceeds normally, producing p ω di bromo mesitylene (as above), and, on further action, p ω - α_2 tri bromo mesitylene $\text{C}_6\text{H}_3(\text{CH}_3)_2\text{Br}(\text{CH}_2\text{Br})_2$ [54.3.1] melting at [122°] (Schramm, *B* 19, 212)—12 When a 10 p solution of mesitylene in CS_2 is mixed with a similar solution of chromyl chloride CrO_2Cl_2 a pp ($\text{C}_6\text{H}_4\text{Me}_2$)(CrO_2Cl_2) is obtained which when decomposed by water yields di methyl benzoic aldehyde (221°), which is oxidised by air to mesitylenic acid (Etard, *C R* 97, 909)—13 The diacetyl derivative of *ortho formic aldehyde* (1 pt) mixed with mesitylene (1 pt) and HOAc (10 pts) condenses on adding a mixture of HOAc (10 pts) with an equal volume of H_2SO_4 , and after 24 hours crystals of $(\text{C}_6\text{H}_4\text{Me}_2)_2\text{CH}_2$ [130°] separate The formation of this body may be used as a test for mesitylene, a mixture of methyl alcohol and CrO_3 in HOAc being used instead of $\text{CH}_3(\text{OAc})_2$ (Baeyer, *B* 5, 1094, 6, 220)

Constitution.—The explanation of the for.

mation of mesitylene by condensation of acetone was first given by Baeyer (A 140, 306). That the three methyls are symmetrically situated in the benzene nucleus would appear from the existence of only one mono-derivative derived by displacing an atom of hydrogen in the nucleus, *eg* there is only one nitro-mesitylene. A systematic proof of the symmetry of mesitylene has been given by Ladenburg (A 179, 163). He prepares in succession $C_6Me_3(NO_2)(NO_2)H$, $C_6Me_3(NO_2)(NH_2)H$, $C_6Me_3(NO_2)(NH_2)(NO_2)$, and $C_6Me_3(NO_2)H(NO_2)$. Since the last di-nitro-mesitylene is identical with the first, the second and third hydrogen atoms are similarly situated in the nucleus. Again, from the above nitro-mesidine $C_6Me_3(NO_2)(NH_2)H$ Ladenburg obtained $C_6Me_3(NO_2)HH$ and, by reducing this, mesidine $C_6Me_3(NH_2)HH$. Nitro-mesidine, obtained by nitrating $C_6Me_3(NH_2)HH$, must be either $C_6Me_3(NH_2)(NO_2)H$ or $C_6Me_3(NH_2)H(NO_2)$. But since it has been shown that the second and third atoms of hydrogen are similarly situated, these two formulae are identical. And since the nitro-mesidine is found to be identical with the $C_6Me_3(NO_2)(NH_2)H$ prepared from the di-nitro-mesitylene $C_6Me_3(NO_2)(NO_2)H$, it follows that the first and second atoms of hydrogen are similarly situated. Hence all three atoms of hydrogen are similarly situated, and the formula will be $C_6Me_3H_3$ [1 3 5].

Mesitylene hexahydride C_6H_8 , *ie* $C_6Me_3H_3$, (*c* 137°). Obtained by heating mesitylene with PH_3 at 280° (Baeyer, Z [2] 5, 320, A 155, 273). Oil, smelling like petroleum. Converted by prolonged heating with fuming HNO_3 into tri-nitro-mesitylene.

MESITYLENE SULPHINIC ACID
 $C_6H_3Me_3SO_2H$ [1 3 5 6] [99°]. Formed by adding a mixture of sodium amalgam and $C_6H_3Me_3SO_2Cl$ to a dry mixture of benzene and toluene, and decomposing the resulting pulpy mass with HCl (Holtmeyer, Z 1867, 686). Fan-shaped groups of needles -- BaA' , aq -- AgA' .

MESITYLENE SULPHONIC ACID $C_6H_3Me_3SO_3H$ [*c* 77°]. Formed by dissolving mesitylene in warm H_2SO_4 (Hofmann, C J 2, 113, Jacobsen, A 146, 85, 184, 185, Beilstein a Kögler, A 137, 317, Fittig, J 1866, 610, Z [2] 4, 583). Trimetric six-sided tables (containing 2aq) (Rose, Z [2] 6, 341, A 164, 53, Bodewig, J 1879, 737). Decomposed by distillation with dilute H_2SO_4 into mesitylene and H_2SO_4 , the hydrolysis beginning at 100° (Armstrong a Miller, C J 45, 149). Gives mesitol on potash-fusion (Jacobsen, A 195, 265).

Salts -- KA' , aq . Roundish groups of silky

laminae S 14 at 13° -- NH_4A' , aq [250°]. Plates, *v* sol water and alcohol -- CaA' , $5aq$ efflorescent crystals -- BaA' , $9aq$ S 6 6 at 18°, 5 5 at 11 5° -- SrA' , $7aq$ -- MgA' , $6aq$ -- CoA' , $6aq$ flesh coloured laminae, *v* sol water and alcohol. -- CuA' , $4aq$ Pale green laminae S 6 at 10° -- PbA' , $9aq$ Pearly plates S 15 at 20°.

Chloride $C_6H_3Me_3SO_2Cl$ [57°]. Wedge-shaped tables (from ether), insol water, *v* sol alcohol and ether (Holtmeyer, Z 1867, 686).

Amide $C_6H_3Me_3SO_2NH_2$ [142°] S 033 at 0°, 54 at 100° S (83 p.c. alcohol) 5 5 at 0°, 114 at 78°. Fibrous mass (from alcohol) or hair like needles (from ether). May be oxidised to $C_6H_3Me_3(CO_2H)_2SO_2NH_2$ and an acid $C_6H_3Me_3(CO_2H)_2SO_2NH_2$, and the anhydride of

an isomeric acid $C_6H_3Me_3\langle\frac{SO_2}{CO}\rangle NH$ (Hall a.

Remsen, Am 2, 130, Emerson, Am 8, 268).

Imide $(C_6H_3Me_3SO_2)_2NH$ [124°]. Formed by heating the amide with a little HCl in a sealed tube. Long needles, *m* sol hot water, sol $NaOH$ aq , and reppd by HCl .

Mesitylene disulphonic acid $C_6HMe_3(SO_3H)_2$. Formed by dissolving mesitylene (1 pt) in fuming H_2SO_4 (10 pts) and adding P_2O_5 (3 pts), the temperature being kept low during the operation (Barth a Herzog, M 1, 807). Deliquescent needles. Gives oxy-mesitylenic acid on potash fusion -- K_2A'' , $2aq$ -- NaA'' , $1\frac{1}{2}aq$ needles -- BaA'' , $3aq$ needles -- CuA'' (dried over H_2SO_4) greenish white needles.

Reference -- BROMO-MESITYLENE SULPHONIC ACID.

MESITYLENIC ACID $C_6H_3O_2$, *ie*

$C_6H_3Me_3CO_2H$. Di-methyl benzoic acid. Mol w 150 [166°] $H C v$ 1,084,300 $H C p$ 1,085,200 $H F$ 105,800 (Stohmann, Kleber, a Langbein, J pr [2] 40, 135). Colourless plates.

Formation -- 1 By boiling mesitylene with dilute HNO_3 (1 vol of SG 14 and 2 vols water) for 18 hours. The product is distilled with steam, boiled with a little tin and HCl aq to remove a nitro compound, and crystallised from alcohol (Fittig, A 141, 144, Fittig a Brückner, Z [2] 4, 493, A 147, 45) -- 2 By boiling *s*-dimethyl ethyl-benzene with nitric acid (SG 1.1) (Jacobsen, B 7, 1430, Wroblewsky, B 9, 495). 3 By passing CO over a mixture of $NaOEt$ and $NaOAc$ at 205°, or by heating such a mixture with zinc dust (Geuthner a Fröhlich, A 202, 310).

Properties -- Monoclinic crystals (from alcohol), *v* sol water, *v* sol alcohol. Sublimes below its melting point. Distillation with lime yields *m*-xylene. Chromic acid mixture oxidises it to trimelic acid.

Salts -- NaA' (dried at 130°). *V* sol water and alcohol -- CaA' , $\frac{1}{2}aq$. Not more soluble in hot than cold water -- BaA' , silky prisms -- MgA' , $5aq$ groups of monoclinic prisms -- ZnA' , (dried at 130°) laminae or needles, *sl* sol water -- MnA' , $-NaA'$, (dried at 130°) -- AgA' , Minute needles, *sol* hot water -- AgA' , aq (Hall a Remsen, Am 2, 130).

Ethyl ether EtA' (241°). Heavy oil; solidifies below 0°.

Amide $C_6H_3Me_3CONH_2$ [133°]. Needles; *v* *sl* sol cold water.

R_∞ 49.7 (Kanonnikoff, *J pr* [2] 31, 352)

Formation—1 One of the products of the action of H₂SO₄ on acetone (Kane, *P* 44, 476)
2 Together with phorone by leaving acetone for several weeks in contact with quicklime (Fittig, *A* 110, 32)—3 One of the products of the action of ZnEt₂ or ZnMe₂ on acetone (Pawlow, *B* 9, 1311, *A* 188, 130)—4 In small quantity, together with other bases, by distilling diacetone amine (Heintz, *A* 174, 133, 181, 70, *B* 8, 89)—5 By boiling with lime the lactonic products of condensation of acetoacetic ether (Hantsch, *A* 222, 21)—6 By boiling acetyl chloride with acetone (Beilstein a Wiegand, *Bl* [2] 38, 167)—7 Among the products of the distillation of glycerin with BaO (Destrem, *A Ch* [5] 27, 5)

Preparation—Acetone is saturated with HCl and then left to itself for a fortnight. The product is mixed with water, and the heavy oil, containing hydrochlorides of mesityl oxide and phorone, decomposed by alcoholic or conc aqueous KOH, and distilled with steam. The product is fractionally distilled (Baeyer, *A* 140, 297)

Properties—Oil, smelling like peppermint, insol water, miscible with alcohol and ether

Reactions—1 Boiling dilute sulphuric acid forms acetone. Conc H₂SO₄ gives mesitylene (Claisen, *B* 7, 1168)—2 Boiling dilute nitric acid yields acetic and oxalic acids—3 KMnO₄ oxidises it to acetic and oxy isobutyric acid (Pinner, *B* 15, 591)—4 Slowly combines with NaHSO₃ forming NaC₆H₃SO₃aq, the sodium salt of methyl isobutyl ketone sulphonic acid CH₃COCH₂OMe, SO₃H, which is decomposed by conc NaOH aq regenerating mesityl oxide (Pinner, *B* 16, 1727)—5 Bromine acts violently. But when it is added to a solution of mesityl oxide in CS₂, only C₆H₃Br₂O is formed. This can be distilled with steam, but in the dry state soon gives off HBr—6 A solution in dilute alcohol is strongly attacked by sodium amalgam and water then ppts a heavy oil C₆H₃O 'mesitic ether' or 'mesitic camphor' (c 215°) smelling like camphor. A small quantity of a solid [110°-120°] is also formed (Claisen, *A* 180, 7)—7 PCl₅ forms 'mesityl chloride' C₆H₃Cl₂, which separates on adding water as a heavy oil, smelling like oil of turpentine. It resinifies on exposure to air, and is decomposed by distillation over KOH, baryta, or lime into HCl and C₆H₃Cl, a liquid (130°) smelling like turpentine—8 Anmonia forms diacetoneamine C₆H₃NO—9 Hydriodic acid forms a heavy oil C₆H₃IO decomposed by alcoholic KOH into HI and mesitylene (Pawlow, *A* 188, 138)—10 HCl passed into a mixture of mesitylene and benzoic aldehyde forms C₆H₃COOHCHPh (Claisen a

Claparède, *B* 14, 849)—11 With acetamide and ZnCl₂ it forms oxy-tri methyl pyridine dihydride (Canzoneri a Spica, *G* 14, 349, *B* 19, 818, cf Engler a Riehm, *B* 19, 40)—12 With amyl nitrite and alcoholic NaOEt it forms the nitroso-derivative CMe, CH CO CH NOH, crystallising in colourless prisms [102°] (Claisen a Manasse, *B* 22, 529)

Oxim C₆H₃NO (c 185°) Formed by the action of hydroxylamine on mesityl oxide (Nageli, *B* 16, 495) Oil. Sol alcohol, ether, benzene, CS₂, ligroin, alkalis and acids. On warming with acids it is resolved into its constituents

MESOCALPHORIC ACID *v* CAMPHORIC ACID**MESORCIN** *v* TRI-METHYL RESORCIN**MESOTARTARIC ACID** *v* TARTARIC ACID**MESOXALIC ACID** C₆H₃O₄aq

CO₂H CO CO₂H + aq or CO₂H C(OH), CO₂H (Petrieff, *B* 11, 414) Mol w 136 [115°] (Deichsel), [108°] (Böttger, *A* 203, 140), [120°] (Fischer)

Formation—1 Together with urea, by boiling alloxan or alloxanic acid with baryta. The resulting Ba salt is recrystallised and decomposed by H₂SO₄ (Liebig a Wohler, *A* 26, 298, Svanberg, *B J* 27, 165, Deichsel, *B* 1864, 587)—2 By treating amido malonic acid with iodine and water (Baeyer, *A* 131, 298)—3 By boiling di bromo malonamide CBr₂(CO NH₂), with precipitated Ag₂O (Freund, *B* 17, 782)—4 By boiling di bromo malonic acid with baryta water (Petrieff, *J R* 10, 72)—5 By heating caustic acid with concentrated aqueous lead subacetate (E Fischer, *A* 215, 283)

Properties—Very deliquescent prisms, melting without loss of aq. M sol alcohol and ether, v e sol water. Its concentrated aqueous solution decomposes above 80° into CO₂, glycolic, oxalic, and glyoxylic acid (Böttger, *A* 203, 138). With acetates of Ba and Pb it gives flocculent pps gradually becoming crystalline. In neutral solutions CaCl₂ and BaCl₂ give pps. It reduces hot ammoniacal AgNO₃.

Reactions—1 H₂S passed into an aqueous solution to which silver oxide has been added forms thio glycolic acid CH₂(SH)CO₂H and thio di glycolic acid (sulphido diacetic acid) S(CH₂CO₂H)₂ (Böttger)—2 Sodium amalgam acting on its dilute aqueous solution forms tartaric acid CO₂HCH(OH)CO₂H—3 Silver mesoxalate boiled with water yields CO₂, oxalic acid, and silver—4 Urea at 100° gives allantoin C₄H₆N₂O₃—5 Hydroxylamine yields the oxim which is identical with nitroso malonic acid

Salts—[A⁻ = C₆O₄]—(NH₄)₂A⁻ granular crystals turning red in air (Deichsel, cf Engel, *G R* 98, 628)—(NH₄)₂A⁻ aq. Obtained by evaporation *in vacuo* over H₂SO₄.—Needles (Petrieff)—Na₂A⁻ aq thin laminae, v sol water.—CaA⁻ aq white pp insol dilute acetic acid.—CaA⁻ 4aq (dried at 100°) (Petrieff)—BaA⁻ aq (dried at 110°). White crystalline powder, v sl sol water.—BaA⁻ 1/3 aq.—BaA⁻ (dried at 180°)—(HO Pb)₂A⁻ nearly insol water.—Ag₂A⁻ aq amorphous pp changing to minute needles. Explodes when heated

Ethyl ether Et₂A⁻ aq. From the silversalt and EtL. Oil.

Di acetyl derivative of the ethyl ether $(\text{CO}_2\text{Et})_2\text{C}(\text{OAc})_2$ [145°] From the ether (1 mol) and AcCl (2 mols) at 100° (P) Long needles Partially decomposed by fusion and by solution in water

Di acetyl derivative $\text{C}(\text{OAc})_2(\text{CO}_2\text{H})_2$ [180°] From $(\text{CO}_2\text{Et})_2\text{C}(\text{OAc})_2$ and dilute alcoholic KOH Needles Its alkaline salts are v sol water, its silver salt $\text{Ag}_2\text{C}_4\text{H}_4\text{O}_8$ is an insoluble powder

Amide $\text{C}(\text{OH})_2(\text{CONH}_2)_2$ Deliquescent tables, which turn red in the air

Phenyl-hydrazide

$\text{PhHN}_2\text{C}(\text{CO}_2\text{H})_2$ [158°-164°] From mesoxalic acid and phenyl hydrazine hydrochloride in dilute acid solution (Elbers, A 227, 355) Crystals

Phenyl hydrazide of the Nitrile

$\text{PhHN}_2\text{C}(\text{CN})_2$ [185°] May be formed from the oxim phenyl hydrazide of glyoxylyl cyanide $\text{HO N CH C}(\text{N}_2\text{HPh})\text{CN}$ by dissolving in POCl_3 , heating with PCl_5 , pouring into ice, and treating the crystals with ether and alkali (Von Pechmann & Wehsarg, B 21, 3001) Yellow needles (from ether ligroin) Turns brown at 126° Sol hot water, alkalis, and the usual menstrua Conc H_2SO_4 forms a blood red solution not changed by FeCl_3 On warming with conc HClAq it forms yellow needles of $\text{C}_8\text{H}_5\text{N}_3\text{O}$ [215°]

MESOXALIC ALDEHYDE CHO CO CHO

Oxim HON CH CO CH NOH or

$\text{ON CH CO CH}_2\text{NO v Di NITROSO ACETONE}$

Mesoxalic semi aldehyde $\text{*CHO CO CO}_2\text{H}$ *Glyoxylyl carboxylic acid*

Diphenyl hydrazide

$\text{CH}(\text{N}_2\text{HPh})\text{C}(\text{N}_2\text{HPh})\text{CO}_2\text{H}$ [203°] From di bromo pyruvic acid in aqueous solution and phenyl hydrazine hydrochloride (Nastvogel, A 248, 87) Reddish yellow needles (from hot alcohol), almost insol water, sl ether and chloroform, v sol hot alcohol, acetone, benzene and HOAc Dyes wool and silk yellow Cold conc H_2SO_4 forms a dark red solution from which it is ppt by water unaltered

Di p tolyl hydrazide

$\text{CH}(\text{N}_2\text{HC}_6\text{H}_4\text{Me})\text{C}(\text{N}_2\text{HC}_6\text{H}_4\text{Me})\text{CO}_2\text{H}$ [188°] Formed in like manner Golden needles (from benzene) Its alkaline salts are v sol hot, sl sol cold, water

Nitrile $\text{*CHO CO CN v Glyoxylyl cyanide}$

Mesoxalic bromo semi aldehyde

$\text{*CBrO CO CO}_2\text{H}$

Methyl ether of the oxim

$\text{CBrO C}(\text{NOH})\text{CO}_2\text{Me}$ [c 170°] From di methyl di bromo pyrrole di carboxylate and HNO_3 at -18° (Ciamocian & Silber, B 20, 2601) Crystalline, sol alcohol, m sol cold water, insol petroleum ether Decomposed by fusion and by boiling with water

MESOXALYL-UREA is ALLOXAN See also its compounds with METHYL ANILINE, NAPHTHYL AMINE, and PYRROLES

META Use of this prefix applied to inorganic compounds, for *Meta-acids* and *Meta salts* v the acids or salts to the name of which *Meta-* is prefixed Thus *Meta-phosphoric acid* will be found under **PHOSPHORIC ACIDS**, and *Meta stannates* under **stannates**, a subdivision of the article **TIN**.

Names of organic bodies beginning with 'meta' will be found under the word to which 'meta' is prefixed

METACETONE The mixture obtained by distilling sugar with quicklime, called metacetone by Fremy (A Ch [2] 59, 6), is composed according to E Fischer & Laycock (B 22, 101) of propionic aldehyde, di methyl-furfurane, and hydrocarbons

METACETONIC ACID An old name for **PROPIONIC ACID**

METALBUMIN v PROTEIDS, Appendix C

METALDEHYDE v ALDEHYDE

METALLIC ACIDS In the article **ACIDS** (vol 1 p 47, cf **CLASSIFICATION**, vol 11 pp 201, 202), it is shown that compounds of H with certain negative elements or groups of elements react with metallic oxides, hydroxides, and carbonates, in presence of water, to produce substances composed of metal, and the elements of the hydrogen compound excepting the H or a part of the H Such hydrogen compounds are called acids The negative elements which are found intimately combined with H in acids are fluorine, chlorine, bromine, iodine, oxygen, sulphur, selenium, tellurium, carbon always enters into the composition of those negative groups of elements which combine with H or with H and other elements to form acids Only a few acids are binary compounds, the greater number are compounds of H with two or three other elements, among which are always found at least one of the eight negative elements enumerated above, or at least one of the negative carbon containing groups of elements By far the greater number of the more stable and definite acids are composed of H combined with non metallic elements, but some acids have been isolated which are composed of H combined with metals and one or more of the eight strongly negative elements already enumerated, or one or more of the carbon containing negative groups of elements The following table gives the composition of most of those acids which contain metallic elements —

Metallic acids

H_2AsO_4	(H_2TiO_4)	$\text{H}_2\text{PtCy}_4\text{Cl}_4$

H_2CoCy_4	$\text{H}_2\text{Pt}(\text{NO})_4$	H_2HgI_4
H_2CoCy_3	$\text{H}_2\text{Pt}(\text{NO})_3\text{Cl}_2$	$(\text{H}_2\text{ZnCl}_4)$
(H_2AlO_4)	$\text{H}_2\text{Pt}(\text{SCy})_4$	$(\text{H}_2\text{Zn}_2\text{Cl}_4)$
	H_2PtCy_4	

The isolation of some of the acids in the fore-

going list is doubtful, these acids are placed in brackets. The compounds H_2AlO_3 and H_2ZnO_3 are also bracketed, because the reactions of these bodies show that they may be classed as feeble acids and at the same time as basic hydroxides.

An examination of the composition of the metallic acids shows that the reacting atomic aggregates of these compounds all contain a number of atoms of a negative element, or group of elements, which is larger relatively to the number of atoms of metal present. The accumulation of negative atoms so modifies the functions of the H atoms that these are replaceable by metals, and this notwithstanding the presence of the positive metallic atoms. The H of the metallic hydrogen-containing compounds H_2CrO_4 ($= Cr_2O_3, H_2O$) and H_2CrO_5 ($= CrO, H_2O$) is not replaced by metals when these compounds react with metallic hydroxides or carbonates, but when 4 atoms of the negative O are associated with one atom of Cr and 2 atoms of H, the H of this compound (H_2CrO_4) is distinctly acidic. The negative character, or acid forming character, of the groups CN and SCN is rendered evident by the number of acids which are formed by the union of these groups with H and metals.

If attention is paid to the general chemical characters of the metals which form acids it is seen that most of these metals occur in groups (using this term as it is used in the nomenclature of the periodic law) which also contain several distinctly non-metallic elements: thus Ti, Sn, and Pb belong to Group IV, which group contains C and Si, Cr, Mo, W, and U belong to Group VI, in which group also occur the negative elements O, S, Se, and Te, As, Sb, V, Nb, and Ta form part of Group V, which is distinctly negative in its general chemical character, and includes the markedly non-metallic elements N and P, I, e, Co, Ni, Au, and the Pt metals occupy a peculiar position in Group VIII (*cf* CLASSIFICATION, vol. i pp 203-210, also IRON ELEMENTS, this vol p 65).

Several salts exist which, on account of their methods of formation and general stability, are probably best regarded as derivatives of metallic acids that have not yet been isolated, among such salts may be mentioned the stannous and zirconic fluorides $M_2Sn(Zr)F_6$. Some chemists would class most, if not all, the double metallic haloid compounds as salts of metallic acids, *e.g.* $BiF_3, 3KF$ as the K salt of the acid H_3BiF_6 , $ZnCl_2, BaCl_2$ as the Ba salt of the acid H_2ZnCl_4 , and MgI_2, KI as the K salt of the acid $HMgI_2$ (*v.* especially Remsen, *Am* 11, No 5).

The consideration of those metal-containing compounds which are acids brings out the inadequacy of that classification which would divide the elements into two classes only, metals and non-metals, it also well illustrates the difficulties of chemical classification, as shown by the way in which the chemical properties of an element are modified according to both the nature and the number of other elementary atoms with which that element is combined (*cf* the article METALS in this vol and CLASSIFICATION in vol. i).

M M P M

METALLOIDS This name was at one time applied, most mistakenly, to the non-metallic elements. It is sometimes used to denote those elements which on the whole are non-metallic,

but yet closely approach the metals in some of their properties, As, Sb, Ti, V, Nb, Ta, for instance, are sometimes called metalloids. The term cannot be defined. There are certain elements which one chemist would class among metals, another would place with the non-metals, and a third would prefer to put into neither class, but call them metalloids.

M M P M

METALLURGICAL CHEMISTRY The chemical reactions utilised in metallurgy are divisible into two distinct classes, viz 'wet,' those which take place in aqueous solutions, and 'dry,' those which take place in furnaces, or their equivalent, at a relatively high temperature. The present tendency is more and more in the direction of combining these two methods, metals being now frequently extracted from their ores partly by wet processes and partly by dry processes.

The ore of any metal may be defined as a collection of mineral substances containing that particular metal in sufficient quantity to pay for its extraction on a commercial scale. Although each metallic element exists in nature in a great number of combinations, yet very few of these compounds occur in sufficient quantity to be of direct importance to the metallurgist, except in so far as they may tend to introduce impurities into the metal to be extracted.

Chemically, ores may be broadly divided into three classes, containing respectively—I NATIVE METALS, *i.e.* metals uncombined with any non-metallic element II SULPHIDES and ARSENIDES III OXIDES, *including carbonates and silicates*.

Class I NATIVE METALS A native metal may be separated from its ores in one of four ways (a) By LIQUATION. In order that this may be done it is essential that the metal be fusible at a temperature insufficient to cause the earthy portions of the ore to frit or agglomerate, *e.g.* Bi. (b) By fusing the ore, when the metal will sink to the bottom by reason of its high SG., *e.g.* Bi, Cu. (c) By dissolving the metal out by means of another metal, *e.g.* Au, Ag, Pt. These metals may be dissolved out of their ores by Pb, which is then removed by cupellation, or, in the case of Ag, the separation of the Ag from the Pb may be effected by Zn, which does not alloy with Pb, and being specifically lighter rises to the surface, carrying the Ag and some lead with it. The Zn is subsequently distilled off, and the residual Ag and Pb cupelled. Similarly, Au and Ag may be dissolved out by Hg, which may then be distilled off. (d) By dissolving the metal by means of an acid or a gas in solution, *e.g.* Au extracted by a solution of Cl, and Pt, Pd, Ir, Rh, and Ru by *aqueous regia*. The Au and Pt may be refined by wet processes, taking advantage of the fact that Au and Pt are insoluble in sulphuric, hydrochloric, and nitric acid, when these acids are used separately, but are soluble in *aqueous regia*, while the Ag, Cu, Pb, and Fe are freely soluble in one or other of the three acids named. In 'parting' Au, sufficient Ag must be present to allow the acid free access to the impurities, which would otherwise be protected by the insoluble gold. Pt, when present in Au only in small quantity, may be separated by 'parting' with Ag, as under these conditions the Pt is

acted on by the 'parting acid' If present in larger quantity, it must be ppd from a solution. Ir may be separated from Au by difference of SG, and from Pt it may be removed to a certain extent by using *aqua regia* of medium concentration, in which it is not freely soluble. Pt is ppd from its solutions as a double salt of Pt and NH₃, by adding NH₄Cl. Pd, if present, may be ppd before the Pt by neutralising with Na₂CO₃Aq and adding HgCy₂. Ir, if it has gone into solution, will not be ppd with the Pt, but its double salt is difficult to wash out. Pd, Rh, Ru, and Os will also be found with the Ir in solution after the Pt has been ppd. Rh may be removed completely by fusing the platinum double chloride with KHSO₄, and a small quantity of NH₄H₂SO₄. Ir may be ppd at the same time as platinum by KCl, and the pp fused with K₂CO₃, which will oxidise the Ir and not the Pt. Remove the potassium salt by boiling water, and then dissolve out the platinum with *aqua regia*, in which the oxide of Ir is insoluble. Ir may also be separated from the pp by KCy, the Ir salt being soluble while the Pt salt is insoluble. Pt is obtained in the metallic state by carefully heating the double chloride, which then breaks up. Au is ppd from its solutions as metal by FeSO₄Aq, SO₂Aq, or H₂C₂O₄Aq. For dental purposes, Au is frequently deposited by electrical means. Ag is first thrown down as chloride, which is afterwards reduced by Cu, Zn, or Fe. Au, containing not more than 10 p.c. Ag, is also refined by Miller's process, at the Australian Mint, in the dry way, by passing Cl into the molten gold. The impurities As, Sb, Bi, Pb, and Zn are converted into chlorides, which volatilise, and the Ag becomes AgCl, which forms a fused layer on the surface of the gold.

Class II. SULPHIDES AND ARSENIDES. Dry methods. Sulphides and arsenides are either (a) *infusible*, at such temperatures as can be obtained in furnaces on the large scale, (b) *fusible*, or (c) *volatile without fusion*.

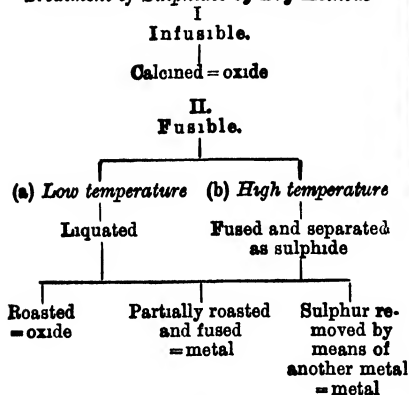

(a) *Infusible sulphides*. In these cases the S must be replaced by O, as an infusible sulphide cannot be properly reduced to the metallic state. This is done by calcining or roasting the ore, so that air has free access to it. The sulphide is oxidised to a sulphate at low temperatures, and at higher temperatures the sulphate breaks up into SO₂ and an oxide of the metal. Practically there is only one sulphide under this head, viz ZnS, *sinc blende*. For the subsequent treatment of the oxide see 'oxide class'.

(b) *Fusible sulphides*. Sulphides and arsenides of this class may be subdivided as follows—(i) *those which are fusible at a very low temperature, insufficient to produce fritting, & incipient fusion causing agglomeration of the constituents of the ore*, (ii) *those requiring a higher temperature, at which fritting would take place*. A sulphide in division (i) may be liquated out, e.g. Sb₂S₃. The sulphides and arsenides belonging to (ii) may be separated by fusing the ore, when the sulphide or arsenide would collect together beneath the slag, e.g. sulphide of copper (*copper pyrites*), arsenides of nickel and cobalt (if sufficient arsenic is not present in the ore more is added), the arsenide separates in a distinct layer from the sulphides of other metals during the

fusion, sulphide of nickel obtained by fusing nickel ores, or products, free from arsenic, with iron pyrites. The sulphides and arsenides thus separated from the gangue would next be treated in one of the following ways—1 *Converted into oxide by roasting*, e.g. Sb₂S₃, *copper matte*, arsenides of nickel and cobalt (the arsenious acid being condensed in coke towers), sulphides of nickel and cobalt free from arsenic, the oxides of nickel and cobalt are subsequently treated in the wet way. 2 *Partially roasted to form a certain amount of oxide and sulphate, and then fused*, the oxygen of the oxides combines with the sulphur of the sulphides and arsenides, forming SO₂, and liberating the metal, e.g. Sb₂S₃ and PbS. In the case of the double sulphide of Cu and Fe, the Fe is first removed by a series of calcinations and fusions, S passing to the Cu and O to the Fe, the oxide of iron thus formed uniting at the same time with silica to form slag. This process goes on so long as any iron remains. As soon as the iron is all removed, the reaction between Cu₂S, CuO, and Cu₂O takes place, liberating metallic copper. The principal impurities in copper ores likely to pass into the Cu are As, Sb, Zn, Pb, Bi, Sn, Ni, Co, Au, and Ag. The greater proportion of these present either volatilises or becomes oxidised and removed in the slags. Au and Ag, being neither appreciably volatile under the conditions nor oxidisable, become concentrated in the copper. It is particularly difficult to get rid of the last traces of As and Bi. The use of a basic lining to the furnace—say, dolomite—greatly facilitates the removal of As in the slag. The elimination of As is also assisted by the use of 'soda nitre' in refining. Bi can most readily be removed by what is known as the *best selecting* process, in which advantage is taken of the circumstance that copper has a greater affinity than bismuth for sulphur. This process comes in just before the copper is first reduced from the sulphide. A little copper is made to separate by the reaction between sulphide and oxide, this throws out and collects as 'bottoms' the bismuth, tin, lead, and antimony—3 *Fused in the presence of another metal which combines with, and so removes, the sulphur*, e.g. sulphides of Bi, Pb, and Sb treated with Fe, Ag separated by metallic Pb from sulphide of Pb containing sulphide of Ag. Copper can only be partially separated from sulphur in this way, a double sulphide forming which cannot be reduced by iron.

The operations described under (i) and (ii) are in some cases applied directly to the ore without first separating the sulphide by liquation or fusion.

(c) *Sulphides volatile without fusion*. Amongst the metallic sulphides there is only one which sublimes without fusion, viz HgS. When heated in presence of air HgS yields SO₂ and Hg. As the Hg has no tendency to combine with oxygen under these conditions, and is volatile at a very low temperature, it distils over, and may readily be condensed. For these reasons advantage is not taken of the fact that the sulphide is itself volatile, it being simpler to distil the metallic mercury direct from the ore. The sulphur is sometimes removed by roasting the mercury ore with lime or oxide of iron.

Treatment of Sulphides by Dry Methods**III.**

Sublimed without fusion

- 1 Sulphur separated by calcination alone = metal
- 2 Sulphur separated by lime, oxide of iron, or iron = metal

Wet processes for sulphides and arsenides. The sulphide and arsenide ores of Ni, Cu, and Co are partially, and those of Cu and Ag partially or wholly, treated by wet methods. In these processes the metal is first made to form a soluble compound. This may be done by roasting the ore with, or in some cases only mixing it with, some compound, which by double decomposition will convert the metal to be extracted into a soluble compound. In other cases it is done by roasting the ore alone at a low temperature, or even by simply exposing it to the action of the atmosphere without using artificially produced heat, in either case the sulphide will be converted into a sulphate, *e.g.* copper pyrites and silver ores.

Thus, soluble sulphate of copper may be formed by roasting copper pyrites or more slowly at the ordinary temperature of the atmosphere. About one third of the copper extracted in this country is obtained from Spanish pyrites, averaging only 3-4 p.c. of copper, by roasting the burnt ore—received from the sulphuric acid works—with common salt, which reacts with the CuSO_4 produced during the burning, to form CuCl_2 , which is then dissolved out, together with the chlorides of Ag, Pb, and Au, these metals being present to a small extent. The Ag is thrown down, along with Au and Pb, by a soluble iodide, KI or ZnI_2 . The iodine is removed from the AgI by Zn . Finally the Cu is pptd by addition of iron.

The reactions which take place in the wet treatment of silver ores are of special interest and importance. They are divisible into three classes.

I *The insoluble silver compound is decomposed and the Ag amalgamated while still in the ore ('free milling ore'), without the aid of any furnace-operation whatever.* If there is much S or As present the ore, where practicable, is first roasted with salt. Under this head are included all the amalgamation-processes.

II. *The insoluble silver compound is converted*

into sulphate by roasting alone and washed out with water, or the Ag is converted into chloride by roasting with common salt, and washed out by a solvent for chloride of silver. Under this head are included the Augustin, Ziervogel, Von Patera, and Russell processes.

III *The insoluble silver compound is converted into a soluble compound by the action of certain salts in solution without roasting the ore or employing any furnace-operation whatever.* This class includes the Von Patera process when applied to 'amalgamation tailings,' and the Russell process applied to both ores and tailings.

The amalgamation methods without roasting have been of great service where fuel is scarce, as in Mexico. These methods depend on the power of certain salts, such as the chlorides of Cu, to decompose Ag_2S . If mercury is present at the same time, the AgCl will be reduced and the Ag taken up by the excess of Hg, from which it can be separated by squeezing and distillation. Iron or Cu may be employed to decompose the AgCl , Hg being used only to collect the Ag. This reduces the loss of Hg, but to bring about sufficient contact, more power, and consequently more fuel, is required. Where fuel is available there is often great advantage in roasting the ore with salt before amalgamation.

Where possible the amalgamation methods have been superseded by the other wet processes included under heads II and III, viz the Augustin, Ziervogel, Von Patera, and Russell methods.

The Augustin process. Ore or regulus is first partially roasted, and then undergoes further roasting with common salt, the AgCl thus formed being washed out with NaClAq and pptd by Cu. The Ag is usually first concentrated in copper mattes.

The Ziervogel process. This method depends on the difference between the temperatures required to break up the sulphates of different metals. Thus by suitably regulating the temperature, the sulphates of Fe, Cu, &c., formed by roasting mattes at a low temperature, may be decomposed into oxides and SO_2 , while the sulphate of Ag will be unaltered, and can therefore be extracted by warm water, and then pptd as in the previous method. The regulation of the temperature throughout a large furnace is obviously a point requiring considerable skill. For this reason, in practice, mattes are usually first worked by the Ziervogel process, and the residue extracted by the Augustin method.

Von Patera process. The soluble salts produced by roasting the matte are first dissolved out with water, after which the matte is further roasted with NaCl , and the AgCl washed out with $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ or $\text{CaS}_2\text{O}_3\text{Aq}$, from which solution the Ag is pptd by a soluble sulphide or SH_2 . The silver is reduced from the Ag_2S , either by roasting or by boiling with freshly slaked lime, forming calcium polysulphide. When there is much of the base metals present, more particularly lead, the Von Patera process is not so suitable. The lead is mostly present as sulphate after roasting, and this is soluble in $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$. Some of the most important objections to the Von Patera process, as applied to poor ores containing base metal, are obviated in the process next described.

The Russell process In this process what is known as the 'extra solution' is used, in addition to or in substitution for that ordinarily employed in the Von Patara process. The 'extra solution' is prepared by making solutions of $\text{Na}_2\text{S}_2\text{O}_3$ and CuSO_4 , containing respectively 18 parts of the former and 10 parts of the latter salt, and mixing them together. The pp after washing is dissolved in a solution containing 1-2½ p.c. $\text{Na}_2\text{S}_2\text{O}_3$. Although this 'extra solution' is not so good a solvent for AgCl as $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$, yet it acts energetically on native silver and the compounds of silver with S, As, and Sb. Owing to the want of permanence special precautions have to be taken in using this solution. To get the best effect the solutions should be used warm. In order to obtain finer bullion by this process, advantage is taken of the fact that PbCO_3 is not soluble in the solution, although other salts of lead are soluble. Na_2CO_3 , free from NaOH and Na_2S , is added to the solution containing the silver and lead which have been washed out. It is stated that the whole of the Pb may thus be removed. Carbonate and sulphate of Cu are the only compounds of Cu likely to occur which are soluble in the 'extra solution'.

It is probable that this process in the near future will supersede very largely the fusion and amalgamation processes, besides which it is applicable to ores which cannot profitably be treated by either of the other methods. The cost of the necessary chemicals is much less than that due to loss of mercury, in addition to which, lead and copper are lost in the older processes and saved in the Russell process.

In some cases the ores may be treated direct by the Russell process without previous roasting, and both the Von Patara and Russell methods are largely used in the treatment of 'tailings' from amalgamation.

Nickel and cobalt It has been seen that these metals may be separated from others as arsenide. In practice, however, the separation is not so complete, some of the nickel and cobalt passing into the regulus, and some of the other metals into the speise. The following are the reactions usually employed to separate the various metals from one another. The calcined speise is treated with HClAq . The resulting solution, which will contain Ni, Co, Fe, Cu, Pb, Bi, and As, is diluted, and oxidised by bleaching-powder, the proportion added being adjusted by a rough analysis. Milk of lime is added to the requisite extent to throw the iron down as sesquioxide, any arsenic present at the same time ppg as basic arsenate of iron. The solution is next treated with SH , to ppt Cu, Pb, and Bi, after which the Co can be thrown down as sesquioxide by a further addition of bleaching-powder, and subsequently the Ni ppt as hydrated oxide by the addition of milk of lime.

Class III. OXIDES, INCLUDING CARBONATES AND SILICATES Ores of this class are reduced to the metallic state by means of carbonaceous matter such as charcoal, coal, or co's, or by means of the gaseous product of the incomplete oxidation of carbonaceous matter, viz carbon monoxide.

The only exceptions among the oxides of the commoner metals are Al_2O_3 and MgO . These oxides cannot be reduced to the metallic state in this way; they have to be converted into

double chlorides, from which, while in a state of fusion, the metals are liberated by metallic sodium, or by electrolysis. The metals, the oxides of which are in practice reduced by carbon or CO, are Sn, Fe, Ni, Co, Mn, Cr, W, and Zn. Of these Sn and Zn present the simplest reactions. The reactions in the other cases are complicated by the fact that all these metals combine more or less freely with carbon. When it is desired to obtain the metals in the most malleable condition, + e free from carbon, the fact that the oxides and the carburised metals react with one another eliminating both the carbon and the oxygen, as CO and CO_2 , is utilised. Every iron- and steel making process is dependent on this reaction. According as the conditions are made more or less favourable to carburisation, or decarburisation, so will the resultant metal be either cast iron, hard steel, mild steel, or malleable iron. It is possible to reduce the oxides under consideration to the metallic state, and also to carburise the metals, by the action of CO, without the metals becoming fused. The oxides are first reduced, and then carburised by the dissociation of some of the CO. The liberated oxygen combines with CO and is thus removed. Nickel is thus reduced to the metallic state, more or less combined with carbon, and bars of metallic iron are carburised to produce 'cementation' steel. In a similar way a carburised metal may be decarburised by O or CO_2 , in this way 'malleable cast iron' is made. Whether the action consists of carburising or decarburising is entirely dependent on which agent preponderates at the time in the atmosphere surrounding the body.

Reactions for removal of 'impurities' from metals of oxide class The refining of Ni and Co, as we have seen, precedes the reduction to the metallic state. The refining of Sn is effected after reduction, partly by liqation and partly by oxidation, by which means the principal impurities, Fe, As, and W, are removed. Mn and Cr are reduced directly from their ores, in the form of alloys with iron, only pure ores being used. Tungsten is either reduced directly from the ore, alloyed with iron, or undergoes a preliminary purification and ppg as oxide in the wet way. The impurities which it is important to remove from iron are S and P. The latter can only be passed into the slag when the slag is basic, and the conditions tend to oxidation. Thus, P is removed in the primitive iron making processes, also when iron is made by the 'finery' and the 'puddling' processes, also in making 'ingot-iron' by the Siemens and Bessemer processes, when a basic lining to the furnace or converter is used. P is not removed in processes in which pig iron or high carbon steel is made, nor in the Siemens or the Bessemer processes when the furnace or converter is lined with siliceous material, and malleable metal is being produced. In the Bessemer process, with an 'acid lining,' the necessary heat for the process is obtained mainly by the oxidation of silicon in the pig-iron, when a phosphiferous pig iron is used, and a 'basic lining,' most of the heat is obtained by the oxidation of the phosphorus and less silicon is required in the pig-iron. In both processes a portion of the heat is obtained from the oxidation of S. Sulphur can be removed econo-

mically only in the blast furnace, because when treating pig-iron for the production of malleable iron the sulphur is one of the last substances to oxidise out, and its removal would result in a great waste of iron. To remove S in the blast-furnace the temperature must be high, and the conditions must be strongly reducing and carburising: i.e. the charge must contain plenty of charcoal, coal, or coke, and lime must be added to the charge in considerable quantity. Under these conditions the S combines with the Ca, and passes into the slag as sulphide.

SLAG REACTIONS Slags consist of the non-metallic constituents of an ore or furnace product, and of the useless or objectionable metallic elements. They are produced by simply fusing the ore alone, if it is in itself sufficiently fusible, or by fusing it with such materials—fluxes—as will bring about the requisite fusibility. Except in a few special cases, e.g. the reduction of aluminium or magnesium, slags consist of more or less complex silicates. In processes for making more or less malleable iron, the slags are composed mainly of silicates of Fe, Ca, Al, and Mg, with smaller proportions of silicates of Mn, alkalis, and alkaline earths. In pig iron slags, the iron is comparatively small in quantity, or is even entirely absent when much lime is used. In other slags, excepting those produced in treating the 'noble metals,' iron will generally be present in large proportion.

ELECTRO METALLURGY Electro metallurgical processes are divisible into two distinct classes: one class includes processes for the extraction of metals from their ores, the other includes processes for refining metals already extracted. Although a great many processes have been devised for the electrical extraction of metals, except for the extraction of aluminium and magnesium—in which cases the metals are first got into the condition of double chlorides, or, in the case of aluminium, sometimes of fluoride—there is not much prospect of such processes being successfully and economically worked, even when power can be obtained from waterfalls. By the Cowles process, according to Sterry Hunt, nearly pure Al is produced in small buttons, but up to the present it has been necessary to reduce some other metal with the Al to collect it together. In this process the Al_2O_3 and the oxide of the metal to be alloyed with the Al are mixed with carbon, and the mixture is placed round two carbon poles between which an electric discharge is made to pass.

The second class of processes has been advantageously applied to the refining of Cu, more particularly Cu containing small quantities of Au and Ag. In refining Cu electrically, the electrolyte is usually $CuSO_4$, kept at as uniform a temperature and concentration as possible, the anode being formed of the copper to be refined, pure copper depositing on the cathode. The silver and gold collect at the bottom of the tank as a muddy deposit.

METALS. A K H
An element is a definite and distinct kind of matter which has resisted all attempts to separate it into unlike portions. The classification of the elements, in accordance with their chemical properties, necessarily carries with it the classification of many compounds, inasmuch as the chemical properties of an ele-

ment cannot even be stated without considering the composition, general chemical behaviour, and conditions of formation, of compounds of that element. For instance, certain elements are placed in the same class because they all form hydroxides which are alkalis: this statement implies an acquaintance with the composition, methods of production, and chemical properties, of the alkalis, but one of the chemical properties of an alkali is that it neutralises acids, and in so doing forms salts, hence it is necessary to know something about acids and salts, in order to understand what is meant by an alkali, or by an alkali forming element.

The elements may be classified in accordance with their physical properties. If a binary compound is electrolysed, one of its elements separates at the positive electrode, and the other at the negative electrode (secondary reactions which may occur are supposed to be overlooked). That element which separates at the positive electrode is said to be electro positive to the other element. By studying the electrolysis of binary compounds, the elements may be arranged in an electrical series. This series may be divided into two parts: all the elements on one side of any chosen element are electro positive to all the elements on the other side of the chosen element. Taking hydrogen as the central element we are able to subdivide the elements into two classes, all the elements on one side of H are electro positive to the elements on the other side of H. Thus we arrive at a classification of the elements founded on one chemical-physical property. Now we find that the electro-positive elements, on the whole, more resemble one another in certain physical properties, and also in their general chemical character, than they resemble the electro negative elements. Those elements which are electro positive to H as a class are greyish white in colour, lustrous, fairly malleable and ductile, comparatively good conductors of heat and electricity, those elements which are electro negative to H vary much in colour and appearance, they are not usually lustrous, they are generally brittle, and they do not conduct heat or electricity well. Turning to the chemical characters of the two classes of elements, we find that those placed in the electro-positive class generally combine with O to form basic oxides: their compounds with O and H are also usually basic, they do not, as a rule, enter into the composition of acids, very few of them form hydrides, their haloid compounds, as a whole, are tolerably stable as regards the action of heat, and they are not readily decomposed by water, if they are thus decomposed they generally produce oxyhaloid compounds, speaking broadly, these elements do not exist in allotropic forms. On the other hand, we find that most of the elements which are placed in the electro negative class combine with O to form acidic oxides, their compounds with H and O are usually acids. All acids contain one or more of these elements, they generally form hydrides, many of their haloid compounds are decomposed by heat, and many of them are also decomposed by reacting with water, thereby producing haloid acids and either oxides or oxyacids of the electro negative elements; speak-

ing broadly, these elements exhibit the phenomena of allotropy

Hence, it would appear that the division of elements into two classes, those which are electro positive to H, and those which are electro negative to H, is a good classification, because with this one class mark many other properties, both physical and chemical, are associated

The electro positive elements are called metals, the electro negative elements are called non metals

A further examination of metals and non-metals shows that the classification implied in these terms is very far from being sufficient for chemical purposes. We cannot define the term metal, just as we cannot define any of the chemical names which are given to classes of bodies. We can sketch the ideal metal. Considered physically, the ideal metal is a hard, fairly heavy, greyish-white, lustrous, malleable, ductile, and tenacious solid, which melts only at a high temperature, it is a good conductor of heat and electricity, it crystallises in forms belonging to the regular system, its emission spectrum consists of lines, and is comparatively simple in character. Considered chemically, the ideal metal is hardly, if at all, changed in the air, it combines with O at fairly high temperatures, and forms one or more oxides which are basic, &c which react with acids to form salts, it reacts with water or steam to produce an oxide or hydroxide and evolve H, no hydride of the ideal metal is known, it does not enter into the composition of acids, but it reacts with acids to form salts, its sulphides react with acids to produce salts and evolve H₂S, they combine with the sulphides of decidedly electro-negative elements, the salts of the ideal metal are numerous and stable, it forms but few acid salts, but the number of double salts into which it enters is large, it combines directly with the halogens, producing compounds which are volatilised without decomposition at rather high temperatures, and which dissolve in water without change, the ideal metal forms alloys with elements of its own class, which alloys are long rather to the group of physical, than to that of chemical, compounds, lastly, the ideal metal exists in only one modification, &c it does not show allotropy. The ideal non-metal is the opposite, chemically and physically, of the metal

No element exhibits all the properties which we have placed in the category 'metal', nor is there any element which possesses even some of these properties without at the same time also possessing some of the properties which belong to the typical non metal

The elements sodium and potassium possess most of the chemical properties enumerated as characteristic of metals, but these elements are instantly oxidised by exposure to air, they probably form unstable hydrides, they are very soft, lighter than water, and melt at moderately low temperatures.

The element gold possesses most of the physical properties characteristic of metals, but its hydroxide reacts with alkalis to form salts, e.g. KAuO₂; Au also forms the acids H₂AuBr₂ and H₂AuCl₂; Au₂S combines with the sulphides of

VOL. III.

the very metallic elements K and Na to form salts. The element chromium exhibits many of the characteristic physical properties of metals, it also decomposes steam with evolution of H, it combines with the halogens to form stable compounds, some of which have been gasified at high temperatures, chromium does not form a hydride, the oxides CrO and Cr₂O₃ are basic, the element reacts with many acids to form salts, which are well marked, stable compounds, it does not exist in allotropic forms. On the other hand, CrO₃ is a distinctly acidic oxide, reacting with water to form the acid H₂CrO₄, from which is obtained a large number of salts. In other words, chromium belongs to the class metals, and also to the class non-metals. In an even more marked way than Cr, manganese combines in itself both metallic and non metallic properties

The chemical properties of an element depend on the properties of the other elements with which it combines, and on the relative quantities of these other elements entering into combination. It is this fact which makes it impossible to apply the definition of metal or non metal, in its entirety, to any element. The classification of elements into metals and non metals is nevertheless a useful one, provided it is employed with judgment and knowledge. If we find that a certain element is hard, lustrous, unchanged or only slowly changed in the air, and is a good conductor of electricity, or if we find that the oxide of a certain element is basic, and that the chloride is not decomposed by water, or if decomposed produces an oxychloride, we have at once a guide to lead us in our further examination of the element. We shall probably find that the element in question possesses several of the other physical characteristics of metals, and we shall also probably find that it reacts with acids to form salts, decomposes steam with evolution of H, produces at least one sulphide which combines with sulphides of some of the negative or non metallic elements, and so on

The following division of the elements usually placed in the class metals is that arising from the application of the periodic law

CLASS I division	1, Li Na K Rb Cs
"	2, Cu Ag Au
CLASS II division	1, Be Ca Sr Ba
"	2, Mg Zn Cd Hg
CLASS III division	1, Sc Yt La Yb
"	2, Al Ga In Tl
CLASS IV division	1, Ti Zr Ce Th
"	2, Ge Sn Pb
CLASS V division	1, V Nb D ₁ Ta
"	2, As Sb Er Bi
CLASS VI division	1, Cr Mo W U
"	2, none isolated.
CLASS VII division	1, Mn
"	2, none isolated.
CLASS VIII division	1, Fe Ni Co (Cu)
"	2, Rh Ru Pd (Ag)
"	3, Os Ir Pt (Au)

The metals in division 1 of Class I are generally known as the *alkali metals*. They possess in the most marked way the chemical characters of the ideal metal; none of their compounds exhibits any acidic functions, they are electro-positive to all the other elements. The metals

R

in division 2 of Class I are very distinctly metallic in their physical properties, chemically considered they show considerable differences among themselves, several compounds of gold are almost non-metallic in their reactions, the chemical and physical analogies of this element are best represented by placing it both with Cu and Ag, and also with Os, Ir, and Pt, in division 3 of Class VII.

The *alkaline earth metals* which form division 1 of Class II are more metallic in their physical properties than the metals placed in division 1 of Class I, chemically they are also distinctly metallic. Coming to Mg, Zn, Cd, and Hg, which form division 2 of Class II, we have four elements whose properties closely approach those of the ideal metal, Cd may be taken as on the whole the best actual representative of the class metal. As we pass to the higher classes we find many metals exhibiting properties characteristic of non-metals, until in Class VII we arrive at Mn, an element which is at once distinctly metallic and decidedly non-metallic in its chemical properties.

In connexion with the subject of this article, references should be made to the following articles wherein the different classes of metals are described — ALKALINE EARTHS, METALS OF THE, vol 1 p 112, ALKALIS, METALS OF THE, vol 1 p 114, CHROMIUM GROUP OF ELEMENTS, vol 11 p 168, COPPER GROUP, vol 11 p 250, EARTHS, METALS OF THE, vol 11 p 424, IRON GROUP, vol 11 p 65, MAGNESIUM GROUP, vol 11 p 163, NITROGEN GROUP (for Class V, V to Bi), vol 11 *infra*, NOBLE METALS, vol 11 *infra*, TITANIUM GROUP, in vol 14, TIN GROUP, in vol 14.

M M P M

METALS, RARE Under this name are included a number of presumed elementary bodies concerning which our knowledge is at present very imperfect. We see that in their general properties they approximate more or less closely to cerium, yttrium, and lanthanum, but we are not sure how far we have yet obtained them in a state of purity. Consequently we are in doubt not merely as to their at. w. and S.G., but even as to their number and their rank as elements, compounds, or mere mixtures. Our ignorance is due to the great rarity of these bodies, to the high complexity of the minerals in which they are found, but most of all to the fact that they differ among themselves merely by very minute shades.

The principal sources of the rare metals are *gadolinite*, *keilhauite*, *fergusonite*, *euxenite*, *cerite*, and *thorite*, which are Norwegian minerals, and further, *samarshkite*, which was first obtained from the Urals, but has since been found in relatively large quantities in North Carolina. It is to be noticed that specimens of any one of these minerals, if from different localities, are not identical in the earths they contain. Hence if it is desired to isolate any particular earth it is best to select as the first material that mineral in which nature has, so to speak, commenced the task of separation. (This method was proposed by the writer in his address to the chemical section of the British Association, Birmingham Meeting (*C N* 64, 128, *ibid* 54, 157, *Pr* 40, 505). Nilson and Krüss have since adopted and recommended the same method (*B* 20,

2134, *C N* 56, 74, 85, 135, 145, 154, 165, 172).

The recognition of the various rare earths is a matter of no little delicacy. Here spectroscopy in its several modifications renders the greatest service. In endeavouring to ascertain by this means what substances are present in a mineral containing rare earths, chemists may employ either the spark spectrum, the absorption spectrum, or the incandescence or the phosphorescence spectrum. They may further apply any of these tests either at once to the original matter, or to some of its portions after a partial separation has been effected by chemical treatment. The question of course arises, how are we to know when we have obtained any one earth separated from all other bodies, and absolutely pure? In the case of those earths and their solutions which present an absorption spectrum, *e.g.* didymia, samaria, holmia, erbia, &c., the writer has shown that as an element approaches simplicity the absorption spectrum of its solutions will become less and less complicated, hence it would appear that when absolutely free from its associates, each element would have an absorption spectrum of great simplicity, in many cases consisting of one band only (the 'one band, one element' hypothesis). But as certain earths, *e.g.* lanthana, mosandra, philippia, scandia, terbia, &c., give no absorption spectra, this test is not applicable in all cases.

Great caution is required in drawing conclusions from the examination of spectra. Concerning the influence of one body upon another little is yet known, but that little is of sufficient importance to make us very careful how we interpret absorption-spectra when not corroborated by chemical results. Lecoq de Boisbaudran and J. Lawrence Smith have pointed out some important modifications produced in absorption spectra by the presence of an excess of acid in the solution (*C R* 88, 1167). Soret subsequently verified these observations. Brauner and others have put on record experiments on mixing solutions of didymium and samarium. They find in the case of a didymium solution showing the group of three bands, 476, 469, 428 [$1/\lambda^2$ 430.4, 441.3, 454.6], that, by adding a dilute solution of samarium, these three bands vanish, without the appearance of any of the samarium bands, until a certain proportion is reached, when the samarium bands gradually come into their places (Brauner, *C J* 43, 286).

Many of the earths that do not yield solutions giving absorption spectra can be made to give characteristic spectra by phosphorescence. This is known as the 'radiant matter' test. When the spark from a good induction coil traverses a tube having a flat aluminium pole at each end, the appearance of the spark changes according to the degree of exhaustion. If atmospheric air is the gas under exhaustion, at a pressure of about 7 mm a narrow black space is seen to separate the luminous glow and the aluminium plate connected with the negative pole of the induction coil. As the exhaustion proceeds this dark space increases, until at a pressure of about 0.02 mm the dark space nearly fills the tube; the luminous cloud showing the presence of residual gas has almost disappeared, and the molecular discharge from the negative pole

begins to excite phosphorescence on the glass where it strikes the side. There is a very wide difference in the degree of exhaustion at which various substances begin to phosphoresce. Under the influence of this discharge of 'radiant matter,' a great many substances emit, more or less intensely, a phosphorescent light. On examining this light in the spectroscopic, most of these bodies give a faint, continuous, spectrum with a more or less decided concentration in some one part, the superficial colour of the phosphorescing substance depending on this preponderating emission in one or other part of the spectrum. Sometimes, but less commonly, the spectrum of the phosphorescent light is discontinuous.

If we examine the rare earths by this 'radiant matter' test we find they present phenomena of a striking character. Some of them remain unaffected, and are thus at once referred to a distinct group. Others, such as thoria, do not phosphoresce and offer great obstruction to the passage of the spark. Other earths become very phosphorescent and vary greatly in their power of retaining a residual phosphorescence. On examining phosphorescent earths glowing in a vacuum tube, the writer found remarkable differences in the duration of this residual glow. Some of the earths remain luminous for many minutes after the cessation of the current, while others cease to phosphoresce immediately on the stoppage of the current. Take the case of yttria. This earth, the writer finds, can be resolved by chemical treatment into a series of simpler bodies of unequal basicity, to which he has given the provisional designations of Ga, G β , G δ , G ζ , G η , and Sy. The after-glow of these bodies differs somewhat in colour from that which the earth exhibits while the current is still passing. The spectrum of the after glow also shows that some of the lines are missing. In the electrical phosphoroscope—an instrument similar to Becquerel's phosphoroscope, but having the substance acted on electrically instead of by direct light—the different bands of the new constituents of yttria (*in vitro*) do not all appear at the same speed of rotation. At the lowest speed the double greenish blue band of G β is first seen, followed next by the dark-blue band of Ga. As the velocity increases there follows the bright citron yellow band of G δ , and as the utmost speed approaches the red band of G ζ is seen, but not without difficulty. As another instance, if lanthanum sulphate, with traces of Sm as impurity, along with a little lime is examined in the phosphoroscope, the band of Ge is visible at the lowest speed, G δ follows at an interval of 0.035 second, and the Ga band immediately afterwards. All the earths of the yttrium and samarium groups yield discontinuous spectra when submitted to the induction discharge *in vacuo*.

A modification of phosphorescence spectroscopy is produced by the previous addition of other earths to the specially phosphorescent earths. Lime exerts a remarkable action. By itself, it phosphoresces with a continuous spectrum, while yttria phosphoresces with a discontinuous spectrum. But if these two bodies are mixed together, the phosphorescing energy of the lime does not extend over the whole spectrum,

but concentrates itself in strengthening the yttria bands. These bands become broader, but at the same time less sharply defined, in proportion as the lime is increased in quantity. Lime also brings out the phosphorescent bands of samaria. It also suppresses the sharp line S δ , the most striking feature in the phosphorescent spectrum shown by pure samarium sulphate. On the other hand an addition of 'old' yttria deadens the other lines of samaria, but brings out the line S δ more strongly. Lanthanum sulphate in the 'radiant matter' tube phosphoresces with a reddish colour. If lime is added to lanthanum sulphate the phosphorescence changes its colour from red to yellow. Lime also brings out the bands of yttrium and samarium if these are present as impurities. So sensitive is this test that it will show the presence of one part of yttria or samaria in more than a million parts of lime. When G δ , Ga, and G β are present in small proportions with lime the bands of G δ and Ga become intensified, but a dark space appears instead of the green band of G β . Hence if only a small trace of G β is present in lime the green band is not only obliterated, but the quenching action suppresses that part of the continuous lime spectrum which has the same refrangibility as the G β line, and thus gives a black space in the spectrum.

There are many instances of the modifications induced in the normal spectrum of one earth by the admixture of others when treated as anhydrous sulphates. One of the most striking instances is that of a mixture of samaria with yttria, since the presence of even 40 p.c. of yttria practically obliterates the spectrum of samaria. The most minute proportion of lime added to samaria causes the sharp line at $1/\lambda^2$ 269 to vanish, while at the same time it much intensifies the other bands (Tr, pt II, 1885, C R, June 15, 1885). The action of lime upon yttria is of great use in detecting very minute traces of this earth when in admixture with elements which would otherwise prevent its phosphorescence.

Alumina is also active in inducing new spectra when mixed with the rare earths. A moderate amount of fractionation has enabled the writer to penetrate beneath the veil of red phosphorescence observed in crude alumina and to see a complicated sharp line spectrum (C N, 56, 62, 72). The new body of which glimpses have been obtained is probably one of the unknown earths in decipia, since the new spectrum may be fairly reproduced by adding one of the fractionations of decipia to alumina. Hence, it will be seen that the performance of a long series of check and counter-check experiments often becomes necessary before the presence or the absence of any particular earth can be inferred.

The quantitative separation of the rare metals is much more difficult than their mere recognition. These substances are not linked to one another, or to other elements with which they are associated, by any strong affinities, but they are nearly identical in their behaviour and properties. Hence we have so far been unable to find any reagent or any mode of treatment which at once quantitatively separates one of these substances from all the others. We are therefore obliged to have recourse to tedious processes of fractionation.

In attempting to enumerate or describe the rare metals, we meet with the additional difficulty that the unitary character of many of them is still a matter of extreme doubt.

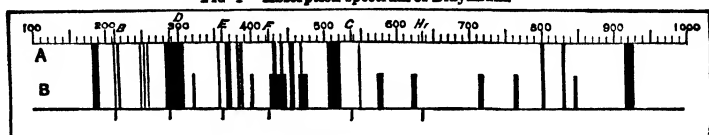

Several of the rare metals will be found described in their proper alphabetical order in this Dictionary, *e.g.* beryllium, cerium, didymium. Many of these, as will be seen below, are probably capable of being further split up, but as they are frequently mentioned in chemical treatises and memoirs their description as at present, or lately, known has been found necessary.

There are certain other metals which are still under discussion, *e.g.* decipium, philippium, holmium (Soret's X), and dysprosium. Roscoe has indeed proved that philippium is a mixture of terbium and yttrium, and the experiments of the writer have confirmed his results, but until we know more about the constitution of terbium and of yttrium, both of which are undoubtedly compound bodies, these experiments do not carry us much further. Samarium is also identical

separate a mixture of two bodies into two parts, just as the addition of a reagent only divides a mixture into two portions, a precipitate and a solution. These divisions will be effected on different lines according to the reagent employed. Thus, if we add ammonia to a mixture we may get a separation into two parts, but if we add oxalic acid to the same original solution we split up the mixture differently and obtain two other parts. Thus, if we crystallise a solution of old didymium, as was done by Auer von Welsbach, we divide its components into neodymium and praseodymium. But by fusing didymium nitrate we divide its components in a different way and obtain different products. Now, it is clear that so long as by different modes of attack we obtain different products, we have not yet reduced the original substance to its ultimate elements, we have not yet reached bed rock.

We find that a compound molecule may behave as an element, as has been shown in the case of old didymium. Chemists have a certain

Fig 1—Absorption-spectrum of Didymium.

The scale is $\frac{1}{\lambda}$

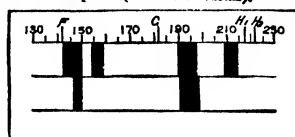

with a body which other chemists have named 'yttrium β '.

It has been mentioned elsewhere that the old didymium, after the elimination of Delafontaine's decipium, was found by Lecoq de Boisbaudran to contain another body, which he named samarium, characterised by the bands of Delafontaine's decipium, together with two additional bands (*cf.* figs 1 and 2). After the removal of these bodies the residual didymium was split up by Auer von Welsbach into the two bodies, neodymium and praseodymium, the absorption spectra of which are shown respectively in figs 3 and 4. It will be observed, however, that two of the bands of old didymium are not to be found in the neodymium and praseodymium spectra taken conjointly. Hence it becomes extremely probable that there exists a third body distinct from neodymium and praseodymium to which one of these extra bands, or possibly both, is due. This probable metal the writer has provisionally named D α . But we still encounter the question whether neodymium, praseodymium, and D α are ultimate elements, or are capable of still further scission. The researches of several investigators point very decidedly in the latter direction. Thus Nilson & Krüss in 1887 appear to have obtained from didymium no fewer than nine bodies, each of which may possibly prove to be an element. These bodies have been provisionally named by the discoverers D α , D β , D γ , D δ , D ϵ , D ζ , D η , D θ , D ι .

It seems to the writer that neodymium and praseodymium are simply the products into which the original didymium is split up by one particular mode of attack. Any single chemical operation, whether it be crystallisation, precipitation, fusion, partial solution, &c., can only

number of reagents, operations, or processes in regular use, and if a substance resists all these and otherwise behaves as a simple body, they call it an element. But for all this it may prove to be a compound. Hence, we may legitimately pause before conceding to neodymium and praseodymium the rank of elements. We need some criterion for an element which shall appeal to our reason more clearly than the old untrustworthy characteristic of having not as yet been decomposed, and to this point chemists would do well to turn their most serious attention.

Fig 2—Absorption spectrum of Samarium and Decipium (De Boisbaudran).

In samarium the writer, by means of the 'radiant matter' test, has recognised four bodies, named provisionally S β , G ϵ , G γ , and G θ . Very similar observations seem to prove that, like didymium and samarium, erbium, holmium, thulium, dysprosium, &c., are compounds or mixtures of a number of closely allied bodies.

In order to ascertain the existence of supposed new elements, chemists have proposed as a test that certain absorption-bands seen in different solutions follow the same variations of intensity. If this is the case we may infer that they are all characteristic of one and the same substance. But if one of the bands dies out while others remain unaltered we may judge that two or more distinct bodies are present.

In erbium the writer has detected two bodies, which he has characterised by their absorption bands $\lambda 550$ and $\lambda 493$. Krüss a Nilson apply apparently to the same bodies the names $\text{Er}\alpha$ and $\text{Er}\beta$. To obviate all confusion it must be remembered that the name 'erbia' has been given to two bodies which are not identical. The substance which ten years ago was called erbia, and which was then supposed to be the oxide of a simple metal, has been resolved by the investigations of Delafontaine, Marignac, Soret, Nilson, Clève, Brauner, and others into at least six distinct earths. Three of these—scandia, ytterbia, and terbia—give no absorption spectra, while three others—erbia (new), holmia, and thulia—give absorption spectra. The first to question the elementary character of old erbium was Delafontaine (*C R* 87, 559, *C N* 38, 202). He obtained from it and described philippia, a yellow oxide having a strong band in the violet ($\lambda 400$ to 405), a broad black absorption band in the indigo blue (about $\lambda 450$), two rather fine bands in the green, and one in the red.

The history of philippium is very instructive. Soon after Delafontaine's discovery, Soret (*C R* 89, 521, *C N* 40, 224) stated that he was unable to identify 'Soret's X' with Delafontaine's philippia, the latter being characterised by an absorption band in the blue occupying the same place as one of the erbia bands. In 1880 Delafontaine (*C R* 90, 221, *C N* 41, 72) described ten new earths as present in gadolinite and samarskite, viz., mosandra, philippia, ytterbia, decipia, scandia, holmia, thulia, samaria, and two others to which he did not assign names. He concluded that the properties of philippia were identical with those of Soret's X and of Clève's holmia, and proposed that the name holmia should be set aside in favour of philippia. In *C R* 91, 328 (also *C N* 42, 185), Clève repeated his earlier assertion that philippia was not identical with Soret's X or holmia. Delafontaine then withdrew all he had said about the absorption spectrum of philippium and decided that it had no absorption spectrum at all (*Archives de Genève* [3] 999, 15). Lastly Roscoe (*C J* 41, 277) gave an elaborate account of the earth metals in samarskite, proving philippia to be a mixture of ytterbia and terbia. The present writer, after prolonged chemical examination of these earths, has come to a similar conclusion, but a spectroscopic examination of the earth left on igniting some very carefully purified crystals of philippium formate, tested in the radiant matter tube, has shown that in the separation of Delafontaine's 'philippium' the ytterbia undergoes a partial fractionation.

Shortly after the announcement of philippium, Soret (*C R* 86, 1062) described an earth which he provisionally named X. It was subsequently found to be identical with Clève's holmia (*C R* 89, 479, *C N* 40, 125). The absorption spectrum of this earth is marked by a very strong band in the extreme red ($\lambda 804$), two characteristic bands in the orange and green ($\lambda 640$ and 536), with fainter lines in the more refrangible part of the spectrum, and a number of bands in the ultra violet (see fig 7). The claim of holmium to rank as an element has been disputed by Nilson and Krüss, who assert that it consists of, or at least contains, four distinct

bodies, provisionally named $\text{X}\alpha$, $\text{X}\beta$, $\text{X}\gamma$, $\text{X}\delta$. By submitting Soret's X to fractional precipitation, and examining the fractions spectroscopically, Lecoq de Boisbaudran found that this X, otherwise holmium, consisted of at least two elements one of these he has named dysprosium, reserving the name holmium for the residue left after the elimination of the dysprosium. The absorption spectrum of dysprosium shows four bands, $\lambda 451.5$, 475 , 756.5 , and 427.5 . The absorption spectrum of what may be called new holmium is shown in fig 8. What relation this new holmium bears to any of the components observed in the original spectrum of holmium by Krüss and Nilson is not as yet determined.

The writer (*Pr* 40, 502) obtained an earth by repeated fractionation, in which one of the bands ascribed to dysprosium, that namely at $\lambda 451.5$, was very strong, though the others were absent. As de Boisbaudran regards the bands $\lambda 475$ and 451.5 as both belonging to dysprosium, and as the earth obtained gives $\lambda 451.5$ strong but with scarcely a trace of $\lambda 475$, dysprosium consists of at least two simpler bodies. Krüss and Nilson in fact resolve it into three bodies to which they have given the provisional names $\text{X}\zeta$, $\text{X}\epsilon$, $\text{X}\eta$, and de Boisbaudran gives the absorption spectrum of dysprosium as shown in fig 9.

Simultaneously with the discovery of holmia, Clève announced the separation of a second earth from erbia, which he called thulia. Its absorption spectrum consists of a very strong band in the red $\lambda 680$ to 707 , and one in the blue $\lambda 464.5$ (fig 10). The ultimate character of thulium is by no means established. Krüss and Nilson resolve it into two bodies, $\text{Tm}\alpha$ and $\text{Tm}\beta$. Nevertheless the atomic weight of thulium has been determined as 170.7 , and the composition Tm_2O_3 has been assigned to its oxide, determinations which for the present must be regarded as premature.

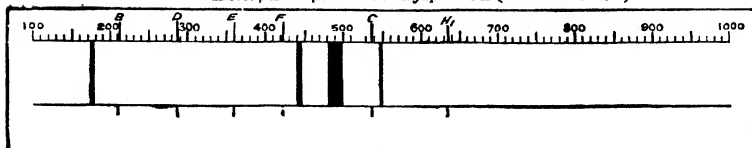

Further, it must be mentioned that the spectrum of old erbium has two faint bands, one at $\lambda 550$ and a second broader one at $\lambda 493$ (fig 11). These bands are not to be found in the spectrum of holmium, thulium, dysprosium, or the new erbium (fig 12). In a long continued fractionation of the erbia group of earths, conducted with an ample supply of the old erbia, the writer finds an earth giving these two bands concentrated at one end, the bands becoming stronger, while at the same time two other bands make their appearance. This phenomenon indicates the existence of another earth as yet unknown, belonging to the erbium group.

We next come to the yttrium group, comprising the metals yttrium, terbium, gadolinium, ytterbium, scandium, mosandrium, columbium, and rogerium. Of these yttrium, terbium, ytterbium, and scandium form the subject of distinct articles in this Dictionary.

Columbium and rogerium were discovered in the samarskite of North Carolina by J. Lawrence Smith in 1879, but nothing further has been published concerning them. This columbium is perfectly distinct from an element sometimes called columbium, but better known as tantalum.

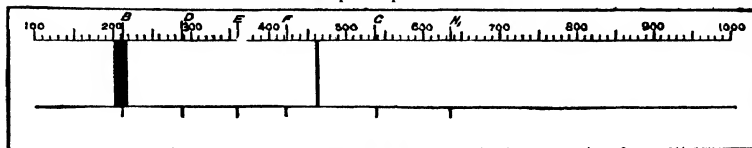

Mosandrium was also discovered by J. L. Smith, and has been the subject of a little controversy. Delafontaine pronounced it a mixture

of terbium, yttrium, erbium, didymium, and phosphorus. In November 1878 and in September 1879 Smith reasserted the elementary character of mosandrum. He states that its compounds are of a deep orange colour, that its double potassium sulphate is not easily soluble, and that its equivalent weight is 51.2. No recent and conclusive investigations on this alleged metal have appeared, and its existence must in the meantime be regarded as exceedingly doubtful.

Decipium has been considered as holding an intermediate position between the didymium and the yttrium groups of rare metals, but its elementary character is very questionable. It has not formed the subject of any recent researches. It is said to show a characteristic absorption band about λ 416.

Gadolinium, otherwise known as the Y_a of Magnac, gives no absorption-spectrum. In the writer's investigations its phosphorescence spectrum was found to consist of those of two of the constituents of yttrium, which will be mentioned below.

Yttrium proves to be an exceedingly complex substance. The body to which all chemists would have applied the name yttria as recently as four years ago may be split up into possibly six, but certainly five, bodies, G_a, G _{β} , G _{δ} , G _{ϵ} , and G _{γ} , two of which, G _{β} and G _{ϵ} , are also met with as the components of gadolinium. Hence it is convenient to speak of the original substance as 'old yttria' and to remember that such is the substance to which everything written concerning yttria prior to 1885 will be found to refer. Fig. 13 shows the simple phosphorescence spectra of the several components into which yttria may be split up by fractionation. If these components are taken in the order of their apparent basicity—the chemical analogue of refrangibility—the lowest of these constituents gives the deep-blue band G_a, then follows a strong citron band, G _{δ} , which increases in sharpness as it becomes more separated from its associates until it may be called a line, then a red band, G _{ϵ} , then a crimson band, G _{γ} , and, lastly, very close together a pair of greenish-blue bands, G _{β} .

The diagram, fig. 14, shows a series of nineteen phosphorescence spectra obtained from a prolonged examination of 'old yttria'. The central spectrum, J, is approximately that given by crude 'old yttria,' though this differs slightly according to the mineral from which the old yttria is extracted. After a time fractionation splits up the earth J into two earths here marked κ and λ , giving slightly different spectra. Fractionating κ gives π and ν , while λ on fractionation yields J and λ . It must not be thought that there is so great a difference between any two adjacent spectra as is here shown. To make the diagram accurately represent what is actually seen in the laboratory it would be necessary to place between each of these nineteen spectra about 1,000 intermediate spectra. Beginning at the extreme red it will be seen that a strong band at λ 647 [$1/\lambda^2$ 289] is at its maximum intensity from ϵ to κ , when it rapidly disappears and is not seen beyond ϵ and κ . The component giving this band the writer names provisionally G _{γ} . The next band in the red λ 689 [$1/\lambda^2$ 245] reaches its maximum at λ or even higher, and fades out be-

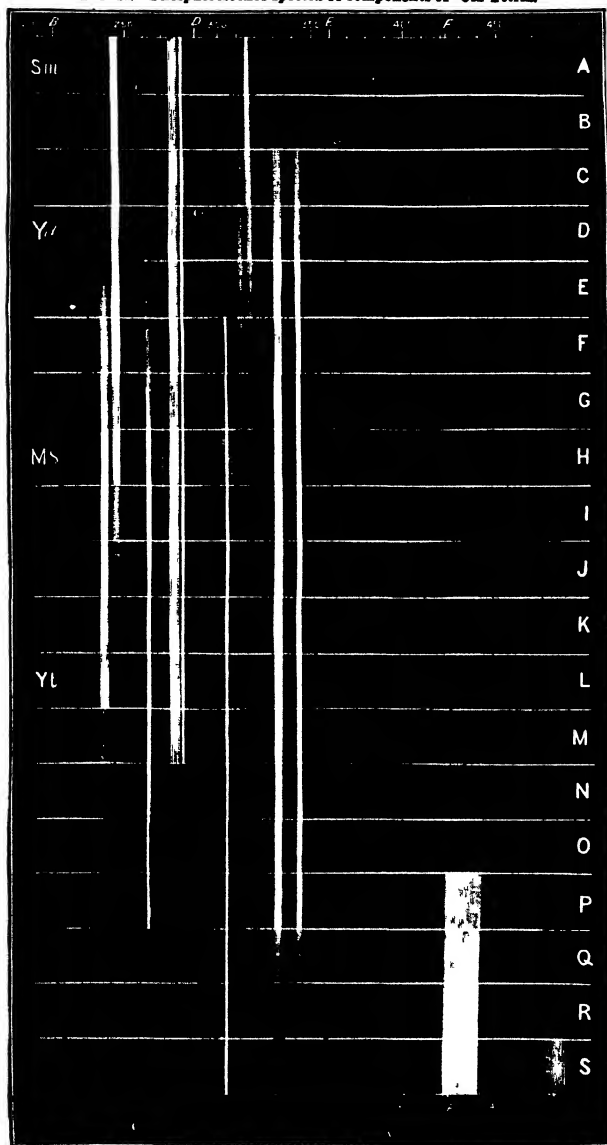

tween κ and λ . The band at λ 619 [$1/\lambda^2$ 261] has its maximum between κ and ϵ , dying out rapidly below but being more persistent above. It is called G _{ϵ} . Then comes an extremely sharp band λ 609 [$1/\lambda^2$ 269] which appears to belong to an earth absent in gadolinite but present in samarskite and a few other minerals. Its greatest brilliancy is between π and κ , and on either side it dies rapidly away. For this the writer proposes the name S _{δ} . Then follows a double orange band, and its two components, though very closely united, are probably capable of separation. The maximum brightness of the first component λ 603 [$1/\lambda^2$ 275] extends from ϵ to the top of the figure. The second component λ 597 [$1/\lambda^2$ 280] begins to fade about ϵ , and is at its greatest brilliancy at the highest spectrum shown on the figure. This band occurs almost isolated in a specimen of crude lanthana, and may be provisionally called G _{ϵ} . Next follows the citron, or G _{δ} band, λ 574 [$1/\lambda^2$ 305.5] which is the most prominent feature in the spectrum of old yttrium. This band extends with scarcely diminished sharpness from ϵ to π , above ϵ it fades rapidly and disappears above ν . Then follows a double green band separable into two components. The first of these, λ 568 [$1/\lambda^2$ 310] is nearly absent in λ , reaches a maximum at ν , and disappears at κ . The second member of this green pair, λ 563 [$1/\lambda^2$ 315] has its maximum at λ and extends only to π . The substance producing this pair of bands may be called for the present G _{γ} . Then follows a pair of bright green bands which so far show no signs of dividing. They begin at π , reach a maximum at ϵ , and continue with scarcely diminished brightness to ϵ . The body giving this double green band is remarkably persistent and may provisionally be called G _{β} . Next comes a dark interval followed by a broad, hazy, double blue band, with its centre at λ 482 [$1/\lambda^2$ 430.5], this band appears at ν and grows brighter to the last fraction at π . The substance to which it is due is called G_a. Lastly, at λ 456 [$1/\lambda^2$ 481] appears a deep violet band beginning at about ϵ and brightening as we proceed lower down. In some samples of ytterbia, supposed to be pure, this band is intensely brilliant, but it is absent in a specimen received from Nilson and considered by him to be perfectly pure. Hence it is probably due to another new body which may be provisionally named S _{γ} .

It must be remarked that the writer's fractionations have been carried far beyond the limits shown in the diagram. Fractions above λ and below π afford evidence that the process of differentiation has not yet reached its utmost limit.

On the left side of the diagram will be seen chemical symbols attached to some of the spectra. Thus the top spectrum, λ , is the one shown by samarium. At ν is the spectrum of Magnac's Y_a, or gadolinium. π shows the spectrum of mosandrum, and κ that which is generally pronounced to be pure yttrium. A careful study of this diagram will lead the observer to conclude that samarium, gadolinium, mosandrum, and yttrium are not true chemical elements but compounds, or perhaps very intimate mixtures, of certain simpler bodies. For these bodies the name 'meta-elements' is proposed (W. Crookes,

B A Birmingham Meeting, *C. N.* 54, 155, | be a complex body, and recognises in it three
 Krüss & Nilson, *B.* 20, 2134 and *C. N.* 54, 71, 85, | distinct substances which he names $Z\alpha$, $Z\beta$, and
 135, 142, 164, 165, 172, Marignac, *Archives des* | 'new yttria' (*C. R.* 103, 627) It is possible

The scale is $\frac{1}{\lambda}$

Sciences Physiques, 16, No 5 and *C. N.* 57, W. | that $Z\alpha$ is $G\beta$, and that $G\beta$ and $Z\beta$ are identical,
 Crookes, *Pr.* Feb 10, 1887) | though de Boisbaudran now regards the latter
 De Boisbaudran likewise finds yttrium to | body as terbium (*C. R.* 102, 395, 902)

The right of the 'new yttria' to bear this name is in the highest degree questionable. De Boisbaudran assigns to it an atomic weight close upon 89, and states that it has a characteristic spark-spectrum but gives no phosphorescence spectrum either in the radiant matter tube or by his reversion-process. It evidently cannot be regarded as the old yttrium freed from impurities, since the purest specimens of such yttrium give a phosphorescence spectrum *in vacuo* of such remarkable intensity that it cannot be due to mere traces of impurities. Ga, Gβ, &c., can no more be spoken of as impurities in old yttrium than can neodymium and praseodymium (assuming them to be elementary) be viewed as impurities in old didymium.

Marignac's Y_a is probably a compound. The writer recognises in it two at least of the constituents of yttrium, Gβ and Gγ.

A. E. Nordenskjöld gives the name oxide of gadolmium (a totally different body from Marignac's Y_a or gadolinium) to the mixture of earths in gadolinite which are precipitated by ammonia and oxalic acid, but not by sulphate of potash. This mixture consists of yttria, erbia, and ytterbia. A very interesting point is that however different the minerals from which it has been obtained, and however the percentage of the rare earths varies, the equivalent weight of the mixture is always approximately the same, viz 261.9. This value is determined by transforming a weighed quantity of the oxide into sulphate by digestion with dilute sulphuric acid, and driving off excess of water and acid by heating to incipient redness (Nordenskjöld, *C. R.* 102, 795, W. Crookes, *C. N.* 54, 239).

On the other hand, commenting on this, De Marignac shows that there is sometimes a variation of 15 p.c. in the equivalent weights of these natural mixtures of rare earths (De Marignac, *Arch. des Sci. Phys.* 17, No 5).

We have therefore some thirty bodies of which the so called rare metals are composed, or, at least, which they contain, and a variety of facts points to the conclusion that we have by no means come to the end. Several even of the new bodies give signs of a capability of further splitting up, if they are examined with sufficient nicety and persistence. It is far from unlikely that when the various methods of research known as fractionation have been more generally applied we may have to deal, not with thirty, but with nearer sixty, unknown bodies.

But whatever may be the number of these bodies the question must be raised, What are they? Are they each and all independent elements? We have certainly no good *a priori* grounds for asserting that the number of elements now recognised is not capable of considerable extension. But before any body can be accepted as simple it should certainly undergo a very severe scrutiny, more severe than of these newly-discovered bodies has yet undergone. The case of didymium is here a warning. It had been closely examined by some of the ablest chemists in Europe, it had been freed from several foreign bodies, its atomic weight had been established, when a novel mode of examination proved its compound nature.

Pending therefore the completion of a series of investigations, chemical and optical, which

will probably occupy several generations of chemists, it may be safest to call these recently observed bodies not, as yet, elements, but quasi or meta elements. Our notions of a chemical element have been enlarged, hitherto the elemental molecule has been regarded as an aggregate of two or more atoms, and no account has been taken of the manner in which these atoms have been agglomerated. The structure of a chemical element is certainly more complicated than has hitherto been supposed. We may reasonably suspect that between the molecules which we are accustomed to deal with in chemical reactions, and the component or ultimate atoms, there may intervene sub molecules, sub aggregates of atoms, or meta elements, differing from each other according to the positions which they occupy in the very complex structures commonly known as didymium, yttrium, and the like. W. C.

METAMERISM This term is generally applied to those cases of *isomerism* wherein compounds show identity of elementary composition, but belong to different types or classes (*v.* *ISOMERISM*, pp. 79, 80, 81, 88).

METEORITES As regards composition, meteorites have been divided into two classes, those which consist for the most part of metals only, and those which are chiefly composed of silicates, sometimes accompanied by unoxidised iron and nickel. Iron and nickel are the principal constituents of those meteorites which are mainly metallic. The quantity of Fe varies from 80 to 95 p.c., and of Ni from 6 to 10 p.c. Co occurs in many meteorites, varying from a mere trace to 2 or 3 p.c., the other metals found in small quantities are Sn, Mn, Cr, and Cu, small quantities of Fe-Ni phosphide, and also carbide, phosphide, silicide, and sulphide of Fe are also frequently found in metallic meteorites. The silicates which form the chief constituents of meteorites of the second class are silicate of Al, Ca, and Na (*labradorite*), silicate of Ca and Mg (*augite*), and silicate of Fe and Mg (*olivine*). These silicates are often accompanied by nickel and iron, also by iron pyrites, and sometimes by chrome iron, and magnetic oxide of iron. M. M. P. M.

METHACRYLIC ACID C₄H₆O₂, *ε*
OH, CMe CO₂H *a Methyl acrylic acid* [16°].
(160.5° i. v.) S.G. ²⁰ 1.0153 (Bruhl, *B.* 14, 2800) $\mu_D = 1.4314$ $n_D^{20} = 35.07$

Occurrence—In small quantity in Roman oil of chamomile (Kopp, *A.* 195, 89).

Formation—1 Obtained as ethyl ether by the action of PCl₅ on oxy-isobutyric ('dimethoxalic') ether CMe₂(OH)CO₂Et (Frankland & Duppa, *C. J.* 18, 133, *A.* 136, 12, Paul, *A.* 188, 52)—2 By the action of fuming HBr on citraconic acid, mesaconic acid, or citraconic anhydride, the resulting bromo-pyrotartaric acid being boiled with conc. NaOH aq. (Fittig, *A.* 188, 95, *B.* 10, 517)—3 By boiling citra and meso-chloro-pyrotartaric acid with alkalis (Pehrn, *A.* 188, 42)—4 Together with oxy-isobutyric acid, by boiling a bromo-isobutyric acid (1 pt) with water (25 pts) (Thomson, *A.* 200, 86).

Preparation—Citraconic anhydride is mixed with a saturated solution of HBr (2 vols.) at 0°. In a few days a mass of crystals of citra-bromo-pyrotartaric acid is got. These are collected,

boiled with Na_2CO_3 , acidified with HCl , and distilled. The distillate is neutralised by CaCO_3 , filtered, evaporated to dryness, and mixed with HCl . Methacrylic acid separates as a light oil (Fittig & C Kolbe, *J pr* [2] 25, 372).

Properties—Long prisms (from water), with strong but not unpleasant odour. V sol water, v a sol alcohol and ether.

Reactions—1 *Bromine* forms di-bromo isobutyric acid—2 *Potash fusion* gives hydrogen, formic acid, and propionic acid (F & D)—3 *Sodium-amalgam* reduces it to isobutyric acid—4 Conc HClAq forms, in the cold, iodoisobutyric acid crystallising in tufts of prisms—5 Methacrylic acid dissolves easily in fuming HBr even at 0° , the solution, after some time, depositing a crystalline addition product and a thick oil (Paul, *B* 9, 122)—6 *Bromine* forms CH_3Br $\text{CBrMe CO}_2\text{H}$ —7 On contact with cold conc HClAq or by heating at 130° , it is converted into an amorphous (? polymeric) modification. The ammoniacal solution of this substance gives white pps with Ba and Ca salts. It is not altered by conc H_2SO_4 and HNO_3 (Fittig & Engelhorn, *A* 200, 70)—8 *Hypochlorous acid* forms chloro oxy isobutyric acid [107°] (α 235°) (Mehlkoff, *Bl* [2] 41, 311).

Salts— CaA' , tufts of long needles, v sol water. Appears to change on keeping to a salt of the polymeric acid (v Reaction 7)— AgA' needles (from boiling water), scarcely affected by light. Suddenly decomposes at 100° .

Constitution—Inasmuch as the di-bromo isobutyric acid, formed by the addition of bromine, is converted by boiling water into a bromo oxy butyric acid that can be reduced to a oxy isobutyric acid, $(\text{CH}_3)_2\text{C}(\text{OH})\text{CO}_2\text{H}$, it is clear that methacrylic acid is not $\text{CH}_3\text{CHMe CO}_2\text{H}$ but $\text{CH}_3\text{CMe CO}_2\text{H}$.

Occurrence—The bubbles of gas given off by decaying vegetable matter in stagnant pools consist of marsh gas, CO_2 , and nitrogen. It often escapes into coal mines, where it is known as fire damp, since it forms an explosive mixture with air. It escapes from the earth in various places, as in Italy, North America, and especially at Baku on the Caspian. It occurs among the products of distillation of wood, peat, coal, and bituminous shale, constituting 35 to 40 p c of coal gas. Methane occurs also in the intestinal gases. It occurs also among the products of the passage of ethylene (Norton & Noyes, *Am* 8,

862) and other gases through a red hot tube. The gaseous product obtained by heating ethylene at 400° contains 36 p c methane and 40 p c ethane (Day, *Am* 8, 153).

Formation—1 By the action of potassium-amalgam on COI , in presence of water (Regnault). 2 By passing a mixture of CHCl_3 or COI , and hydrogen through a red-hot tube (Berthelot)—3 By the action of powdered zinc on chloroform dissolved in aqueous alcohol (Sabanejeff, *B* 9, 1810)—4 By exposing a mixture of CO and hydrogen to the action of electricity in an induction tube (Brodie, *Pr* 21, 245)—5 By the action of water on zinc methide (Frankland)—6 By the action of sodium on MeI in presence of ether (Wanklyn & Buckeisen)—7 In small quantity by passing a mixture of CS_2 and H_2S over red hot copper (Berthelot, *A Ch* [3] 53, 69) 8 By heating CS_2 with PH_3I at 130° (Jahn, *B* 13, 127)—9 Among the products of the dry distillation of barium formate (Berthelot, *J* 1857, 426)—10 By distilling crystallised sodium acetate (2 pts) with KOH (2 pts) and quicklime (3 pts) (Dumas, *A Ch* [2] 73, 92) Von Schlegel (*A* 226, 140) recommends 1 pt of sodium acetate and 2 pts of soda lime (*cf* Schorlemmer, *C N* 29, 7)—11 When river mud is added to a solution of calcium acetate a slow evolution of a mixture of methane (2 vols) and CO_2 (1 vol) occurs, calcium carbonate being left. Calcium lactate undergoes a similar fermentation, the gases being evolved in the same proportion (Hoppe Seyler, *H* 11, 561).

Preparation—By the action of the copper-zinc couple on an alcoholic solution of MeI , the escaping gas being well washed by a scrubber containing a further quantity of copper zinc (Gladstone & Tribe, *C J* 45, 154).

Properties—Colourless gas. V sl sol. water. Much less soluble in alcohol than ethane. Its illuminating power is slight (*cf* L T Wright, *C J* 47, 200). May be liquefied by combined cold and pressure (Cailletet, *J* 1877, 221). Methane is not absorbed by aqueous KOH or by ammoniacal cuprous chloride. When compressed with water below 0° under a pressure of 30 atmospheres it forms a crystalline hydrate, the critical temperature of which is 21.5° (Villard, *C R* 106, 1602, 107, 395).

Reactions—1 When passed through a red-hot tube it is for the most part unaffected, but a little naphthalene is formed. *Electric sparks* partially convert it into carbon, hydrogen, and acetylene (Berthelot, *C R* 67, 1188). When passed over a red hot palladium spiral it is decomposed, if dry, into carbon and hydrogen, and, if moist, into CO and hydrogen (Coquillon, *C R* 86, 1197)—2 It is not attacked by sulphuric acid, by nitric acid, by a mixture of hot conc H_2SO_4 and HNO_3 , by POI , or by chlorine in the dark—3 A mixture of chlorine (2 vols) with methane (1 vol) when exposed to sunlight presently explodes. The explosion may also be brought about by an electric spark. If the mixture be first diluted with CO , and then exposed to sunlight, quiet chlorination takes place, and if excess of chlorine is present chloroform and CCl_4 are formed. A mixture of methane (1 vol) and chlorine (1 vol) exposed to diffused daylight gives methyl chloride. In presence of moisture, chlorine forms HCl , CO_2 , and CO .—

4 A mixture of air and methane passed over a red-hot platinum spiral yields formic acid (Coquillon, *C R* 77, 444)—5 When mixed with nitric oxide and fired by an electric spark CO, and oxygen are among the products (Cooke, *C N* 58, 130)

Constitution—That the four atoms of hydrogen in methane are of equal value may be inferred from the existence of only one set of methyl compounds The same thing may be shown thus—

From CHHHI we may obtain, by treatment with KCy, an acetonitrile CHHHCy which we may call 'α' From this we can obtain CHHH CO₂H, CHHCl CO₂H, CHHCy CO₂H, and 'β' acetonitrile CHHCyH successively But from CHHCy CO₂H we can obtain malonic ether CHH(CO₂Et)(CO₂Et), and thence we can get CHCl(CO₂Et)(CO₂Et), CHCy(CO₂H)(CO₂H), and 'γ' acetonitrile CHCyHH successively The three acetonitriles 'α', 'β', and 'γ' are then found to be identical, hence three at least of the atoms of hydrogen in methane are of equal value The fourth acetonitrile might probably be obtained from CH(CO₂Et), *via* CCl(CO₂Et)₃, and CCy(CO₂H)₃ (Henry, *C R* 104, 1106) Since

$\text{CO} \begin{smallmatrix} \text{Cl} \\ \text{OEt} \end{smallmatrix}$ the product of the action of CO $\begin{smallmatrix} \text{Cl} \\ \text{OEt} \end{smallmatrix}$ on isobutyl alcohol, is the same as CO $\begin{smallmatrix} \text{OEt} \\ \text{OC}_2\text{H}_5 \end{smallmatrix}$, obtained from CO $\begin{smallmatrix} \text{Cl} \\ \text{OC}_2\text{H}_5 \end{smallmatrix}$ and ethyl alcohol, the carbonyl group is united to two atoms of hydrogen of equal value Now from aldehyde CO $\begin{smallmatrix} \text{H} \\ \text{CH}_3 \end{smallmatrix}$ we may obtain

$\text{Cl} \begin{smallmatrix} \text{O} \\ \text{AcO} \end{smallmatrix} \text{C} \begin{smallmatrix} \text{H} \\ \text{CH}_3 \end{smallmatrix}$ whence silver propionate forms $\text{C}_2\text{H}_5\text{O} \begin{smallmatrix} \text{O} \\ \text{AcO} \end{smallmatrix} \text{C} \begin{smallmatrix} \text{H} \\ \text{CH}_3 \end{smallmatrix}$ But from aldehyde we

may also obtain $\text{Cl} \begin{smallmatrix} \text{O} \\ \text{C}_2\text{H}_5\text{O} \end{smallmatrix} \text{C} \begin{smallmatrix} \text{H} \\ \text{CH}_3 \end{smallmatrix}$ whence silver acetate yields $\text{AcO} \begin{smallmatrix} \text{O} \\ \text{C}_2\text{H}_5\text{O} \end{smallmatrix} \text{C} \begin{smallmatrix} \text{H} \\ \text{CH}_3 \end{smallmatrix}$

These two acetyl propionyl derivatives of ortho aldehyde are found to be identical, hence the two atoms of hydrogen in methane which are displaced by oxygen in forming carbonyl are of equal value It follows that there are two pairs of equivalent atoms of hydrogen in methane (Geuther, *A* 205, 203, 225, 290) And since Henry has shown that three of the atoms of hydrogen in methane are equivalent, it follows that the fourth is so also

References—TETRA BROMO, BROMO IODO, BROMO-NITRO, CHLORO IODO, CHLORO-NITRO, and TETRA IODO, METHANE, BROMOFORM, CHLOROFORM, IODOFORM, and METHYL, METHYLENE, and METHENYL COMPOUNDS In fact, all organic compounds may be regarded as derivatives of Methane (Kekulé)

METHANE CARBOXYLIC ACID IS ACETIC ACID

Methane dicarboxylic acid IS MALONIC ACID
Methane tricarboxylic acid C₂H₃O₆ *ie* CH(CO₂H)₃ Formyl tricarboxylic acid
Methenyl tricarboxylic acid

Ethyl ether CH(CO₂Et), [29°] (258°) at 760 mm (195°–205°) at 140 mm S G $\frac{1}{2}$ 1.100 From sodium malonic ether, benzene and ClCO₂Et (Conrad & Guthzeit, *A* 214, 81; B.

12, 1286, cf Claisen, *B* 21, 8897, 3567) Colourless oil V sol alcohol ether In a freezing mixture, it solidifies to long needles or prisms According to Michael (*J pr* [2] 87, 473) it dissolves readily in dilute NaOH forming ONa(CO₂Et)₃, which may be crystallised

Reactions—1 With aqueous KOH at 100° it forms HOEt, K₂CO₃ and potassium malonate—2 Dilute H₂SO₄ and alcoholic NaOH at 0° also form malonic acid; so that a salt of the acid CH(CO₂H)₃ has not been obtained—3 Chlorine forms CCl(CO₂Et)₃ (Conrad *B* 14, 618)

Anilide of the di-ethyl ether
CH(CO₂Et)₂(CONHPh) [124°] From sodium-malonic ether and an alcoholic solution of phenyl cyanate (Michael, *J pr* [2] 35, 452)

Nitrile of the di-ethyl ether v CYANO MALONIC ETHER

METHANE PHOSPHONIC ACID v METHYL PHOSPHINE

METHANE - TRI - QUINOLYL - HYDRO - IODIDE v QUINOLINE IODOFORM

METHANE SELINIC ACID v SELENIUM ORGANIC COMPOUNDS

METHANE SULPHINIC ACID CH₃SO₂ *ie* CH₃SO₂H From ZnMe₂ and SO₂ (Hobson, *A* 106, 287) The aqueous solution of the acid soon decomposes with deposition of sulphur—CaA', (dried at 100°) amorphous—BaA', (dried at 100°) cubes, v sol water, insol alcohol—MgA', aq (dried at 100°)—ZnA', amorphous

Derivative—TRI CHLORO METHANE SULPHINIC ACID

Methane di-sulphinic ether v METHYLENE DIPHENYL DISULPHONE

METHANE SULPHONIC ACID CH₃SO₃ *ie* CH₃SO₃H

Formation—1 By the oxidation of di methyl trisulphide (Cahours, *A Ch* [3] 18, 258), or of dimethyl disulphide (Muspratt, *A* 65, 251)—2 By oxidising methyl sulphocyanide with nitric acid (S G 1 25)—3 By treating tri chloro methane sulphonic acid with sodium amalgam (Kolbe, *A* 54, 174)—4 By heating MeI with aqueous K₂SO₄ at 120° (Colman, *A* 148, 101)

Properties—Syrup which decomposes above 130° Potash fusion forms K₂CO₃, hydrogen, and K₂SO₄ (Berthelot, *J* 1869, 336)

Salts—NH₄A' thin trimetric plates (from absolute alcohol)—LiA' aq—(NaA'), NaI (Colman)—KA' (dried at 100°)—KHA', (dried at 100°)—CaA', S 71 at 20° (Nithaok, *A* 218, 284)—SrA' aq S 83 at 22°—BaA' aq v e sol water, insol alcohol—MgA', 10 aq—FbA' aq—CuA', 5 aq—AgA'

Chloride CH₃SO₂Cl (160°) (N) S G 1.51 From the acid and PCl₅ (Carius, *A* 114, 142) Not attacked by H₂S, by chlorine, or by KCy (McGowan, *J pr* [2] 80, 280) Decomposes aqueous ammonia with evolution of nitrogen

Amide CH₃SO₂NH₂ Formed by passing NH₃ into a solution of the chloride in ether. Prisms (from benzene containing alcohol)

Anilide CH₃SO₂NHPh Large plates (from alcohol) (McGowan)

Derivatives v CHLORO-, and CHLORO-BROMO-METHANE SULPHONIC ACID

Methane disulphinic acid CH₃S₂O₂ *ie*. CH₃(SO₂H)₂ Methylene disulphonic acid. Methionic acid

Formation.—1. A product of the action of

SO₂ on ether (Liebig, *A* 13, 35, Wetherill, *A* 66, 122, Strecker, *A* 100, 199) — 2 From Et₂SO₂ and SO₂ (Hubner, *A* 223, 208) — 3 By the action of hot fuming H₂SO₄ on acetonitrile, acetamide, or sulpho-acetic acid (Buckton & Hofmann, *A* 100, 133, *C J* 9, 241) — 4 Together with sulpho-acetic acid, by the action of ClSO₃H on acetic acid (Baumstark, *A* 140, 82) — 5 By heating lactic acid with fuming H₂SO₄ (Strecker, *A* 118, 290) — 6. From methylene iodide and K₂SO₄ (Strecker, *A* 148, 90) — 7 By heating chloroform with aqueous K₂SO₄ at 180° (Strecker) — 8 From CCl₄, SO₂, K₂SO₄, water, and K₂SO₄ at 125° (Rathke, *A* 161, 152) — 9 By oxidising CH₃(SCy)₂ with HNO₃ (Lermontoff, *B* 7, 1282)

Properties — Very deliquescent needles Not attacked by chlorine or by nitric acid

Salts — (NH₄)₂A'' trimetric crystals, m. sol cold water — K₂A'' needles *S* 7.1 at 22° — BaA'' 2aq pearly tables — PbA'' 2aq prisms, v sol water, insol alcohol — CuA'' 5aq — Ag₂A'' thin plates

Derivative v BROMO METHANE DISULPHONIC ACID

Methane tri-sulphonic acid CH₃S₃O₆ v.e CH(SO₃H)₃ Obtained by heating CH₃O SO₃K (1 pt) with fuming H₂SO₄ at 100° (Theilkuhl, *A* 147, 134) Formed also by the action of aqueous K₂SO₄ at 100° on CH₃C(NO₂)(SO₃K)₂ or on CCl₃(NO₂) (Rathke, *A* 167, 219) Long needles, v.e sol water and alcohol — K₂A''' 2aq small prisms — Ca₂A''' 12aq small prisms, v sol water, insol alcohol — Ba₂A''' 9aq plates Not decomposed by HCl — Pb₂A''' 2aq

METHANE THIOSULPHONIC ACID

Methyl ether C₂H₅SO₂ v.e CH₃SO₂ SCH₃ *Dimethyl disulphoxide* Obtained by warming dimethyl disulphide with nitric acid (*S G* 12) diluted with four times its volume of water (Lukashevitch, *Z* 1868, 641) Oil Readily oxidised by HNO₃ to methane sulphonic acid

METHANTHRENE C₁₃H₁₂ [117°] An isomeride of methyl naphthalene obtained, together with other products, by distilling podocarpic acid with zinc dust (Oudemans, *B* 6, 1125) The product is crystallised from alcohol and sublimed White laminae with violet fluorescence It boils above 360° V.e sol. boiling alcohol, CS₂, and HOAc

Picric acid compound

C₁₃H₇C₆H₃(NO₂)₃OH [117°] Slender orange needles

Methanthrene-quinone C₁₃H₆O₂ [187°] From methanthrene and CrO₃ in HOAc Minute trimetric laminae May be distilled Insol water, sl sol ether, v sol alcohol Reduced to a hydride by aqueous SO₂

METHAZONIC ACID C₁₃H₈N₂O₄ v.e.

NO (CH₃)₂O? [*c* 60°] The sodium salt is formed by acting on nitro methane with alcoholic NaOH, the resulting crystalline pulp being heated on the water bath The upper (alcoholic) layer is poured off, and the lower layer deposits sodium methazonate on cooling It is dissolved in water and reprecipitated by alcohol (Friese, *B* 9, 304) According to Lecco (*B* 9, 706) it is best to add dilute H₂SO₄ and shake with ether If the ether is dried with Na₂SO₄ and evaporated over H₂SO₄, it leaves methazonic acid as large crystals, which may be recrystallised from benzene. It is v. sol

water, alcohol, and ether, m sol benzene, insol petroleum naphtha The Na salt crystallises from alcohol in long prisms

METHENYL-AMIDINE v FORMAMIDINE

METHENYL-AMIDOXIM v FORMAMIDOXIM

METHENYL-AMIDO-*o*-CRESOL C₇H₇NO v.e.

C₆H₄(OH)₂<N>CH [*s* 1 1/2] [39°] (200°) Colourless crystals Prepared by the action of formic acid on amido-*o* cresol (Hofmann & Miller, *B* 14, 570)

Methenyl-amido *p*-cresol C₇H₇NO v.e.

C₆H₄(CH₃)<N>CH [*s* 5 1/2] [46°] Formed from amido *p* cresol by distillation with formic acid (H & M) Crystals

METHENYL (α) AMIDO NAPHTHYL MER-

CAPTAN C₁₀H₇<N>CH [46°] Formed by heating formyl (α) naphthylamine with sulphur Colourless oily fluid Insol water Volatile with steam Base — B₂H₂Cl₂PtCl₄ yellow needles (Hofmann, *B* 20, 1799, 2265)

METHENYL-AMIDO-PHENOL C₇H₇NO v.e.

C₆H₄<N>CH [30 5°] (182 5°) V D (H—1) 112.5 (calc 119) Obtained by boiling formic acid with *o* amido phenol (Ladenburg, *B* 10, 1123) Prisms Hot conc HCl aq decomposes it, forming *o* amido phenol

METHENYL-AMIDO-PHENYL MERCAP-

TAN C₇H₇NS v.e [12] C₆H₄<S>CH (230°) Colourless fluid Sparingly soluble in water, easily in alcohol and CS₂. Has decided basic properties Heavier than water Volatile with steam Isomeric with phenyl mustard oil

Preparation — 1 By reduction of the chloro derivative (vol u p 78) with tin and HCl or with HI — 2 By the action of formic acid on amido phenyl mercaptan (Hofmann, *B* 13, 14) — 3 Formed together with aniline, methyl aniline, and a base C₆H₅NS₂ by boiling dimethyl aniline with sulphur (Mohlau & Krohn, *B* 21, 59)

Properties — Oil, smelling like quinoline and having a bitter taste It is related to thiazole as quinoline is to pyridine The sulphur cannot be displaced by the action of lead hydrate or even by heating with copper to 250° On fusion with KOH it gives formic acid and amido phenylmercaptan PCl₅ at 180° forms the chloro derivative C₆H₄(NS)CCl

Salts — (B'HCl).PtCl₄, sparingly soluble tables, or needles — (B'HCl)AuCl₃ — B₂H₂FeCy₄ *Methylo-iodide* C₇H₇NSMeI [210°]; needles, sl sol cold alcohol, v sol hot water

General character — This base stands in the same relation to quinoline as thiophene stands to benzene In consequence of this analogy the base and its derivatives exhibit great similarity in properties with the corresponding quinoline compounds thus the boiling-points of the methenyl- and ethenyl-*o* amido phenyl mercaptan do not differ much from those of quinoline and methyl-quinoline, and they form crystalline picrates and uncrystallisable chromates They also form colouring-matters analogous to the cyanines (obtained by the action of alkalis upon a mixture of the alkyl-iodides of quinoline and methyl quinoline) Thus by boiling an aqueous solution of the amyl-iodides of methenyl- and

ethenyl amido-phenyl mercaptans with NH_3 , a red colouring matter $\text{C}_6\text{H}_4\text{N}_2\text{S}_2\text{I}$ is obtained which crystallises in four sided violet red plates with green reflex, sol hot alcohol, sl sol cold alcohol, insol water. Neither of the amylo iodides when treated separately, in the same way, gives any colouring matter. In a similar manner to the amylo iodides, the mixed methyl iodides give a compound crystallising in reddish-golden plates, sol alcohol with a scarlet red colour. Similar colouring matters are also obtained from the corresponding derivatives of amido naphthyl mercaptan, or from the latter derivatives conjointly with those of amido phenyl mercaptan, or from those of amido phenyl-mercaptan conjointly with those of quinoline and methyl-quinoline. All the above products are stronger colouring matters than the cyanines (Hofmann, *B* 20, 2262).

Derivatives v AMIDO-, CHLORO-, and NITRO-METHENYL-AMIDO PHENYL-MERCAPTAN

METHENYL-*o*-AMIDO-PHENYL-MERCAPTAN α -CARBOXYLIC ACID $\text{C}_6\text{H}_4\langle\text{N}\rangle\text{C}\text{CO}_2\text{H}$ [108°]

Formation—1 By the action of cold alcoholic caustic potash upon amido imido ethenyl-*o*-amido phenyl mercaptan

$\text{C}_6\text{H}_4\langle\text{N}\rangle\text{C}\text{C}(\text{NH}_2)\text{NH}$, ammonia being eliminated—2 In small quantity by oxidation of ethenyl-*o*-amido phenyl mercaptan

$\text{C}_6\text{H}_4\langle\text{N}\rangle\text{C}\text{CH}_3$ with cold aqueous KMnO_4

Properties—White needles. Sol water and alcohol. It very readily splits off CO_2 giving methenyl amido-phenyl mercaptan (Hofmann, *B* 20, 2256)

METHENYL AMIDO-TOLYL MERCAPTAN

$\text{C}_6\text{H}_4(\text{CH}_3)\langle\text{N}\rangle\text{CH}$ [1 4] [15°] (255°) Prepared by boiling *p*-amido *m*-tolyl-mercaptan with formic acid (Hess, *B* 14, 492). Sol alcohol and ether. Weak base forming unstable salts— $\text{B}'\text{HCl}$, PtCl_4 , needles

METHENYL AMIDOXIM v FORMAMIDOXIM

METHENYL-AMIDO XYLIL MERCAPTAN

$\text{C}_6\text{H}_4(\text{CH}_3)\langle\text{N}\rangle\text{CH}$ From the thio-formyl derivative of *u m* xylylidine $\text{C}_6\text{H}_4\text{Me}_2(\text{NHCSH})$ by oxidising with alkaline K_2FeC_6 (Gudeman, *B* 21, 2549). Heavy oil

METHENYL-BROMO-TOLYLENE-*o*-DI-

AMINE [1 4 2] $\text{C}_6\text{H}_4(\text{CH}_3)(\text{Br})\langle\text{N}\rangle\text{CH}$ [187°]. Obtained by heating bromo-tolylene-diamine with formic acid (Hubner & Schupphaus, *B* 17, 776). Fine colourless needles. Sol alcohol, ether, and acetone, sl sol water and benzene

Salts— $\text{B}'\text{HCl}$ colourless soluble needles— $\text{B}'\text{H}_2\text{SO}_4$ long needles— $\text{B}'\text{HNO}_3$ sparingly soluble colourless needles— $\text{B}'\text{H}_2\text{Cl}_2\text{HgCl}_2$ needles— $\text{B}'\text{H}_2\text{Cl}_2\text{PtCl}_4$ orange crystalline pp— $\text{B}'\text{H}_2\text{CrO}_4$ glistening red needles— $\text{B}'\text{C}_2\text{H}_5(\text{NO}_2)_2\text{OH}$ this picrate forms yellow needles [229°]

METHENYL-TRICARBOXYLIC ACID v.

METHAN-TRICARBOXYLIC ACID

METHENYL FLUORIDE CHF_3 . *Fluoroform*. *V.D.* 250 (sale 244) δ (alcohol) 6

Formed by warming a mixture of iodoform (2 pts), chloroform (1 pt), and silver fluoride (2 pts) (Meslans, *C.R.* 110, 717). Colourless gas, condensing at 20° under 40 atmospheres' pressure. Smells like chloroform, and burns with blue flame forming HF . Sl sol water, chloroform, and benzene. Alcoholic KOH yields KF and potassium formate

METHENYL DI-PHENYL-DIAMINE v. DI-PHENYL FORMAMIDINE

METHENYL-*o*-PHENYLENE-DIAMINE

$\text{C}_6\text{H}_4\langle\text{NH}\rangle\text{CH}$ *Anhydro-formyl phenylene diamine* [167°] (above 360°). Prepared by heating *ortho* phenylene diamine for 5 or 6 hrs with formic acid. The yield is nearly theoretical (Wundt, *B* 11, 826). Large crystals. Monacidic base— $\text{B}'\text{HCl}$, PtCl_4 — $\text{B}'\text{HCl}$ AuCl_3

METHENYL TRI-PHENYL TRIKETONE

v TRI-BENZOYL METHANE

METHENYL DI-TOLYL-AMIDINE v. DI-TOLYL FORMAMIDINE

METHENYL-TOLYLENE-*o* DIAMINE

$\text{C}_6\text{H}_4(\text{CH}_3)\langle\text{NH}\rangle\text{CH}$ [1 2 3] [143°]. Obtained by reduction of methenyl bromo tolylene-*o* diamine (Hubner & Schupphaus, *B* 17, 777). Colourless glistening needles (from benzene). V e sol water and alcohol

Salts— $\text{B}'\text{HNO}_3$ long soluble needles— $\text{B}'\text{H}_2\text{Cl}_2\text{PtCl}_4$ 3aq sparingly soluble orange needles

Methenyl-tolylene-diamine

$\text{C}_6\text{H}_4(\text{CH}_3)\langle\text{NH}\rangle\text{CH}$ [1 3 4] [c 101°]. From the diamine and formic acid (Ladenburg, *B* 10, 1123)— $\text{B}'\text{H}_2\text{PtCl}_4$ yellow prisms

METHIONIC ACID v METHANE DISULPHONIC ACID

METHOXY-compounds v Methyl derivatives of Oxy. compounds

METHRONIC ACID $\text{C}_6\text{H}_4\text{O}$, *s.e.* $\text{C}_6\text{H}_4\text{O}(\text{CO}_2\text{H})_2$, $\text{C}(\text{CO}_2\text{H})_2\text{CH}$

or $\text{CMeO} \parallel \text{CCH}_2\text{CO}_2\text{H}$ (Knorr, *B* 22, 152)

Di methyl furfuranedicarboxylic acid *Sylvane carboxyacetic acid* *Pyrotritanic carboxylic acid* [205°] (F), [207°] (P)

Formation—1 By heating equimolecular weights of aceto acetic ether, Ac_2O , and sodium succinate, and saponifying the resulting mono ethyl methronate $\text{C}_6\text{H}_4\text{O}(\text{CO}_2\text{Et})(\text{CO}_2\text{H})$ with baryta (Fittig, *A* 250, 173, 182). 2 By treating a mixture of glyoxal and aceto acetic ether with a concentrated aqueous solution of ZnCl_2 , and extracting the product with aqueous KOH (Polonowsky, *A* 246, 6, Fittig & Hantzsch, *B* 21, 2135, 3189)

Properties—Needles (from water), v e sol. alcohol, m sol ether and HOAc , m sol hot, v. sl sol cold, water, almost insol CHCl_3 and CS_2 . The aqueous solution gives no colour with FeCl_3 . It is not attacked by reducing agents

Reactions—1 On heating it gives off carbonic acid gas leaving methyl-furfuryl acetic

$\text{OH} \parallel \text{CH} \parallel \text{CMeO} \parallel \text{CCH}_2\text{CO}_2\text{H}$ [188°]. — 2 Dilute

HCl aq at 200° gives CO_2 and acetyl acetone.

Salts— $(\text{NH}_4)'\text{A}'$ 3aq small needles— $\text{C}_2\text{H}_5\text{A}'$: heavy crystalline pp nearly insol.

hot water —CaA'' 2aq —BaA'' 2aq needles (P) —BaA'' amorphous (F) —BaH₂A'' needles, more soluble than the Ca salt (F) —Ag₂A'' aq bulky white pp

Mono-methyl ether MeHA'' [98°]; needles —AgMeA'' white pp (F)

Di methyl ether Me₂A'' Oil

Mono-ethyl ether EtHA'' [76°] Prepared as above Long pointed needles, v sol alcohol, ether, chloroform, and benzene, m sol CS₂, sl sol water —Ca(EtA'')₂ 2aq needles or prisms —Ba(EtA'')₂ 2aq needles, v sol hot, sl sol cold, water —AgEtA'' white matted needles

Di ethyl ether Et₂A'' (300°–305°) (F)

Phenyl hydrazide C₁₀H₁₁N₃O₂ 16 C₁₀H₉O₂N₂HCl₂ [212°] (F)

Phenyl hydrazide of the mono-ethyl ether C₁₀H₁₁N₃O₂ [134°], crystalline Insol cold aqueous alkalis

METHRONOL C₁₁H₂₀ 16

CH CH C CHPh CHMe
| CH CH O CH₂ CHMe ? *Phenyl di methyl*

naphthalene tetrahydride (323°) V D 80 (calc 82) Formed from phenyl methacrylic acid by heating with H₂SO₄ (40 cc) and water (60 cc) (H Erdmann, A 227, 250) Oil Chromic mixture oxidises it to o benzoyl benzoic acid, acetic acid, benzoic acid, anthraquinone, and CO₂

METHYL The radicle CH₃ The name methyl was also given by Frankland and Kolbe (C J 1, 60) to dimethyl C₂H₅, now called ethane The methyl derivatives of hydroxylic compounds are described under the compounds of which they are the ethers e.g. CH₃O C₂H₅, CO₂H₂, the methyl derivative of oxy benzoic acid is described under Oxy benzoic acid

C₆H₄ [114°]. Formed by heating

diphenylamine (50 g), glacial acetic acid (80 cc), and ZnCl₂ (85 g.) at 220° for 14 hours The yield is good (82 g) (Bernthsen, A 224, 85) Formed also by heating diphenylamine with acetone nitrile at 200° (Bernthsen, A 192, 29) Dimetric crystals, α = 1 2397 (Bernthsen a. Osann, B 19, 427) Aqueous KMnO₄ at 100° oxidises it very slowly, a product being perhaps quinoline tri carboxylic acid. HNO₃ (S G 138) boiled for 6 hours with methyl acridine (6 g) gives tri-nitro-acridine-carboxylic acid, which forms glittering

prisms, sparingly soluble in the usual menstrua —B'HCl.—B'H₂PtCl₆.

Methylo-iodide B'MeI [185°], red needles (from water). Sol hot water, less sol hot alcohol, least sol ether

Methylo-chloride B'MeCl. Decomposes at 180°–185°.

Methylo-hydroxide B'Me(OH) From the methylo iodide by treatment with aqueous NaOH Grey powder, turning green in air Sol. alcohol, but soon decomposes

[132°] Formed by distilling diamido-di-*p* tolyl-phenyl methane PhCH(OH)(C₆H₄MeN₂H₂) with zinc dust (Ullmann, *J pr* [2] 86, 265) Yellow matted needles Smells aromatic, and causes sneezing V sol water, v sol alcohol, ether, benzene, and hot petroleum ether Its solution in dilute H₂SO₄ exhibits bluish green fluorescence

Di-methyl-acridine C₁₈H₁₁N + e

by heating phenyl *p* toluidine (12 g) with HOAc (66 g) and ZnCl₂ (18 g) at 230° (Bonna, *A* 239, 64) Needles or prisms (from alcohol) Volatile with steam V sol alcohol and benzene —B'HCl yellow needles —B'HI orange red needles —B'C₆H₄(NO₂)₂OH brown crystals —The sulphate is reddish-brown

Methyl-acridine chloral v **TRI CHLORO OXY-PROPYL-ACRIDINE**

DI-METHYL-ACRYLIC ACID v **PENTENOIC ACID**

TETRA-METHYL ADIPIC ACID C₁₀H₁₈O₄ + e CO₂H CH₂·OMe₂·CMe₂·CH₂·CO₂H? [210°] A product of the action of finely-divided silver on α -bromo-isovaleric ether CHMe₂·CHBr CO₂Et (O Hell a W Mayer, *B* 22, 62) Snowy-white granules (from benzene), v sol alcohol and chloroform. Forms no anhydride on heating (difference from di-isopropyl succinic acid which accompanies it in its preparation) May be sublimed —BaA'' 5aq S 12.5 at 15° —MnA'' 3aq S 5.9 at 25° —NiA'' 4aq S (of NiA'') 4.7 at 25° —CoA'' 3aq. S (of CoA'') 6.65 at 23° —ZnA'' S 195 at 18° —CdA'' 3aq S 2.29 at 81° —CuA'' S 0.24 —PbA'' S 0.45 at 18° —AgA'' S 0.46 at 18°

METHYLALACREATINE v **ALACREATINE**

METHYL ALCOHOL CH₃O·e·OH, **OH Oxy-methane** *Methyl hydroxide* *Wood spirit* *Wood naphtha* Mol w 32 (84°8') (R Schuff, *A* 220, 99), (65°9') (Perkin, *O J* 45, 465), (66°2') (Zander) S G $\frac{7}{8}$ 7953 (Brühl), $\frac{11}{16}$ 79726, $\frac{11}{16}$ 78941 (Perkin), $\frac{11}{16}$ 8111 (Zander) S V 42.7 (5), 42.6 (Lossen, *A* 254, 55) μ_D = 1.3832 n_D = 1.293 (Brühl) H F p 51,450 (Thomsen), 61,400 (Stohmann, *J pr* [2] 40, 358) H.F.v. 50,560 (Thomsen, *Th*). H O 170,600 (Stohmann). M.M.1 640 at 18.7°. *Compressibility*. 00010879 at 15° (Dupré, *Pr* 20, 386)

Occurrence.—Free in the juices of plants (Guthzeit, *J*, 1879, 905, Maquenne, *O R* 101, 1067) and in the aqueous distillate in the fruits of *Horaceum* (Guthzeit, *A*, 177, 844; 240, 248).

Methyl alcohol occurs also in the product of the distillation of wood (Taylor [A.D. 1812], *Tilloch's Phil Mag* 60, 315, Dumas a Peligot, *A* 15, 1; *A Ch* 58, 5, 61, 193) and of colophony (Kalbe a. Lwow, *B* 16, 851) It occurs as methyl salicylate in oil of winter-green (*Gaultheria procumbens*)

Formation.—1 From methane by chlorinating, and heating the resulting methyl chloride with aqueous KOH for 7 days at 100° (Berthelot, *A* 105, 241) The MeCl may also be treated with HOAc and NaOAc at 200°, and the resulting MeOAc saponified MeCl treated with Ag₂SO₄ and H₂SO₄ at 100° gives HMeSO₄, whence methyl alcohol can be readily obtained —2 From hydrogen cyanide by reduction with zinc and H₂SO₄, and treating the resulting methylamine with nitrous acid (Linnemann, *Z* [2] 4, 284) —3 By distilling calcium formate (Lieben a. Paternò, *G* 3, 290, *A*, 167, 293, Friedel a. Silva, *O R* 76, 1545)

Preparation.—The crude watery liquid obtained by the distillation of wood contains methyl alcohol, acetone, acetic acid, methyl acetate, and ammonium acetate It is separated from the tarry products and redistilled, the first tenth of the distillate is mixed with slaked lime and redistilled, a little sulphuric acid is then added, and the liquid redistilled and rectified over quicklime The crude wood spirit thus obtained has a strong aromatic odour and turns brown on keeping. It contains methyl acetate, acetone, di-methyl acetic orthoaldehyde CH₃CH(OMe)₂ (Daneer, *C J* 17, 222), allyl alcohol, methyl ethyl ketone, and other ketones (Grodzky a. Krämer, *B*, 9, 1920) Methyl alcohol may be obtained from wood spirit by saturating with fused CaCl₂ and heating on a water bath The residue is a compound of methyl alcohol with CaCl₂, which when distilled with water is decomposed, giving off the methyl alcohol The distillate is then rectified over quicklime (Kane, *A* 19, 164) According to Gould (*C J* 7, 811) it is best to distil the wood spirit with conc NaOHaq (to saponify MeOAc) and then to dehydrate with K₂CO₃ before saturating with CaCl₂ A better method for obtaining methyl alcohol from wood spirit is to distil the spirit (1 pt) with H₂SO₄ (1 pt) and potassium oxalate (2 pts), the crystalline di-methyl oxalate is then decomposed by distillation with water, and the MeOH dried over lime (Wöhler, *A* 81, 376) The oxalate may also be obtained by dissolving oxalic acid, dehydrated at 100°, in boiling MeOH, leaving the solution to cool, and washing the crystals with cold water as long as the filtrate exhibits the iodoform reaction (Erlenmeyer, *N Rep Pharm*, 28, 624). An alternative method consists in passing HCl into a solution of benzoic acid in wood spirit, distilling, ppg with water the portion collected above 100°, decomposing by boiling for several hours with aqueous NaOH, distilling, and rectifying over quicklime (Carius, *A*, 110, 210). The following modification of Wöhler's process is recommended by Britmar a. Fawcitt (*Tr E* 38, 509) 100 c.c of wood spirit are digested with 150 g of powdered NaOH, and then distilled on a water-bath, 500 g. of oxalic acid crystals are mixed with 200 c.c. of sulphuric acid, and then 400 c.c. of the alcohol, purified as above, is added, and the whole cautiously heated on a

water-bath The methyl oxalate thus obtained is thoroughly dried by pressure, and the alcohol regenerated by digestion with water at 70°. To dehydrate the alcohol thus obtained, digestion with baryta, lime, and dried copper sulphate is necessary. Even when prepared from the oxalate methyl alcohol is not quite pure, as it contains bodies which exhibit Lieben's iodoform reaction. It may be freed from these by dissolving in it one tenth of its weight of iodine, gradually adding NaOH until the liquid is distinctly alkaline, and distilling. The product, rectified over CaO, has a specific gravity of 81 at 15° (Regnault & Villejean, *A Ch* [6] 4, 430, *C R* 99, 82). Methyl alcohol may also be prepared by saponifying methyl formate (8 pts.) with NaOH (2 pts.) and water (6 pts.) (Grodzky, *A Kramer*, *B* 9, 1928, Baidy & Bordet, *A Ch* [5] 16, 564). Methyl alcohol may be obtained very nearly pure by distilling oil of winter green with potash, and rectifying the distillate over lime.

Properties—Colourless mobile liquid, with purely spirituous odour. Burns with a pale flame. Mixes with water, alcohol, and ether, dissolves fixed and volatile oils and most resins. Hence it is much used as a solvent. In aqueous solution it produces intoxication, in concentrated solution it is poisonous. When perfectly dry it dissolves a little CuSO_4 , acquiring a bluish green colour, but it does not dissolve crystallised $\text{CuSO}_4 \cdot 7\text{aq}$ (Klepl, *J pr* [2] 25, 526). Methyl alcohol is etherified by acetic acid more rapidly and completely than any other alcohol (Menschutkin, *Z P C* 1, 611). Dittmar & Fawsitt give the specific gravity of mixtures of methyl alcohol and water as follows:

Pct. of CH_3OH	Sp. gr. at 15°	Sp. gr. at 15.56°
0	99907	99907
10	98429	98262
20	97233	96808
30	96057	95467
40	9457	93697
50	92873	91855
60	90917	89799
70	88687	87487
80	86314	85035
90	83751	82396
100	81015	79589

Older determinations are by Ure (*P M* [3] 19, 51), Dupré (*Pr* 20, 336), and Duclaux (*A Ch* [5] 13, 87). The same observers find the vapour tension of methyl alcohol, measured in millimetres of mercury at 0°, to be

Temp	Tension	Temp	Tension
0	29.7	40	259.4
10	53.8	50	409.4
20	94.0	60	624.3
30	158.9	64.96	760.0

(cf. Kononoff, *P* [2] 14, 40). The following vapour tensions are given by Richardson (*C J* 49, 762)

Temp	Tension	Temp	Tension
-8.3	17.8	39.2	235.13
+0.7	32.06	49.2	370.26
11.2	55.82	59.9	584.24
22.7	108.96	65.7	753.05
30.2	155.32		

Vol. III.

The specific heat of aqueous methyl alcohol was found by Dupré to be as follows—

Weight p.c. of methyl alcohol	Specific heat	Weight p.c. of methyl alcohol	Specific heat
10	98582	60	80177
20	95914	70	75500
30	92658	80	69999
40	89219	90	64282
50	84645	100	54325

Estimation—Pure methyl alcohol does not give Lieben's iodoform reaction with iodine and potash.

The amount of methyl alcohol in commercial wood spirit may be estimated by adding 5 c.c. of the spirit, drop by drop, to 30 g. of PI_2 in a flask provided with inverted condenser. The flask is then heated for 5 minutes in boiling water, and the MeI then distilled off by inclining the condenser. The volume of MeI is read off in a graduated receiver 5 c.c. of methyl alcohol yield 7.19 c.c. of methyl iodide (Krell, *B* 6, 1310, cf. Grodzky & Kramer, *B* 7, 1495, 9, 1928). If it is desired to determine how much of the methyl alcohol is in the form of MeOAc , the spirit may be boiled with standard alkali, and the amount used up in the saponification determined.

Baidy and Bordet (*A Ch* [5] 16, 565) modify Krell's process, using only 15 g. of PI to 5 c.c. of wood spirit, but adding 5 c.c. of aqueous HI subsequently. They distil the liquid at 90°–90°, and at the end of the distillation add 5 c.c. of water and quickly distil. The methyl iodide is washed once or twice with water and measured. Di methyl ortho acetic aldehyde or methyl acetal $\text{CH}_3\text{CH}(\text{OMe})_2$ boils at 64° and gives MeI on treatment with PI_2 , but it does not react with aniline, so that when the wood spirit is to be used in preparing di methyl aniline, by heating with aniline hydrochloride, the estimation by PI_2 will give too high results.

The presence of acetone is objectionable in methyl alcohol that is to be used for preparing di methyl aniline. Its amount can be determined by shaking 1 or 2 c.c. of the alcohol with 20 or 30 c.c. of normal aqueous KOH, adding 20 or 30 c.c. of a decinormal solution of iodine, until the solution is clear. The liquid is then acidified with HCl (SG 1.025), excess of decinormal sodium thiosulphate added, and the excess determined by titrating back with iodine solution. If 1 c.c. of methyl alcohol be taken, the weight of acetone in 100 c.c. will be found by multiplying the amount of iodine used up by 7.612 (Messinger, *B* 21, 3366, cf. Kramer, *B* 13, 1002, Hintz, *Fr* 27, 182).

The estimation of methyl alcohol in ethyl alcohol can be effected by oxidation with a standard solution of $\text{K}_2\text{Cr}_2\text{O}_7$, for 1 pt. of ethyl alcohol reduces 4.278 pts. of the dichromate in becoming oxidised to acetic acid, while 1 pt. of methyl alcohol, in being oxidised to CO_2 , and water, reduces 9.224 pts. of $\text{K}_2\text{Cr}_2\text{O}_7$. A solution of 80 g. $\text{K}_2\text{Cr}_2\text{O}_7$ and 150 c.c. H_2SO_4 per litre is employed, and the unreacted chromate estimated volumetrically (O. Hehner, *An* 12, 25).

When 10 c.c. of pure ethyl alcohol are shaken with 1 c.c. of a 1 p.c. solution of KMnO_4 at 20°, no reduction takes place for 20 minutes, but if the ethyl alcohol contains crude wood

spirit, decolourisation takes place at once (Haber mann, *Fr* 27, 668)

Reactions — 1 Passage through a red hot tube yields acetylene and other products (Berthelot, *C R* 50, 805) — 2 In contact with platinum black and air it is oxidised to formic aldehyde and formic acid — 3 Heated with ammonium chloride in a sealed tube at 300° it yields mono-, di-, and tri methylamine (Berthelot) — 4 Bleaching powder does not yield chloroform (Goldberg, *J pr* [2] 24, 115) — 5 Potassium gives off hydrogen, forming KOMe — 6 When its vapour is passed over heated potash, hydrogen is given off, and potassium formate, oxalate, and carbonate are successively formed — 7 Conc H₂SO₄ forms HMeSO₄, which, when heated with excess of methyl alcohol, yields di methyl oxide When distilled with excess of H₂SO₄ di methyl sulphate passes over — 8 Converted into methyl chloride by treatment with HCl, with PCl₅, or with S₂Cl₂ The joint action of H₂SO₄ and HBr gives rise to methyl bromide and ethyl bromide (Niemilovitch, *M* 10, 820) — 9 SOCl₂ forms MeSH, Me₂SO, MeCl, and other products (Carius, *A* 111, 93) — 10 SO₂ forms CH(OH)(SO₂H)₂ (Max Muller, *B* 6, 1031) — 11 When acidulated with 5 p.c sulphuric acid and submitted to electrolysis it forms CO₂, CO, methyl formate, methyl sulphate, and methylal (Renard, *C R* 80, 236) — 12 Distillation over heated *vinc dust* splits it up into CO and hydrogen, a very little methane being also formed (Jahn, *B* 13, 983, *M* 1, 378) — 13 Zinc chloride forms CH₄, water, Me₂O, hexa methylbenzene, and traces of propylene, butylene, and other hydrocarbons (Le Bel a Greene, *C R* 87, 260, 89, 413) — 14 Aldehyde (1 vol), MeOH (2 vols), and HCl form CH₃CH(OMe)₂ (Claus a Trauer, *B* 19, 3004) — 15 Not affected by *B aceti* growing in solutions containing it (Brown, *C J* 49, 177) — 16 Converts *m* and *p* diazo benzoic acid into C₆H₅(OMe)CO₂H, while *o* diazo benzoic acid only gives benzoic acid (Griess, *B* 21, 978) — 17 When heated with hydrochlorides of aromatic bases (e.g. aniline, xylylidine, piperidine) it often displaces hydrogen in the nucleus by methyl (Hofmann, *B* 15, 2895, Ladenburg, *B* 16, 2057) — 18 Unlike EtOH, it hardly reacts when heated with phenol and ZnCl₂ (Auer, *B* 17, 669) — 19 Unlike butyl and amyl alcohols, it does not form a homologue of benzene when heated with benzene and ZnCl₂ at 270° (Goldschmidt, *B* 15, 1066) — 20 ClCONH₂ forms methyl allophanate NH₂CO NH CO₂Me [208°] (Gattermann, *A* 244, 40)

Metallic derivatives — KOMe Obtained by dissolving K in methyl alcohol — (KOH)₂(MeOH)₂ or (KOMe)₂(MeOH)₂ 3aq [c 110°] Obtained by evaporating a solution of KOH in methyl alcohol (Göttig, *B* 21, 1832) Large elastic plates, somewhat heavier than water, on which they move about rapidly, being decomposed — (NaOH)₂(MeOH)₂ or (NaOMe)₂MeOH aq Obtained by dissolving NaOH in dry MeOH and evaporating Crystalline mass, which moves about on the surface of water while decomposing and dissolving — NaOMe 13aq Obtained by evaporating a solution of NaOH in not quite dry methyl alcohol (Göttig, *B* 21, 561) — NaOMe(MeOH)₂ (Fröhlich, *A* 202, 295) CO passed over NaOMe at 160°

forms acetic acid CO passed into a hot mixture of NaOMe and NaOAc forms propionic acid (Geuther a Fröhlich, *A* 202, 312) When distilled with the Ba salt of a carboxylic acid it displaces the carboxyl by hydrogen Thus succinic acid may be converted into propionic acid (Mai, *B* 22, 2135) — TIOME From TIOEt and excess of MeOH (Lamy, *J* 1864, 466) — (Ba(OMe))₂BaO.H₂O aq White nacreous plates, obtained by evaporating at 135° a solution of BaO in MeOH (De Forcrand, *C R* 102, 1397, 1557) Perhaps identical with Ba(OMe) aq described by Dumas and Paillet (*A Ch* 58, 17) 1 litre of MeOH dissolves 200 g of BaO The heat of formation of the compound from solid 3BaO and liquid 4MeOH is 62,500 If a considerable quantity of water is added to the solution of BaO in MeOH the hydrate BaO 10aq is precipitated The compound BaO2Ba(OMe)₂ 2aq is readily formed, even if as much as 3 p.c water be present in the methyl alcohol, but by evaporating in the cold over H₂SO₄ crystals of Ba(OMe) 3aq are formed These are sol water and alcohol By passing HCN into a solution of baryta in methyl alcohol there is formed barium cyanomethylate Ba(OMe)CN.MeOH This is a crystalline powder, sol water, less sol methyl alcohol It loses at 100° the methyl alcohol of crystallisation

Combinations — CaCl₂ 4MeOH Methyl alcohol dissolves CaCl₂ with great rise of temperature, and on cooling this compound separates in large six sided tables (Kane, *A* 19, 168) It is not decomposed at 100°, but water readily liberates the MeOH — LiCl 3MeOH — MgCl₂ 6MeOH (Simon, *J pr* [2] 20, 377) — SbCl₅MeOH [81°] Slightly yellow crystals (from hot alcohol), decomposes at 130°, giving off MeCl and HCl (W C Williams, *C J* 30, 463) — CuSO₄ 2MeOH Minute bluish green crystals, obtained by shaking anhydrous CuSO₄ with methyl alcohol (Forcrand, *C R* 102, 551)

METHYL ALDEHYDE is FORMIC ALDEHYDE
METHYL - ALIZARIN v DI OXY METHYL

ANTHRAQUINONE

METHYL-ALLANTOIN C₄H₇N₃O₃ [225°] Formed by oxidising methyl uric acid with cold aqueous KMnO₄ (Hill, *B* 9, 1090) Monoclinic prisms, decomposed by fusion V sol hot water, sl sol alcohol, insol ether Conc HIAq splits it up into urea and methyl hydantoin — AgC₄H₃N₃O₃ prisms, sl sol cold water

METHYL-ALLOXAN C₄H₅N₃O₄ 1c

CO < NH CO > CO Formed by oxidising methyl uric acid with HNO₃ or with KClO₃ and HCl (Hill, *B* 9, 1092) Formed also by treating theobromine (2 pts) with KClO₃ (9 pts) and HCl (S G 106) at 50° (Maly a Andreasch, *M* 3, 108, cf Fischer, *A* 215, 304) It is converted by alkalis into methyl alloxanic acid, and by boiling HNO₃ into methyl parabanic acid H₂S forms di methyl alloxantin KHSO₄ forms a compound B'KHSO₄ aq, which crystallises in large monoclinic prisms

Di methyl alloxan C₄H₇N₃O₄ 1c

CO < NMe CO > CO A product of the action of KClO₃ and HCl on caffeine at 50° It is extracted by ether (E Fischer, *A* 215, 257, Maly a Andreasch, *M* 3, 92) Colourless six sided

tables (containing 2aq), which slowly turn red in air. V sol water, almost insol alcohol, insol ether. Dyes the skin red. With FeSO_4 and ammonia it gives a characteristic indigo colouration. After drying over H_2SO_4 , it is left as an amorphous powder (containing aq), sol alcohol and ether. Di methyl alloxan decomposes at 100° . It prevents the ppn of cupric and ferric salts by potash. Hydrogen sulphide converts it into amalic acid. KHSO_4 forms the compound $\text{C}_4\text{H}_4\text{N}_2\text{O}_4\text{KHSO}_4$, which crystallises in long tables, $S 7.2$ at 20° , almost insol alcohol, insol ether. This compound may be crystallised from warm water, and does not give the indigo colouration with FeSO_4 and ammonia.

METHYL ALLOXANIC ACID $\text{C}_4\text{H}_4\text{N}_2\text{O}_5$. Formed by the action of alkalis on methyl-alloxan. When the product of the action of HNO_3 on methyl uric acid is neutralised with CaCO_3 , and then mixed with alcohol and ammonia the salt $\text{CaC}_4\text{H}_4\text{N}_2\text{O}_5$ is ppd (Hill, *B* 9, 1092). This salt is gelatinous, and when boiled with water it gives off methylamine.

METHYL-ALLOXANTIN $\text{C}_4\text{H}_4\text{N}_2\text{O}_5$. Obtained by mixing solutions of diuric acid and methyl alloxan (Andreasch, *M* 3, 431). Crystallises from water in minute thin tables (containing 3aq).

s Di methyl alloxantin $\text{C}_{10}\text{H}_{10}\text{N}_4\text{O}_5$ &c

Formed by passing H_2S into an aqueous solution of methyl alloxan (Maly & Andreasch, *M* 3, 109). Thin plates (containing 4aq), almost insol alcohol and ether, sl sol cold water. Turns red in air. Gives a red colouration with ammonia, and a violet colouration with potash or baryta (Andreasch, *M* 3, 109).

u Di-methyl alloxantin

Formed by reducing di methyl alloxan to di methyl dialuric acid, and ppg the aqueous solution of this acid with alloxan (Andreasch, *M* 3, 428). Crystallises from hot water in minute four sided pyramids (containing aq), insol alcohol and ether.

Tetra methyl alloxantin v AMALIC ACID

METHYL ALLYL v BUTYLENE

METHYL-ALLYL ACETO ACETIC ACID v ACETO ACETIC ACID

DI METHYL-ALLYL-AMINE *Methylol codida* $\text{C}_4\text{H}_8\text{NMe}_2$. From allylamine and MeI (Bono, *B* 20, Ref 137). When distilled with KOH it yields NMe_3 and an aldehyde $\text{C}_4\text{H}_8\text{O}$ (130° - 135°).

p **METHYL-ALLYL BENZENE** $\text{C}_{10}\text{H}_{12}$ &c $\text{CH}_3\text{C}_6\text{H}_4\text{C}_3\text{H}_5$ p *Allyl toluene* (192°). Formed from cymene by chlorinating and heating the resulting $\text{CH}_3\text{C}_6\text{H}_4\text{C}_3\text{H}_5\text{Cl}$ with alcoholic KOH (Errera, *G* 14, 283, 505). Liquid. Combines with bromine KMnO_4 oxidises it to p toluic acid. HBrAq ($S 1.59$) at 200° forms a polymeride ($\text{C}_{10}\text{H}_{12}$) (350°), and this on keeping changes to an amorphous solid, which by distillation is reconverted into p methyl-allylbenzene.

METHYL-DI-ALLYL-CARBINOL v OCTINYL ALCOHOL

Di methyl allyl-carbinol v. HEXENYL ALCOHOL.

METHYL-ALLYL-CHLORACETOL v DI-CHLORO HEXYLENE

METHYL ALLYL ETHER v METHYL ALLYL OXIDE

METHYL ALLYL DIKETONE $\text{C}_8\text{H}_{10}\text{O}_4$ &c $\text{CH}_3\text{COCOCH}_2\text{C}_6\text{H}_5$ *Acetyl crotonyl* ($c 130^\circ$). Obtained by distilling its mono oxim with dilute H_2SO_4 (Otte & Von Pechmann, *B* 22, 2124). Yellow oil with irritating odour. Not obtained pure.

Mono oxim $\text{CH}_3\text{COO}(\text{NOH})\text{C}_6\text{H}_5$ *Nitroso-allylacetone* *Methyl nitroso butenyl ketone* (146°). From allyl aceto acetic acid and nitrous acid. White plates (from ligroin), v sol usual menstrua. Its solution in NaOHAq is yellow.

Di oxim $\text{CH}_3\text{C}(\text{NOH})\text{C}(\text{NOH})\text{C}_6\text{H}_5$ (135°). Formed from the mono oxim by warming with hydroxylamine. Small plates.

Phenyl hydrazide oxim $\text{CH}_3\text{C}(\text{N}(\text{HPh})\text{C}(\text{NOH})\text{C}_6\text{H}_5$ (137°). Brownish-red needles (from benzene and ligroin).

METHYL ALLYL OXIDE $\text{C}_4\text{H}_6\text{O}$ &c $\text{CH}_3\text{OCH}_2\text{C}_3\text{H}_5$ *Allyl methyl ether* (46°) $S 8.11$ 77 $H F p 34.080$ $H F v 32.050$. From allyl bromide and NaOMe (Henry, *B* 5, 455). With bromine it forms $\text{CH}_3\text{OCH}_2\text{CHBrCH}_2\text{Br}$ (185°). ICl gives $\text{CH}_3\text{OCH}_2\text{CHCl}$ (196°) (Silva, *B* 8, 1469).

METHYL ALLYL PROPYL CARBINOL v OCTENYL ALCOHOL

METHYL ALLYL SULPHIDE $\text{C}_6\text{H}_8\text{S}$ &c $\text{CH}_3\text{SC}_3\text{H}_5$ ($c 92^\circ$) $V D 43.36$. Formed by heating lead methyl mercaptide $(\text{CH}_3\text{S})_2\text{Pb}$ with allyl bromide and ether at 100° (Obermayer, *B* 20, 2925).

METHYL ALLYL THIO-UREA

$\text{CH}_3\text{NHCSNHCH}_2\text{C}_3\text{H}_5$ (50.5°). Formed from allylamine and methyl thio carbimide or from methylamine and allyl thio carbimide (O Hecht, *B* 23, 286). White mass.

METHYL AMIDO ACETIC ACID $\text{C}_4\text{H}_7\text{NO}_3$ &c $\text{CH}_3\text{NHCH}_2\text{CO}_2\text{H}$ *Methyl glycolic* *Sarcosine* $Mol w 89$ (210° - 215°). Formed by the action of boiling baryta water on creatine or caffeine (Liebig, *A* 62, 310, Rosengarten & Strecker, *A* 157, 1, Schilling, *C* C 1884, 811). Formed also by heating chloro acetic ether with aqueous methylamine at 125° (Volhard, *A* 123, 261).

Properties — Trimetric prisms, v e sol water, sl sol alcohol. Has a somewhat sweet taste. Heated to 210° - 220° the greater part evolves H_2O giving the anhydride $\text{C}_4\text{H}_7\text{N}_2\text{O}_2$, whilst a smaller portion splits up into di methyl amine and CO_2 (Mylus, *B* 17, 286). Chloride of cyanogen passed into the fused substance gives methyl hydantoin and sacosine-anhydride (Traube, *B* 15, 2110). When taken internally, the greater part passes as such into the urine (Baumann & Mering, *B* 8, 587, Salkowski, *H* 4, 107, Schiffer, *H* 5, 266). Nitrous acid passed into its hot aqueous solution forms a nitroso-derivative $\text{CH}_3\text{N}(\text{NO})\text{CH}_2\text{CO}_2\text{H}$, which is a thick liquid, forming the salt CaA^+ , aq crystallising in needles (Schultzen, *Z* 1867, 616). Gives methyl uric acid when heated with urea (Horbaczewski, *M* 6, 356).

Salts — $(\text{C}_4\text{H}_7\text{NO}_3)_2\text{Cu}$ 2aq ultramarine blue crystals (*E* Schmidt, *A* 217, 273) — $\text{C}_4\text{H}_7\text{NO}_3\text{HCl}$ needles (from alcohol) — $(\text{C}_4\text{H}_7\text{NO}_3)_2\text{ZnH}_2\text{O}$ 8 (alcohol) 038 V e. sol water (Bulginsky, *J*.

1867, 495) — $(C_2H_5NO)_2H_2PtCl_2$, 2aq monoclinic tables, $a b c = 1.0381 \ 1 \ 0.747$, $\beta = 75^\circ 27'$ — $C_2H_5NO \cdot H_2AuCl_4$, yellow needles, sl sol cold water — $C_2H_5NO \cdot HNO_3$, [c 70°] Very hygroscopic, v sol cold alcohol (Franchimont, *R T C* 2, 839) — $(C_2H_5NO)_2H_2SO_4$, aq four sided tables, v e sol water *S* (boiling alcohol) 10

Guanidine hydrochloride

$C_2H_5NO \cdot HClCH_2N_2$. Formed by heating methyl-amido acetic acid with guanidine hydrochloride (Baumann, *B* 7, 1151) Tables (from alcohol)

Anhydride $C_2H_5N_2O_2$, *e*

$CH_3 \cdot N \cdot CH_2 \cdot CO$

$\begin{array}{c} | \\ OC \cdot CH_2 \cdot N \cdot CH_3 \end{array}$ (?) *Sarcosine anhydride*

[150°] Formed by the action of cyanogen chloride on melted sarcosine Prepared by heating sarcosine to 210° – 220° and distilling the residue (Traube, *B* 15, 2112, Mylius, *B* 17, 286) Colourless prisms V sol water, al cohoh, and ether Bitter taste Weak base By boiling with water it again gives sarcosine On oxidation with $KMnO_4$ it yields *s di methyl oxamide*

Salts — $B'_2H_2Cl_2PtCl_2$, 2aq prisms — $B'_2H_2Cl_2PtCl_4$, 4aq large six sided tables — $B'_2HClAuCl_4$, 2aq prisms

Sarcosine-uric acid $C_5H_8O_8N_4$. Obtained by heating a mixture of sarcosine (3 pts) and uric acid (2 pts) at 210° , a good yield is obtained

Properties — Colourless prismatic crystals (containing 2aq) Sol hot water It shows the murexide reaction It slowly reduces alkaline solutions of copper It has weak acid and basic properties, dissolving in aqueous acids and alkalis By fusion with KOH at 110° it is resolved into uric acid and sarcosine Heated with bromine water it is converted into bromo sarcosine-mesouric acid $C_5H_8N_4O_8Br$

Salts — The acetate forms microscopic crystals, sl sol hot acetic acid, insol cold $HOAc$, v sol water The formate is very analogous to the acetate The ammonium salt is crystalline — $A''Ag$, insol white amorphous pp (Mylius, *B* 17, 518)

Bromo-sarcosine mesouric acid $C_5H_8N_4O_8Br$ Formed by digesting a warm aqueous solution of sarcosine uric acid with bromine, which gives a nearly theoretical yield (Mylius, *B* 17, 521) Heavy colourless tables Sl sol water By H_2S it is reduced to sarcosine mesouric acid It is readily decomposed by alkalis, but is stable towards acids

Sarcosine-mesouric acid $C_5H_8O_8N_4$ Obtained by reducing a hot aqueous solution of bromo sarcosine mesouric acid with H_2S (Mylius, *B* 17, 524) Trimetric tables or needles V sol water, insol alcohol It is a strong acid, but also possesses weak basic properties By bromine water it is reconverted into the bromo derivative, similarly chlorine water gives the chloro-derivative It is very oxidisable, reducing $AuCl_3$, alkaline, copper solution, $KMnO_4$, &c, very readily

Salts — The acetate forms an unstable crystalline pp, sl sol acetic acid — $A''HNH$, fine needles, v sol water — $A''Ag$, white amorphous pp

Tri-methyl-amido acetic acid internal anhydride *v* BETAIN.

DI-METHYL-AMIDO ACETIC ORTHALDE

HYDE *Methylo-hydroxide* C_2H_5NO , *e* $CH(NMe_2OH)CH(OH)_2$. *Muscarine* Occurs, together with neurine, in the fly agaric (Schmie deberg a Koppe, *J* 1870, 875) Formed from neurine by oxidation with conc HNO_3 (Schmie deberg a Harnack, *J* 1876, 804) Deliquescent crystalline mass, sol alcohol Alkaline in reaction Active narcotic poison Separated from neurine by placing the mixed hydrochlorides on filter paper, when the muscarine salt deliquesces and is absorbed by the paper (Harnack, *J* 1876, 803) — $B'(C_2H_5NOCl)_2PtCl_2$, 2an — $C_2H_5NO \cdot AuCl_3$

Di-ethyl derivative of the methylo hydroxide C_2H_5NO , *e*

$CH_3(NMe_2OH)CH(OEt)_2$ *Hydroxide of tri-methyl-amido-acetal* When chloro acetal $CH_2ClCH(OEt)_2$ is treated with tri-methyl amine there is formed $CH_3(NMe_2Cl)CH(OEt)_2$ and C_2H_5NOCl , which is probably $CH_3(NMe_2Cl)CHO$ The two salts are separated by fractional ppn by platinum chloride — $(C_2H_5NOCl)_2PtCl_2$, orange crystals, sl sol cold water — $C_2H_5NO \cdot AuCl_3$, lemon yellow needles

Di-methyl amido acetic aldehyde *Methylo hydroxide* C_2H_5NO , *e* $CH_3(NMe_2OH)CHO$ Formed by saponifying $CH_3(NMe_2OH)CH(OEt)_2$ with baryta (Berlnerblau, *B* 17, 1142) The hydrochloride C_2H_5NOCl is also formed as above Gives the aldehyde reactions — *Platinochloride* $(C_2H_5NOCl)_2PtCl_2$, octahedra (from dilute alcohol)

DI METHYL-AMIDO-ACETONE *Methylo-chloride* C_2H_5NOCl , *e* $CH_3COCH_2NMe_2Cl$ *Caprine chloride* Formed by the action of dry NMe_3 upon chloro acetone in the cold (Niementovitch, *M* 7, 241) Very deliquescent shining needles, sol alcohol Gives the alkaloidal reactions Acts physiologically like curare — $C_2H_5NOClAuCl_3$, [189°]

p DI-METHYL-AMIDO-ACETOPHENONE $C_6H_5(NMe_2)COCH_3$, [59°] Formed by methylation of *p* amido acetophenone (Klingner, *B* 18, 2694) Yellowish plates (from hot water) V sol alcohol, ether, and hot water

o DIMETHYL AMIDO ANISOL. *v* *o* Di-METHYL-AMIDO PHENOL *methyl ether*

METHYL AMIDO-AZO-COMPOUNDS. *Azo-*COMPOUNDS

METHYL AMIDO BENZAMIDE *v* *Amide of* METHYL AMIDO BENZOIC ACID

METHYL-AMIDO BENZENE *v* METHYL-ANILINE and TOLUIDINE

Di-methyl-amido-benzene *v* XALIDINE, METHYL TOLUIDINE, and DI METHYL-ANILINE

Tri-methyl amido benzene *v* MESIDINE and ψ CUMIDINE

Tetra-methyl amido-benzene *v* TETRA

METHYL PHENYL AMINE

Tetra methyl di amido benzene *v* TETRA

METHYL-PHENYLENE DIAMINE

Di-methyl-tri-amido-benzene

$C_6H_5(NMe_2)(NH_2)_2$, [184°] [44°] (298°) Needles. Readily turned blue in the air Prepared by reduction of dinitro dimethyl aniline [87°] Formed also by reduction of nitro-*p* dimethyl amido-phenyl oxamic ether

Acetyl derivative

$C_6H_5(NMe_2)(NH_2)(NHAc)$ [158°] Prisms (containing aq) (Wurster a Sendtner, *B* 12, 1805).

***u*-Tri-methyl-tri-amido-benzene**

$C_6H_3(NMe_2)(NH_2)(NHMe)$ [1 z 4] [90°] (294°)
Prepared by reduction of the nitrosamine derived from nitro trimethyl *p*-phenylene diamine (Wurster a Schobig, *B* 12, 1812) White needles Sol water Gives a blue colouration with HNO_3

Diacetyl derivative [184°] Leaflets

METHYL-AMIDO-BENZENE-AZO- COMPOUNDS v Azo- COMPOUNDS and Dis azo- COMPOUNDS**DI-METHYL-AMIDO-BENZENE PHOSPHINIC ACID** $NMe_2, C_6H_4, P(OH)_2$ [162°]

Formed by decomposing its chloride with water (Schenk a Michaelis, *B* 21, 1498) White needles, v sol hot water and alcohol On boiling its aqueous solution it is split up into di-methyl aniline and phosphorous acid When heated alone it gives phosphorus, PH_3 , and di-methyl aniline

Salt— $NaHA''$ 2aq large crystals (from alcohol)

Chloride NMe_2, C_6H_4, PCl_2 [66°] (250° at 120 mm) Formed by the action of PCl_3 (100 g) on di-methyl aniline (70 g) in presence of $AlCl_3$ (20 g) The mixture is boiled for eight hours with inverted condenser, and the product extracted with petroleum ether and distilled *in vacuo* Thin plates, v sol benzene, m sol ether, sl sol petroleum ether Converted by the action of chloro benzene and sodium into di-methyl amido tri phenyl phosphine

DI-METHYL AMIDO BENZENE PHOSPHONIC ACID $NMe_2, C_6H_4, PO(OH)_2$ [133°]
Formed by oxidising $NMe_2, C_6H_4, P(OH)_2$ with $HgCl_2$ (Schenk a Michaelis, *B* 21, 1500) Crystals, v e sol water and alcohol

METHYL AMIDO BENZENE SULPHONIC ACID $C_6H_4NSO_3, v e NHMe, C_6H_4, SO_3H$ Formed, together with methane disulphonic acid, by heating the acetyl derivative of methyl aniline with H_2SO_4 at 145° (Smyth, *B* 7, 1240) Crystals, which decompose at 182° without previous fusion — BaA', aq crystalline powder

Methyl-amido-benzene sulphonic acid
 $NHMe, C_6H_4, SO_3H$ Formed by heating methyl-aniline ethyl sulphate at 210° (Mundelius *B* 7, 1350) Plates (containing aq), insol alcohol and ether — $BaA', 3' aq$ small prisms — $CaA' 4aq$ — $PbA', 8aq$

Di-methyl-amido-benzene *p*-sulphonic acid
 NMe_2, C_6H_4, SO_3H [150°] (S), [257°] (V a G)

Formation —1 By heating di-methyl aniline with rather more than the equivalent quantity of sulphuric acid at 185° (Smyth, *B* 6, 344, 7, 1237, Armstrong, *B* 6, 663, Vignon, *C R* 107, 263) —2 From di-methyl aniline and $ClSO_2Et$ (Wenghoffer, *J pr* [2] 16, 448) —3 From bromo-di-methyl-aniline and H_2SO_4 at 180° (Michler a. Walder, *B* 14, 2177) —4 From di-methyl aniline and $SOCl_2$ followed by water (Michaelis a Godchaux, *B* 23, 555)

Properties —8 sided prisms (containing aq). Decomposes at 230°

Salts — $BaA', 3aq$ needles or plates — $BaA', 5aq$ (Vignon) — $BaA', 11aq$ efflorescent trichinic crystals (Laar, *J pr* [2] 20, 262) — $NaA' 2aq$ Long needles, m sol water, sl sol aqueous $NaOH$, insol water (M a G.)

Chloride $C_6H_4(NMe_2)_2SO_2Cl$

Ethyl ether EtA' [85°] Formed from alcohol and the chloride

Di-methyl-amido-benzene *p*-sulphonic acid Anhydride of the methylo hydroxide

$C_6H_3NSO_3, v e C_6H_4, < \begin{smallmatrix} NMe_2 \\ SO_2 \end{smallmatrix} > O$ Formed by allowing a mixture of amido benzene *p*-sulphonic acid, MeI , conc KOH aq, and $MeOH$ to stand for some time in the cold (Griess, *B* 12, 2116) Four sided plates, v sol cold water, almost insol alcohol, insol ether Decomposes before fusion Ppd as periodide by a solution of iodine in $HIAq$ —
 $(SO_2, H_2C_6H_4, NMe_2, Cl), PtCl_3, 8aq$ orange tables, v e sol cold water

METHYL-*o*-AMIDO-BENZOIC ACID

Amide $NHMe, C_6H_4, CONH_2$ [160°] Formed by heating *o* amido benzamide with MeI at 100° (Weddige, *J pr* [2] 36, 152) Plates, v sol hot alcohol, sol water In dilute solutions it shows blue fluorescence

Acetyl derivative

$NHMe, C_6H_4, CO NHAc$ [155°] Long needles, v sol hot alcohol, sl sol benzene and ether When heated above 155° it forms the anhydro derivative $C_6H_4, < \begin{smallmatrix} CO \\ NMe \end{smallmatrix} > CMe$ [199°] which is an oxy di-methyl quinoxaline

Nitroso derivative of the amide

$NO NMe, C_6H_4, CO NH_2$ [149°] Pale yellow prisms (from hot alcohol) (Finger, *J pr* [2] 37, 431)

Methyl-*m*-amido-benzoic acid $C_6H_4NO_2, v e NHMe, C_6H_4, CO_2H$ Formed by boiling (a)-benzcreatin $NH, C(NH)NMe, C_6H_4, CO_2H$ with baryta water (Griess, *B* 8, 325) Nodular groups of plates, v sol hot water Nitrous acid ppts a nitroso-derivative Salt — $C_6H_4NO_2, HCl$ six-sided plates

Di-methyl-*m*-amido-benzoic acid $C_6H_4NO_2, v e NMe_2, C_6H_4, CO_2H$ [151°] Obtained by saponifying its methyl ether Needles, sl sol hot water

Methyl ether NMe_2, C_6H_4, CO_2Me (270° uncor) Obtained by fusing the isomeric anhydride of the methylo hydroxide (*v infra*) (Griess, *B* 6, 587) Heavy yellowish oil, sol acids — $C_6H_4, MeNO_2, H_2SO_4$ very small prisms, sl sol dilute sulphuric acid, v sol water — $(C_6H_4, MeNO_2), H, PtCl_3$ spindle shaped laminae, v sl sol cold water

Anhydride of the methylo-hydroxide

$C_6H_3NO_3, v e C_6H_4, < \begin{smallmatrix} NMe_2 \\ CO \end{smallmatrix} > O$ *Benzetaine*
Formed by allowing a mixture of *m* amido benzoic acid with $MeOH$ (1 mol), aqueous KOH (3 mols), and MeI (3 mols) to stand in the cold, the product, after freeing from $MeOH$ by distillation, being saturated with HI , whereupon the iodide NMe_2, I, C_6H_4, CO_2H is ppd This iodide is then boiled with water and lead hydroxide (Griess) Small deliquescent needles (containing aq), which give up their water of crystallisation at 105° V e sol cold alcohol, insol ether Tastes bitter and is neutral in reaction Forms $(NMe_2, Cl, C_6H_4, CO_2H), PtCl_3, 4aq$ crystallising in large prisms, sl sol hot water

Methylo iodide NMe_2, I, C_6H_4, CO_2H Formed as above Small short prisms (containing aq), sl sol cold water

Methylo-chloride NMe_2, Cl, C_6H_4, CO_2H

Monoclinic crystals, a b c = 1.939 1 0.876, β = 88° 49' (Zingel, *Z* *K* 10, 414)

Di-methyl-*p*-amido-benzoic acid

$\text{NMe}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ [235°] Formed by boiling its chloride with water. Prepared by boiling for three hours a mixture of *p* amido benzoic acid (1 mol), MeI (2 mols), and aqueous KOH (3 mols) dissolved in methyl alcohol (Michler, *B* 9, 400). Obtained also by heating tetra methyl-di amido benzophenone with soda lime at 340°, extracting the product with hot water, and ppg by acetic acid (E Bischoff, *B* 22, 341). Short needles (from alcohol), sol aqueous KOH and HClAq , insol dilute acetic acid. Nitrous acid forms $\text{NMe}_2\text{C}_6\text{H}_4(\text{NO})\text{CO}_2\text{H}$ [224°]. The Ca salt forms yellowish plates.

Methyl ether $\text{NMe}_2\text{C}_6\text{H}_4\text{CO}_2\text{Me}$ [103°] Silvery plates (from alcohol), *v* sol benzene, ether, and chloroform, *m* sol dilute alcohol. Nitrous acid forms $\text{NMe}_2\text{C}_6\text{H}_4(\text{NO})\text{CO}_2\text{Me}$ [101°].

Chloride $\text{NMe}_2\text{C}_6\text{H}_4\text{COCl}$. Obtained by heating di methyl aniline with COCl_2 at 50° in a sealed tube (Michler). Crystalline.

Nitrile $\text{NMe}_2\text{C}_6\text{H}_4\text{CN}$. From di methyl *p* phenylene diamine by Sandmeyer's reaction (Ahrens, *B* 20, 2958).

Anhydride of the methylo hydroxide

$\text{C}_6\text{H}_3\text{NO}_2$ i.e. $\text{C}_6\text{H}_3\text{<}\overset{\text{NMe}_2}{\text{CO}}\text{>O}$ [c 255°]. When *p* amido benzoic acid is mixed with MeI, KOH, and methyl alcohol, there is formed, even in the cold, di methyl *p* amido benzoic acid and the iodide $\text{NMe}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ which crystallises in short yellow plates [233°] (Michael & Wing, *Am* 7, 195). The corresponding anhydride crystallises from alcohol in colourless plates (containing aq), *v* sol water. It loses its water of crystallisation at 100°. The periodide forms long dark prisms [200°]. The platinumochloride ($\text{NMe}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$), PtCl_4 , forms large red prisms.

Tetra-methyl-di-amido-benzoic acid Di-methylo di-hydroxide

$(\text{HO NMe}_2)_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ [135]. The iodide $(\text{INMe}_2)_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ is formed when di amido-benzoic acid (1 pt) is mixed with MeI (6 pts), methyl alcohol (10 pts), and twice as much of a concentrated solution of KOH as is required to neutralise the acid. The mixture should stand for some time, being kept alkaline by further additions of potash. The alcohol is then distilled off, and the iodide ppd by HIAq (Griess, *B* 7, 59). This iodide crystallises from hot water in six sided tables or plates, *v* sol hot water. With moist Ag_2O it yields a caustic alkaline liquid which, on evaporation, leaves the hydroxide as a hygroscopic mass of soft white plates. It rapidly absorbs CO_2 , and ppt metallic oxides from their salts. The corresponding chloride $(\text{NMe}_2\text{Cl})_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ aq, obtained by neutralising the hydroxide by HCl, crystallises in small six sided plates, *v* sol water, *sl* sol hot alcohol. The periodide forms brownish yellow needles. The carbonate $\text{CO<O NMe}_2\text{>C}_6\text{H}_4\text{CO}_2\text{H}$ 3aq, obtained from the iodide and Ag_2CO_3 , crystallises from water in very small soluble plates, having an alkaline reaction. The platinumochloride $(\text{ClNMe}_2)_2\text{C}_6\text{H}_4\text{CO}_2\text{HPTCl}_4$ aq is a pp composed

of very small pale yellow plates, usually grouped in stars.

Derivative v CHLORO METHYL AMIDO BENZOIC ACID

DI-METHYL-*p*-AMIDO-BENZOIC ALDEHYDE, $\text{C}_6\text{H}_3\text{NO}$ i.e. $\text{NMe}_2\text{C}_6\text{H}_4\text{CHO}$ [78°]. Formed, together with CHCl_3 , by heating $\text{NMe}_2\text{C}_6\text{H}_4\text{CH(OH)Cl}$, with alcoholic KOH (Bossneck, *B* 18, 1520, 19, 366). With di methyl aniline and hydrochloric acid it forms $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{CH}$.

Oxim $\text{NMe}_2\text{C}_6\text{H}_4\text{CHNOH}$ [144°]. Yellowish brown plates (Knöfler & Bossneck, *B* 20, 3195).

Phenyl hydrazide $\text{NMe}_2\text{C}_6\text{H}_4\text{CHNHPh}$ [148°]. Needles (from alcohol).

DIMETHYL AMIDO BENZOPHENONE

$\text{C}_6\text{H}_5\text{CO C}_6\text{H}_4\text{NMe}_2$ *Benzodimethylaniline Benzoyl di methyl aniline* *Benzoyl phenyl di methyl amine* [90°]. Formed by heating the methylo iodide to 181°.

Formed also by heating malachite green $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C(OH)C}_6\text{H}_5$ with conc HClAq at 180°. Colourless plates (from alcohol). Insol water, *sl* sol cold alcohol, *v* e sol hot alcohol or ether. It is a feeble base, its solution in concentrated acids being ppd by water.

Methylo iodide $\text{C}_6\text{H}_5\text{CO C}_6\text{H}_4\text{NMe}_2\text{I}$. Large tables, *sl* sol cold water. Formed by heating *p* amido benzophenone with MeI at 100°. It decomposes at 181° (Doebner & Weiss, *B* 14, 1836, *A* 210, 270, 217, 257).

Di methyl-amido-benzophenone

$\text{C}_6\text{H}_5\text{CO C}_6\text{H}_4\text{NMe}_2$ [39°] (330°-340°). Obtained by heating benzoic acid with di methyl aniline and P_2O_5 at 185° (O Fischer, *A* 206, 88). Needles (from ligroin). Forms unstable salts. With nitrous acid it yields the oily nitroso derivative $\text{C}_6\text{H}_5\text{CO C}_6\text{H}_4(\text{NO})\text{NMe}_2$ (E Bischoff, *B* 22, 340).

Di-methyl-di-*p*-amido-benzophenone *Di-benzoyl derivative* $\text{C}_6\text{H}_3\text{N}_2\text{O}$ i.e. $(\text{NMeBz C}_6\text{H}_4)_2\text{CO}$ [102°]. Formed by heating tetra methyl di amido benzophenone with BzCl at 190° (Nathansohn & Muller, *B* 22, 1877). Small light brown plates, *sl* sol cold, *v* sol hot, alcohol, *sl* sol benzene, almost insol water and ether. Acids and alkalis at 100° do not saponify it.

Tri-methyl-di-amido-benzophenone

$\text{NHMe C}_6\text{H}_4\text{CO C}_6\text{H}_4\text{NMe}_2$ [156°]. Formed, together with di methyl aniline, by boiling penta methyl-tri-amido tri phenyl-carbinol with HClAq (Wichelhaus, *B* 19, 109). Nodular groups of needles (from alcohol).

Tetra-methyl-di-amido-benzophenone

$\text{NMe}_2\text{C}_6\text{H}_4\text{CO C}_6\text{H}_4\text{NMe}_2$ [172°] (above 360°) (Græbe, *B* 20, 3262).

Formation—1 By passing COCl_2 into di methyl aniline (Michler, *B* 9, 716, 1900).—2 By boiling hexa methyl tri amido tri phenol carbinol with HClAq (Wichelhaus, *B* 19, 109).—3 From CCl_4 , SO_2Cl and di methyl aniline (Michler & Moro, *B* 12, 1168).

Preparation—By boiling auramine with aqueous HCl till decoloured, and ppg with NH_3 .

Properties—White plates (from dilute alcohol), insol water, *m* sol alcohol, *v* e sol warm benzene, *v* *sl* sol ether.

Reactions—1 Heating with ZnCl_2 and

NH_4Cl at 160° produces auramine (Fehrmann, *B* 20, 2844) — 2 Boiling HNO_3 (S G 1 48) gives insoluble yellow crystals of tetra nitro di methyl-di nitramido benzophenone and tri nitro phenyl-methyl nitramine [127°], soluble in alcohol (Romburgh, *R T C* 6, 867) — 3 Excess of bromine added to a solution of the base in glacial acetic acid gives the tetra-bromo derivative ($\text{C}_6\text{H}_2\text{Br}_4\text{NMe}_2$), CO [172°] which crystallises in slender yellow needles from alcohol (Nathansohn a Muller, *B* 22, 1883) — 4 Heating with aniline hydrochloride yields phenyl auramine — 5 Combines with tri nitro benzene (2 mols) forming a compound which crystallises in long reddish violet needles [c 100°] With half the quantity of tri nitro benzene (1 mol) it forms small deep violet plates [123°] — 6 Combines with *m*-di-nitro benzene (2 mols) forming a red crystalline compound — 7 Nitrous acid in the cold forms the nitroso- derivative $\text{NMe}_2\text{C}_6\text{H}_4\text{CO C}_6\text{H}_4(\text{NOH})\text{NMe}_2$ [159°] crystal lising from alcohol in golden plates This substance is a weak base, its solution in HCl aq being pptd by water It gives Liebermann's reaction Stannous chloride reduces it to the original tetra methyl di amido benzophenone The nitroso derivative forms the following salts $\text{B}^+\text{H}_2\text{Cl}_2$ Obtained by passing HCl into a solution of the nitroso ketone in benzene — $\text{B}^+\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$ [152°] Orange needles (from alcohol) The nitroso ketone gives also a phenyl hydrazide $\text{C}_6\text{H}_5\text{NHNH C}_6\text{H}_4\text{N}_2\text{O}_2$ [148°] (E Bischoff, *B* 21, 2452, 22, 337) — 8 In presence of dehydrating agents, such as PCl_5 or AlCl_3 , it condenses with secondary and tertiary bases Thus with di methyl aniline it yields 'crystal violet' $\text{C}(\text{OH})(\text{C}_6\text{H}_5\text{NMe}_2)_3$.

Salts — $\text{B}^+\text{H Cl}_2$ small radially grouped prisms (from alcohol) Decomposed by water, with separation of the base (Fehrmann, *B* 20, 2844) — $\text{B}^+\text{H PtCl}_4$ yellow granules, insol water, v sl sol alcohol — Picrate $\text{B}^+\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$ [157°] Small, purple, radially grouped, prisms (from alcohol), insol cold, v sl sol hot, water, m sol alcohol

Di methyl di iodide $\text{B}^+\text{Me}_2\text{I}_2$ [105°] Light yellow plates (from alcohol), sl sol cold, v sol hot, water and alcohol Split up at 150° into MeI and the base (Nathansohn a Muller, *B* 22, 1876)

Di methylo-di-hydroxide $\text{B}^+\text{Me}_2(\text{OH})_2$ From the preceding and moist AgO Small yellow plates (from alcohol), quickly becoming dark and resinous (N a M)

Oxime $\text{HON C}(\text{C}_6\text{H}_5\text{NMe}_2)_2$ [233°], colourless crystals (Munohmeyer, *B* 19, 1852, 20, 1852)

Phenyl-hydrazide $\text{C}_6\text{H}_5\text{NHNH C}_6\text{H}_4\text{N}_2\text{O}_2$ ($\text{NMe}_2\text{C}_6\text{H}_4$), CN HPh [175°] Needles (from benzene-alcohol), m sol warm alcohol, v sol ether Coloured green by acid oxidising agents (Ziegler, *B* 20, 1111) Conc H_2SO_4 gives a red colouration

Imide ($\text{NMe}_2\text{C}_6\text{H}_4$), C NH Auramine base [136°] Formed by heating tetra-methyl-di-amido benzophenone with NH_4Cl and ZnCl_2 at 150° to 160° Formed also by treating a solution of tetra methyl-di-amido benzophenone in CS_2 with PCl_5 and subsequently adding ammonia (Caro a Kern) (cf AURAMINE in THORPE'S DICTIONARY OF APPLIED CHEMISTRY). Lemon-yellow

plates, insol water and ether, m sol alcohol Dilute HCl aq readily converts it, even in the cold, into tetra methyl di amido benzophenone

Reactions — 1 Sodium amalgam reduces it (in alcoholic solution) to leucauramine ($\text{C}_6\text{H}_5\text{NMe}_2$), CH NH_2 [185°] This substance forms colourless crystals which when treated with HOAc yield an intense blue solution (Græbe, *B* 20, 3265) — 2 H_2S in alcoholic solution at 60° forms tetra methyl di amido thio benzophenone [164°] — 3 CS_2 also forms ($\text{NMe}_2\text{C}_6\text{H}_4$), CS together with thiocyanic acid (Fehrmann, *B* 20, 2847)

Salts — B^+HCl aq Auramine Yellow six sided tables (from water at 70°) After expulsion of the water it melts (G) or decomposes (F) at 267° M sol cold water, m sol alcohol Boiling water converts it into tetra methyl di-amido benzophenone Dyes wool and silk greenish yellow Cotton prepared with tannin is also dyed yellow by auramine — $\text{B}^+\text{H}_2\text{PtCl}_4$ granules, insol water, sl sol alcohol — B^+HI [268°] Minute columns — B^+HSCy aq [200° – 210°] — $\text{B}^+\text{H.C}_2\text{O}_4$ [194°] Orange needles, sl sol water, m sol warm alcohol — $\text{B}^+\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$ [230° – 236°] Plates, insol cold, v sl sol hot, water, m sol hot alcohol

Phenyl imide ($\text{NMe}_2\text{C}_6\text{H}_4$), C NPh Formed by heating the hydrochloride of the imide (auramine) with aniline at 180° (F). Small greyish-yellow radially grouped needles (from alcohol), decomposing at 80° Insol water and ether — B^+HCl reddish crystalline mass, sol water and alcohol Its aqueous solution gradually decomposes, yielding aniline and tetra methyl di-amido benzophenone — $\text{B}^+\text{H}_2\text{PtCl}_4$ — $\text{B}^+\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$

p Tolyli imide ($\text{NMe}_2\text{C}_6\text{H}_4$), $\text{C NC}_6\text{H}_4\text{Me}$ Resembles the phenyl imide — $\text{B}^+\text{H.PtCl}_4$

Ethylene-di-amide $\text{C}_6\text{H}_5\text{N}_2\text{Me}$

($\text{NMe}_2\text{C}_6\text{H}_4$), $\text{C} \begin{array}{c} \text{NH CH}_2 \\ | \\ \text{NH CH}_2 \end{array} \text{C}$ Formed by heating auramine (hydrochloride) with ethylene diamine at 100° – 110° (Fehrmann, *B* 20, 2855) Yellowish plates (from alcohol), insol water, m sol warm alcohol On treatment with HOAc or dilute HCl aq it decomposes into ethylene diamine and ($\text{NMe}_2\text{C}_6\text{H}_4$), CO In alcoholic solution it is decomposed by H_2S into ethylene diamine and ($\text{NMe}_2\text{C}_6\text{H}_4$), CS — $\text{B}^+\text{H}_2\text{PtCl}_4$ yellow needles — $\text{B}^+\text{H}_2\text{PtCl}_4$ amorphous flakes, insol water and ether, v sol warm alcohol — $\text{B}^+\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$ flakes, v sl sol water, v sol alcohol.

Tolylene di amide

($\text{NMe}_2\text{C}_6\text{H}_4$), $\text{C} \begin{array}{c} \text{NH} \\ | \\ \text{NH} \end{array} \text{C}_6\text{H}_4\text{Me}$ Formed by heating the hydrochloride of the imide (auramine) with (1, 2, 4) tolylene diamine at 160° , and treating the product with ammonia Small brown scales In dilute acetic acid solution it dyes cotton, mordanted with tannin, reddish-brown Dilute HCl aq regenerates the original ketone — $\text{B}^+\text{H}_2\text{PtCl}_4$ — $\text{B}^+\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$

Tetra-methyl-tri-amido-benzophenone

$\text{C}_6\text{H}_5\text{N}_3\text{O}_2$ + $\text{NMe}_2\text{C}_6\text{H}_4\text{CO C}_6\text{H}_4(\text{NH}_2)(\text{NMe}_2)$ [82°] Obtained by reducing nitro-tetra methyl-di amido benzophenone (Nathansohn a Muller, *B* 22, 1884) Amorphous yellow powder, v sol hot, sl sol cold, alcohol and benzene, insol ether — $\text{B}^+\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$ minute plates, v sol

hot alcohol, insoluble in benzene and ether — $B'H_3PtCl_6$, light red crystalline pp, v sol warm alcohol, sl sol benzene, insol water and ether

METHYL- α -AMIDO- n -BUTYRIC ACID

$C_6H_{11}NO_2$, *i.e.* $CH_3CH_2CH(NHMe)CO_2H$. Formed by heating α -bromo-butyric acid with a concentrated solution of methylamine in sealed tubes at 100° . The product is boiled with baryta to expel NH_4Me , the Ba exactly ppd by H_2SO_4 , and the HBr by Ag_2CO_3 (Duvillier, *A Ch* [5] 20, 188, *C R* 83, 425). Glistening leaflets (from alcohol), subliming above 120° without fusion. V sol water, m sol hot alcohol, insol ether. Has a sweet taste. Feebly acid in reaction. By the prolonged action (several months) of cyanamide (1 mol) in concentrated and slightly ammoniacal solution it is converted into butyrocresatinine $CH_3CH_2CH<\frac{CO\ NH}{N(CH_3)}>C\ NH$

which crystallises from alcohol in slender silky needles composed of small rectangular plates (Duvillier, *C R* 95, 456, *Bl* [2] 39, 539).

Salts — $HA'HCl$ [150°]. Badly defined crystals, sol alcohol, insol ether. Gives off HCl on fusion — $H_2A'H_2PtCl_6$, orange-red crystals, v sol water and alcohol, insol ether — $H_2A'H_2PtCl_6$, 5 aq. Formed at 0° — $HA'HAuCl_4$, aq. transparent yellow prisms, sol water, alcohol, and ether — The nitrate and sulphate crystallise with difficulty in long needles — $CuA', 2aq$, light-blue prisms, sol alcohol.

Di methyl α -amido-butyric acid *Anhydride of the methylo-hydroxide* $C_6H_{11}NO_2$, CH_3CH_2CH-CO

i.e. $(CH_3)_2N-O$ **Tri-methyl- α -amido-butyro-betaïne** Prepared by the action of bromo butyric ether on an excess of tri methylamine in alcoholic solution (Duvillier, *C R* 104, 1520). Large transparent crystals, containing aq, which they lose at 120° , becoming opaque, v sol. water and alcohol, insol ether. Has a bitter taste — $B'HCl$. Uncrystallisable — $B'H_3PtCl_6$, orange prisms, sl sol alcohol. The aurochloride forms yellowish-white crystals.

METHYL AMIDO-CAPROIC ACID *v* **METHYL-AMIDO HEXOIC ACID**

METHYL-AMIDO-CHLORO- *v* **CHLORO-METHYL-AMIDO**

METHYL-AMIDO-CYANURIC ACID *v* **CYANIC ACID**.

METHYL-AMIDO-ETHANE SULPHONIC ACID $C_6H_{11}NSO_3$, *i.e.* $CH_3NHCH_2CH_2SO_3H$ *Methyl-taurine* [242].

Formation — From methyl-ethylene- ψ thio-urea and bromine-water (Gabriel, *B* 22, 1148).

Preparation — Silver chloro-ethane sulphonate is heated with 8 times its weight of a solution of methylamine, saturated at 0° , for 5 hours at 120° . The product is boiled with baryta to expel excess of methylamine, freed from excess of baryta by H_2SO_4 , and evaporated to crystallisation. The crystals are washed with alcohol and recrystallised from water. The yield is 25 p.c. (E. Dittrich, *J pr* [2] 18, 66).

Properties — Transparent triclinic crystals. Sol water, insol alcohol and ether. Its aqueous solution is acid to litmus. Crystallises un-

altered from strong HCl. Does not form salts with acids and alkalis.

Reactions — 1 N_2O_5 forms isethionic acid, $(HO)CH_2CH_2SO_3H$ — 2 With cyanamide it combines to methyl taurocyamine or methyl guanido-ethane sulphonic acid.

Di methyl amido ethane sulphonic acid $NMe_2CH_2CH_2SO_3H$. Formed by heating di methylamine β chloro ethane sulphonate (20 g) with aqueous (53 p.c.) dimethylamine (5 g) at 160° for 10 hours (James, *J pr* [2] 31, 416, *C J* 47, 370). Large tabls (from water), v sol water, insol ether. Decomposes at 270° — 280° without fusion. Does not combine with HCl.

Anhydride of the methylo hydroxide $<\frac{CH_2NMe_2}{CH_2SO_3}>O$. Formed by heating β chloro-ethane sulphonic acid with aqueous tri methylamine. Slender prisms (from water), v sol water, insol alcohol and ether. Neutral in reaction. Tastes sweet. Not decomposed at 300° . Not acted upon by cyanamide. Baryta gives NMe_2 and isethionic acid (James, *C J* 49, 489).

DI-METHYL-AMIDO-ETHYL ALCOHOL *v* **DI-METHYL-OXYETHYL AMINE**

DI-METHYL AMIDO ETHYL BENZENE *v*

DI-METHYL AMIDO PHENYL ETHANE

METHYL-AMIDO-ETHYL KETONE

$CH_3COCH(NH_2)CH_3$. Perhaps formed by reducing methyl nitroso ethyl ketone, but if so it quickly changes to *s*-tetra methyl pyrazine.

METHYL-AMIDO-FORMIC ACID *v* **METHYL-CARBAMIC ACID**

METHYL- α -AMIDO n HEXOIC ACID

$C_6H_{11}NO_2$, *i.e.* $CH_3CH_2CH_2CH_2CH(NHMe)CO_2H$ *Methyl-amido caproic acid* S 102 at 11° . Formed by heating α -bromo-hexoic acid (1 mol) with aqueous methylamine (2 or 3 mols) at 100° for several hours (Duvillier, *C R* 90, 822, *A Ch* [5] 29, 165). Silky needles (from water) or pearly plates (from alcohol). Sl sol cold alcohol, insol ether. Neutral in reaction. Volatilises above 100° . Does not reduce silver or mercurous nitrate. Gives with ferric chloride an intense red colouration and a yellowish brown pp. An equivalent quantity of cyanamide in cold concentrated solution containing a few drops of NH_3 forms in a few weeks crystals of 'hexoic

creatinine' $C_6H_7CH<\frac{NMe\ C\ NH}{CO\ NH}>$ Sl sol.

cold water, v sol alcohol (Duvillier, *C R* 96, 1583, *Bl* [2] 40, 307) — $HA'HCl$ transparent plates, v sol water and alcohol, insol ether — $H_2A'H_2PtCl_6$, orange crystals, v sol water, v sol alcohol, v sl sol ether — The aurochloride forms golden needles, the sulphate forms very indistinct crystals — $CuA', 2aq$, blue scales, S 1.

Di methyl amido-hexoic acid *Methylo-hydroxide* $HO\ NMe_2\ C_6H_{11}\ CO_2H$. Formed by heating leucine (1 mol) derived from casein with aqueous KOH (3 mols) and MeI (3 mols). The resulting $INMe_2\ C_6H_{11}\ CO_2K$, which crystallises from alcohol in needles, being decomposed by moist Ag_2O (Körner a Menozzi, *G* 13, 359). Strongly alkaline. Decomposes at 120° — 130° into trimethylamine, an acid, $C_6H_{11}O_2$, and oxy-hexoic acid. Forms the platinochloride

(CINMe_2 , C_6H_5 , CO_2H). PtCl_2 , aq., aurochloride $\text{Cl}_2\text{AuNMe}_2$, C_6H_5 , CO_2H [163°], and periodide. The periodide forms lustrous green crystals, decomposed by H_2S , yielding INMe_2 , C_6H_5 , CO_2H [191°], crystallising in small prisms

DI-METHYL-AMIDO-HYDROQUINONE

$\text{C}_6\text{H}_3(\text{NMe}_2)(\text{OH})_2$ [2 4 1] *Di methyl derivative* $\text{C}_6\text{H}_3(\text{NMe}_2)(\text{OMe})$

Methylo iodide B'MeI [202°] Formed by heating the di methyl derivative of amido hydroquinone with methyl iodide (Bässler, *B* 17, 2122) White needles, v sol water, sl sol absolute alcohol, nearly insol benzene, chloro form, and ligroine

Methylo hydroxide B'MeOH soluble needles

Methylo chloride B'MeCl white easily soluble needles [172°] — (B'MeCl), PtCl_2 , yellow crystalline pp

TRI METHYL-AMIDO IMIDO IMIDO DI-PHENYL SULPHIDE

Methylo chloride $\text{C}_6\text{H}_3\text{N}_3\text{S}_2\text{Cl}_2$ $\text{N} \begin{array}{c} \text{C}_6\text{H}_3(\text{NMe}) \\ \text{C}_6\text{H}_3 \end{array} \text{S} \text{Methylene}$
 NMe_2Cl

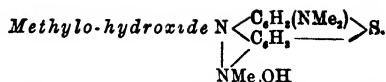

blue Chloride of tetra methyl thionine

Formation — 1 By the action of H_2S on an acid solution of nitroso di methyl aniline and oxidation of the resulting leuco methylene blue. In this reaction di methyl *p* phenylene diamine is an intermediate product (Caro, *E P* 1877, 3751, Koch, *B* 12, 593, Bernthsen, *A* 230, 137) — 2 By dissolving nitroso di methyl aniline in H_2SO_4 (S G 14), treating with sulphide of zinc, and oxidising the resulting leuco methylene blue (Oehler, *G P* 1882, 24,125, Muhliauser, *D P J* 262, 371) — 3 By oxidation of di methyl *p* phenylene diamine in presence of $\text{Na}_2\text{S}_2\text{O}_8$, and further oxidation of the resulting $\text{C}_6\text{H}_3(\text{NMe}_2)(\text{NH}_2)\text{S SO}_3\text{H}$ by chromic acid (Bernthsen) — 4 By reducing the compound $\text{C}_6\text{H}_3(\text{NMe}_2)(\text{NH}_2)\text{S SO}_3\text{H}$ to $\text{C}_6\text{H}_3(\text{NMe}_2)(\text{NH}_2)\text{SH}$ and oxidising a mixture of this mecaptan with di methyl aniline with HCl and $\text{K}_2\text{Cr}_2\text{O}_7$, the resulting 'soluble green' $\text{C}_6\text{H}_3\text{N}_3\text{S}$ or $\text{N} \begin{array}{c} \text{C}_6\text{H}_3(\text{NMe}_2) \\ \text{C}_6\text{H}_3 \end{array} \text{S}$ slowly changing in aqueous

solution to methylene blue (Bernthsen, *A* 251, 10)

Properties — Minute dark blue laminae (containing 3aq), v sol water and alcohol. Dyes mordanted cotton blue. Its aqueous solution is blue and not affected by HCl or ammonia. NaOH gives a violet colour and, when added in large quantity, a dirty violet pp. Conc H_2SO_4 gives a yellowish green solution, becoming blue on dilution. The aqueous solution is decolourised by H_2S or $\text{Na}_2\text{S}_2\text{O}_3$, the colour is restored even by feeble oxidising agents. Sodium hyposulphite $\text{Na}_2\text{S}_2\text{O}_4$ reduces it to the leuco base. Fuming HCl at 260° decomposes it, giving off H_2S . Boiling dilute HNO_3 oxidises it, forming H_2SO_4 . Boiling aqueous KOH forms 'thionol', the anhydride of di-oxo-imido-di phenyl sulphide $\text{N} \begin{array}{c} \text{C}_6\text{H}_3(\text{OH}) \\ \text{C}_6\text{H}_3 \end{array} \text{S}$

Salt — ($\text{C}_6\text{H}_3\text{N}_3\text{S}_2\text{Cl}_2$), ZnCl_2 , aq.

Formed by treating methylene blue with moist Ag_2O . Amorphous, dark blue mass, v e sol. water and alcohol, insol ether

Methylo iodide $\text{C}_6\text{H}_3\text{N}_3\text{SI}$ bronzy needles (from hot water). The di chloro derivative of this iodide $\text{C}_6\text{H}_3\text{Cl}_2\text{N}_3\text{SI}$ is formed by successive treatment of di chloro di methyl *p* phenylene diamine $\text{C}_6\text{H}_3\text{Cl}_2(\text{NMe}_2)(\text{NH}_2)$ with H_2S , FeCl_3 , and KI (Mohlau, *B* 19, 2012)

TRI METHYL-AMIDO IMIDO IMIDO DI-PHENYL-SULPHONE

Methylo-iodide $\text{C}_6\text{H}_3\text{N}_3\text{SO}_2\text{I}$ $\text{N} \begin{array}{c} \text{C}_6\text{H}_3(\text{NMe}_2) \\ \text{C}_6\text{H}_3 \end{array} \text{SO}_2 \text{Methyl-}$
 NMe_2I

ene azure Formed, together with methylene violet, by boiling methylene blue with Ag_2O and a large quantity of water (Bernthsen, *A* 230, 175). Slender needles with green lustre, sol water, forming a violet solution from which it is pptd by KI . Alkalis destroy the colour of the solution. The corresponding $\text{C}_6\text{H}_3\text{N}_3\text{SO}_2\text{Cl}$ crystallises in needles, v e sol water. It dyes silk like methylene blue

TETRA METHYL-DI AMIDO-IMIDO DI-PHENYL METHANE v Imide of Tetra-METHYL-DI AMIDO-BENZOPHENONE

METHYL-DI-AMIDO IMIDO DI-PHENYL SULPHIDE $\text{C}_6\text{H}_3\text{N}_3\text{S}$ $\text{NMe} \begin{array}{c} \text{C}_6\text{H}_3(\text{NH}_2) \\ \text{C}_6\text{H}_3 \end{array} \text{S}$

Methyl di amido thio diphenylamine Formed by reduction of di nitro methyl imido-di phenyl sulphide with tin and HCl (Bernthsen, *A* 230, 130). Insol water, sol ether. The dilute solution of its hydrochloride is coloured blue by FeCl_3 — $\text{B'H}_4\text{Cl}_2$. Needles, v sol water, almost insol HCl aq

Tetra methyl-di-amido-imido-di phenyl sulphide $\text{C}_6\text{H}_3\text{N}_3\text{S}$ $\text{NH} \begin{array}{c} \text{C}_6\text{H}_3(\text{NMe}_2) \\ \text{C}_6\text{H}_3 \end{array} \text{S}$

Leuco methylene blue Formed by treating methylene blue with sodium hyposulphite $\text{Na}_2\text{S}_2\text{O}_4$ (Bernthsen, *A* 230, 147). Needles (from alcohol), sl sol water, m sol cold alcohol. Gives an acetyl derivative, v sol alcohol, ether and benzene. With MeI it forms $\text{NMe} \begin{array}{c} \text{C}_6\text{H}_3(\text{NMe}_2\text{I}) \\ \text{C}_6\text{H}_3 \end{array} \text{S}$ crystallising in plates, v sl sol water and alcohol, insol ether. Oxidised by air to methylene blue — $\text{B'H}_4\text{ZnCl}_2$, prisms

Di-methyl amido imido phenyl disulphide *Methylo chloride* $\text{C}_6\text{H}_3\text{N}_3\text{S}_2\text{Cl}_2$ S

$\text{NMe}_2\text{Cl} \begin{array}{c} \text{C}_6\text{H}_3 \\ \text{N-S} \end{array} \text{S} \text{Methylene red}$ A by product in the manufacture of methylene-blue from di methyl *p* phenylene diamine and H_2S followed by FeCl_3 (Bernthsen, *A* 230, 165, 251, 22, Koch, *B* 12, 594). Small green glittering prisms (from alcohol), v e. sol. water, insol ether. Its aqueous and alcoholic solutions are purple. Not affected by HCl . Alkalis decompose it — Zinc salt ($\text{C}_6\text{H}_3\text{N}_3\text{S}_2\text{Cl}_2$), ZnCl_2 , aq

DI-METHYL-AMIDO-JUGLONE v. JUGLONE.

METHYL-AMIDO-MESITYLENE v. METHYL-MESIDINE.

METHYL AMIDO METHYL-BENZENES v.
METHYL-PHENYL METHYL AMINES

DI-METHYL-AMIDO-METHYL-PHEN.

AZINE $C_6H_5(NMe_2) \begin{smallmatrix} \diagup N \diagdown \\ | \\ C_6H_5Me \end{smallmatrix}$ Formed by

elimination of the NH group from 'tolylene red' by means of nitrous acid and alcohol (Bernthsen & Schweitzer, *B* 19, 2605) Red greenish glistering needles or flat prisms Has basic properties Dissolves in dilute acids with a violet colour, in conc H_2SO_4 with a reddish brown, which on dilution first becomes green, then blue, and finally violet Soluble in ether with a yellowish-red colour and yellow fluorescence Sublimable

Di methyl di-amido methyl phenazine

$C_{13}H_{16}N_4$ v e $C_6H_5(NMe) \begin{smallmatrix} \diagup N \diagdown \\ | \\ C_6H_5Me(NH_2) \end{smallmatrix}$

Tolylene red Formed by oxidation of nitroso-amido dimethyl aniline together with tolylene *m* diamine The leuco base has the formula $C_6H_5(NMe_2) \begin{smallmatrix} \diagup NH \diagdown \\ | \\ C_6H_5Me(NH) \end{smallmatrix}$ (Bernthsen & Schweitzer, *B* 19, 2604)

DI METHYL AMIDO METHYL-QUINOLINE TETRAHYDRIDE *Di-methylo di-iodide* $C_8H_8Me_2N NMe_2Me_2I_2$ [171°] Formed by heating (*Py* 1) amido quinoline tetrahydride with methyl alcohol and MeI (Ziegler, *B* 21, 862) Crystals

METHYL-AMIDO METHYL-THIAZOLE

$C_5H_5N_2S$ v e $\begin{smallmatrix} S C(NHMe) \\ | \\ CH=CMe \end{smallmatrix} \begin{smallmatrix} \diagup N \diagdown \end{smallmatrix}$ *Methyl thiazyl-*

amine [42°] Formed by the action of chloroacetone on methyl thio urea (Traumann, *A* 249, 44) Crystalline but extremely hygroscopic, *m* sol ether Strongly alkaline in reaction When heated with $HClAq$ in a sealed tube it yields methylamine Br completely decomposes it

Salts— B^+H^- small white needles, melts, when anhydrous, at 136° (*T*)—Platinochloride orange yellow plates [167°]

Acetyl derivative $C_5H_5AcN_2S$. [110°] White needles

Methyl-amido-methyl thiazole

$S C(NH) \begin{smallmatrix} \diagup NMe \diagdown \\ | \\ CH CMe \end{smallmatrix}$ *Imido di methyl thiazole*

[47.5°] Formed from chloro acetone by treatment with ammonium sulpho cyanide (Tehernia & Norton, *B* 16, 345) and heating with MeI the resulting amido methyl thiazole (so-called propinine sulphocyanide) (Hantzsch & Weber, *B* 20, 3122, 3336) Crystalline, but very hygroscopic Strongly alkaline When heated with $HClAq$ in sealed tubes it yields ammonia Conc $KOHAq$ has no action

Salts— B^+H^- Tables [164°]—Platinochloride orange tables [193°]

Acetyl derivative $C_5H_5AcN_2S$ [113°] White needles (containing 6 aq)

Di-methyl-amido-methyl-thiazole $C_5H_{10}N_2S$ $S \cdot C(NMe) \begin{smallmatrix} \diagup NMe \diagdown \end{smallmatrix}$

v e $\begin{smallmatrix} CH=CMe \end{smallmatrix} \begin{smallmatrix} \diagup NMe \diagdown \end{smallmatrix}$ *Methyl imido dimethyl-thiazole* [96°] Formed by adding conc $KOHAq$ to its hydro-iodide (Hantzsch & Weber, *B* 20, 3123) White needles, sol alcohol, water, and

ether Bromine reacts with formation of $C_5MeBr(NMe_2)SN$ [114°]

Salts— B^+H^- [54°] From MeI and $C_5MeH(NHMe)SN$ Melts at 155° when anhydrous

Methylo-iodide B^+MeI [85°] White needles, v e sol water and alcohol

DI-METHYL-AMIDO-NAPHTHOIC ACID $C_{10}H_7(NMe_2)(CO_2H)$ [14] [165°] Formed by heating di methyl (a) naphthylamine with $COCl_2$ at 70° for 4 hours (Friedlander, *B* 21, 3126) Needles (from dilute alcohol), sol dilute acids and alkalis When acted upon by diazo compounds the azo-group displaces the COH —(HA^+) H^+PtCl_6 yellow needles

DI METHYL AMIDO-NAPHTHO-PHEN

AZINE $C_{10}H_7 \begin{smallmatrix} \diagup N \diagdown \\ | \\ C_6H_5 NMe_2 \end{smallmatrix}$ *Di methyl*

naphth eurhodine [205°] Formed from nitroso di methyl aniline hydrochloride, (β) naphthylamine, and $AcHO$ (Witt, *B* 21, 720) Rhombic tables (from toluene or xylene), red by transmitted, and red or green, according to the faces, by reflected light, sol alcohol, ether and benzene, forming yellow solutions with yellow fluorescence Is volatile with slight decomposition, and sublimes readily in woolly flocks The violet red solution in conc H_2SO_4 becomes successively black, green, grey, and blue violet on dilution The salts crystallise readily, have a bronzy lustre, and are dissociated by water $AcHO$ dissolves it with red violet colour Conc HNO_3 with violet, soon becoming bright yellow and depositing the nitro compound

METHYL-AMIDO NAPHTHOQUINONE

$C_{11}H_9NO_2$ v e $C_{11}H_9O_2(NHMe)$ [232°] Formed by adding a solution of methylamine acetate to an alcoholic solution of (a) naphthoquinone, evaporating nearly to dryness, adding water, and crystallising the pp from alcohol (Plimpton, *C J* 37, 639) Glittering red needles, v sol alcohol Aqueous SO_2 at 150° forms an unstable colourless reduction product

Di-methyl-amido-naphthoquinone

$C_{10}H_7O_2(NMe_2)$ [118°] From (a) naphthoquinone and di methyl amine in alcoholic solution (Plimpton) Red needles

DI-METHYL AMIDO-NAPHTHYLAMINE v

NAPHTHYLENE DI METHYL DIAMINE

TETRA-METHYL-DI-AMIDO-DI NAPHTHYL PHENYL-METHANE

$Ph CH(C_6H_4NMe_2)_2$ [189°] Formed by the action of benzoic aldehyde on di methyl (a) naphthylamine in presence of $ZnCl_2$ (Friedlander, *B* 21, 3128) Colourless crystals, v sol $HOAc$, benzene, CS_2 , and dilute mineral acids, sl sol alcohol, ether Does not yield a colour on oxidation

Hexa methyl tri amido-di-naphthyl phenyl methane $HC(C_6H_4NMe_2)_3C_6H_4NMe_2$ [179°] Formed by condensing di-methyl *p* amido benzoic aldehyde with di methyl (a) naphthylamine in presence of $ZnCl_2$ (Friedlander, *B* 21, 3129) White needles Does not yield a colour on oxidation

METHYL-AMIDO-NITRO- compounds v **NI TRO-METHYL-AMIDO-** compounds

METHYL-AMIDO-OXY- compounds v **OXY METHYL-AMIDO-** compounds

AMIDO PIPITZARIC ACID

METHYL o AMIDO-PHENOL *Methyl derivative* C_6H_4NO *is* $C_6H_4(NHMe)(OMe)$ [1 2]*Methyl anisidine* (219°) Formed by mixing the methyl derivative of *o* amido phenol with MeI at 0° (Mühlhauser, A 207, 247) Oil — B'H PtCl₅ short yellow prisms, *m* sol water**Methyl-p amido phenol** *Ethyl derivative* C_6H_4NO *is* $C_6H_4(NHMe)(OEt)$ [1 4] (251°) Formed by heating the ethyl derivative of *p* oxy phenyl amido acetic acid at 260° (Bischoff & Nastvogel, B 22, 1789) Sl sol water, *v* sol alcohol and ether — B'HCl needles**Di methyl o amido phenol** C_6H_3NO *is* $C_6H_3(NMe_2)(OH)$ [1 2] [45°] Obtained, together with MeCl, by the dry distillation of the methyl chloride (Griess, B 13, 248) Small white prisms, *v* sl sol hot water, *v* sol alcohol, ether, HOAc, and aqueous KOH FeCl₃ gives a reddish violet colour Its hydrochloride is gummy**Methylo hydroxide** $C_6H_4(NMe_2OH)(OH)$ or $C_6H_4\begin{smallmatrix} O \\ | \\ NMe_2 \end{smallmatrix}$ aq Prepared by the action ofMeI and KOH on a solution of *o* amido phenol in methyl alcohol (Griess, B 13, 246) Prisms,which become $C_6H_4\begin{smallmatrix} O \\ | \\ NMe \end{smallmatrix}$ at 105° *V* solwater and alcohol, *insol* ether Has an intensely bitter taste On distillation it is converted into $C_6H_4(NMe)(OMe)$ With acids it forms the following salts — $C_6H_4(NMe_2I)(OH)$ aq white soluble prisms Its solution, neutralised by ammonia, deposits sparingly soluble needles orprisms of $C_6H_4(NMe_2I)(OH)C_6H_4\begin{smallmatrix} O \\ | \\ NMe_2 \end{smallmatrix}$ — $C_6H_4(NMe_2Cl)(OH)$ 2aq long soluble prisms — $C_6H_4(NMe_2Cl)(OH)$ PtCl₅ yellowish red needles, sl sol cold water — The periodide forms brown insoluble leaflets — The nitroprusside (C_6H_3NO), H FeCy₃NO forms crystals, sl sol cold water**Methyl derivative** C_6H_3NO *is* $C_6H_3(NMe)(OMe)$ [1 2] (211°) SG 2³ 1 016 Formed by an isomeric change by distilling $C_6H_4\begin{smallmatrix} O \\ | \\ NMe \end{smallmatrix}$ (Griess, B 13, 248) Formed alsofrom MeI and the methyl derivative of *o* amido-phenol (Mühlhauser, A 207, 248) Colourless liquid, with burning taste — B'H₂PtCl₅ sparingly soluble golden yellow prisms**Methylo iodide** of the *methyl derivative* $C_6H_3(NMe_2I)(OMe)$ From the preceding and MeI Long white needles (G) or tables (M), sol hot water and hot alcohol With moist Ag₂O it yields a strongly alkaline hydroxide It also yields a platinumchloride ($C_6H_3(NMe_2Cl)(OMe)$ PtCl₅), which crystallises in sparingly soluble yellow plates or tables**Di-methyl-m-amido-phenol** $C_6H_4(OH)NMe_2$ Prepared by fusing di methyl amido benzene *m* sulphonic acid with KOH Also by heating resorcin with di methyl amine under pressure**Ethyl ether** $C_6H_4(OEt)(NMe_2)$ [1 3] (247°) Obtained by boiling a solution of *m* amido-phenol and methyl iodide and slowly runningin the calculated quantity of potash The base is distilled over with steam (P Wagner, J pr [2] 32, 77, Baur & Stadel, B 16, 32) Converted by HCl and amyl nitrite into the nitroso compound $C_6H_3(NO)(OEt)(NMe)$ **Di-methyl-p-amido-phenol** *Methylohydroxide* The anhydride $C_6H_4\begin{smallmatrix} O \\ | \\ NMe_2 \end{smallmatrix}$ *is* formed by the action of MeI and conc KOHAq upon *p* amido phenol in the cold (Griess, B 13, 250) Prisms or plates Changes on distillation into the isomeric $C_6H_4(NMe_2)(OMe)$ [48°]**Methyl derivative** $C_6H_3(NMe)(OMe)$ [1 4] [49°] Formed as above (Griess, B 13, 249) Prisms or plates (from alcohol)**Methylo iodide** $C_6H_3(NMe_2I)(OMe)$ Formed by the action of MeI on either the methyl derivative or the methylo hydroxide Tables or plates With moist Ag₂O it yields the methylo hydroxide as a strongly alkaline mass. The platinumchloride ($C_6H_3(NMe_2Cl)(OMe)$ PtCl₅), forms small yellow prisms, sl sol water**Di-methyl-di-amido-phenol** *Anhydride* of the *methylo hydroxide* $C_6H_3N_2O$ *is* $C_6H_3(NH_2)\begin{smallmatrix} O \\ | \\ NMe_2 \end{smallmatrix}$ [4 1] [4 2] Prepared by reductionof the methylo hydroxide of nitro di methyl amido phenol with tin and HCl (Griess, B 13, 648) — B'H₂Cl₂ 4aq very soluble white plates — B'H PtCl₅ 2aq small prisms, sl sol water**TETRA-METHYL-DI-p-AMIDO-DIPHENYL** $NMe_2.C_6H_4.C_6H_4.NMe_2$ *Tetra methyl benzidine* [195°] (above 360°)**Formation** — 1 By heating di methyl aniline (1 pt) with H₂SO₄ (4 pts) at 200° Formed also in small quantity by oxidising di methyl aniline by boiling with PbO₂ and dilute H₂SO₄ (Miehler & Pattinson, B 14, 2161, 17, 115) — 2 By heating di methyl aniline with AlCl₃ in presence of air (Gnaud, Bl [3] 1, 692) — 3 By methylation of benzidine**Properties** — Colourless needles, sol hot, sl sol cold, alcohol Not volatile with steam Gives a green colouration with FeCl₃ or CrO₃ — B'H₂Cl, sparingly soluble needles — B'H₂Br, needles — B'H₂L white needles — B'H PtCl₅**Methylo iodide** B'MeI [263°] Needles, sl sol water and alcohol Loses MeI when distilled with soda lime**Methylo chloride** B'MeCl [228°] Crystals, very soluble in water and alcohol — B'MeClHPtCl₅ yellow pp**Tetra methyl op di amido diphenyl** (2 1) $NMe_2.C_6H_3.C_6H_3.NMe_2$ [1 4] *Tetra methyl diphenylamine* [52°] (333°-345°) Formed by heating diphenylamine hydrochloride with MeOH in sealed tubes at 180° (Reuland, B 22, 3015) Prisms Gives with platinum chloride an unstable pp Chloranil produces a blue colouration — B'C₆H₃(NO₂)₂OH [200°] Red needles**Methylo iodide** B'MeI [184°] Needles, *v* sol water, alcohol, and ether**Di methylo di-iodide** B'Me₂I₂ [196°] Crystalline, *v* sol water and alcohol**Tetra-methyl tetra-amido diphenyl** $NMe_2.C_6H_3(NH_2).C_6H_3(NH_2).NMe_2$ *Tetra-methyl benzidine* [168°] Prepared by reduction of di-

nitro tetra methyl diphenyl (Michler & Pattinson, *B* 14, 2165, 17, 118) White silvery plates, ν sol hot alcohol, sl sol cold alcohol, insol water. FeCl_3 gives a violet colouration. $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 produce a brownish red colour— $\text{B}^*\text{H}_2\text{Cl}_2$ (dried at 110°) sparingly soluble colourless needles— $\text{B}^*\text{H}_2\text{I}_2$ sparingly soluble needles— $\text{B}^*\text{H}_2\text{PtCl}_6$ yellow pp

Methyl α amido phenyl acetic acid $\text{C}_6\text{H}_4\text{NH}_2\text{CO}_2\text{H}$ $\text{C}_6\text{H}_4\text{CH}(\text{NHMe})\text{CO}_2\text{H}$ Formed from the nitrile of mandelic acid $\text{C}_6\text{H}_4\text{CH}(\text{OH})\text{CN}$ by digesting with alcoholic NH_4Me at 70° , and decomposing the resulting nitrile with HCl (Tiemann & Piest, *B* 14, 1982) Slender needles (from hot water) Sublimes at 274° Sl sol cold water, insol alcohol and ether

Amide $\text{C}_6\text{H}_4\text{CH}(\text{NHMe})\text{CONH}_2$ [155°] Slender needles— B^*HCl Needles, sol alcohol, insol ether

DI-METHYL-AMIDO-PHENYL- ω -AMIDO-CRESOL *Methyl derivative*

[4 1] $\text{NMe}_2\text{C}_6\text{H}_4\text{NHCH}_2\text{C}_6\text{H}_4\text{OMe}$ [1 4] [104°] Formed by reducing $\text{NMe}_2\text{C}_6\text{H}_4\text{NCH}_2\text{C}_6\text{H}_4\text{OMe}$ with sodium (Steinhart, *A* 241, 343) Light green plates, ν sol acids, forming red solutions. Its alcoholic solution decomposes rapidly

DI-METHYL-AMIDO-DI-PHENYL-AMINE $\text{Me}_2\text{NCH}_2\text{C}_6\text{H}_4\text{NHPH}$ [130°] One of the products formed by the action of phenyl hydrazine on nitroso dimethylamine in an alcoholic solution (O Fischer, *B* 21, 2612) White needles (from petroleum-ether), ν sol dilute HCl , m sol dilute SO_2 . Gives a blue colouration with FeCl_3 . Dissolves with a red colour in nitric acid

Nitrosamine $\text{C}_6\text{H}_4\text{N}_2\text{O}$ [116°] Yellow needles (from alcohol)

Tetra-methyl-di-amido-diphenyl-amine $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{NH}$ [119°] Obtained by oxidising a mixture of di methyl aniline (1 mol) and di methyl *p* phenylene diamine (1 mol) and reducing the resulting 'dimethyl-phenylene green' (Bundscheidler, *B* 16, 864) Yellowish dimetric tables

Hexa-methyl-tri amido triphenylamine *Tri-methylo trichloride* $(\text{NMe}_2\text{ClC}_6\text{H}_4)_3\text{N}$ Obtained by heating tri amido tri phenyl amine hydrochloride with MeOH at 190° (Heydrich, *B* 19, 758) White needles— $(\text{NMe}_2\text{ClC}_6\text{H}_4)_3\text{N} \cdot 3\text{PtCl}_6$

DI-METHYL AMIDO-PHENYL-BENZYL-AMINE $\text{NMe}_2\text{C}_6\text{H}_4\text{NHCH}_2\text{Ph}$ [48°] Obtained by reducing benzylidene di-methyl phenylene diamine [101°] with sodium amalgam (Kohler, *A* 241, 861) Yellowish plates, ν sol dilute mineral acids, alcohol, ether, benzene, and petroleum ether

Nitrosamine $\text{NMe}_2\text{C}_6\text{H}_4\text{N(NO)CH}_2\text{Ph}$ [128°] Slender yellow needles, sol alcohol

DI-METHYL-AMIDO-DI-PHENYL-CARBINOL $\text{NMe}_2\text{C}_6\text{H}_4\text{CH(OH)C}_6\text{H}_4$ *Di-methyl-amido di-phenyl carbinol* [70°] Formed by reducing di methyl amido benzophenone with sodium amalgam, or by the action of benzoic aldehyde on di methyl aniline (Albrecht, *B* 21, 3292) Thin white needles, insol water, ν e sol ordinary solvents, sl sol petroleum ether

Di-methyl-di-amido di-phenyl-carbinol $\text{NMe}_2\text{C}_6\text{H}_4\text{CH(OH)C}_6\text{H}_4\text{NH}_2$ [165°] Formed by carefully reducing ν nitro di methyl amido di-phenyl-carbinol with zinc dust and HCl (Al-

brecht, *B* 21, 3295) Dissolves in HOAc with blue colouration. Crystallises from benzene in needles containing benzene and melting at 142° . Gives off water (1 mol) when heated above its melting point. Boiling with zinc dust and HCl reduces it to di methyl diamido di phenyl methane [98°]

Tetra methyl di amido-di phenyl carbinol $\text{C}_6\text{H}_4\text{N}_2\text{O} \cdot 2 (\text{NMe}_2\text{C}_6\text{H}_4)_2\text{CH(OH)}$ [96°] Obtained by reducing tetra methyl di amido benzophenone in hot alcoholic solution with sodium amalgam (Michler & Dupertuis, *B* 9, 1899, Nathansohn & Muller, *B* 22, 1879) Colourless trichmic prisms, ν sol alcohol, HOAc , benzene, and ether. Its solution in HOAc is blue, the benzene solution is colourless

Salts— B^*HCl Formed by passing HCl into a solution of the base in ether. Small colourless slender radially grouped needles. In air it turns blue and deliquesces. It is dissociated by water— $\text{B}^*\text{H}_2\text{PtCl}_6$ minute yellow needles, ν sol hot alcohol— $\text{B}^*\text{C}_6\text{H}_5(\text{NO}_2)_2\text{OH}$ dark green crystalline mass, ν sol hot alcohol, sl sol benzene, insol ether

Di-methylo di-iodide $\text{B}^*\text{Me}_2\text{I}_2$ [195°] Small plates (from alcohol), sl sol cold, ν sol hot, alcohol and water, insol benzene and ether

Tetra-methyl di amido-tri-phenyl-carbinol $\text{C}_6\text{H}_4\text{N}_2\text{O} \cdot 2 (\text{C}_6\text{H}_4\text{C(OH)(C}_6\text{H}_4\text{NMe}_2)_2$ [132°] *Malachite green* *Benzaldehyde green*

Formation—1 By the action of dimethyl aniline on benzotrichloride in presence of a metallic chloride (Doebner, *B* 11, 1238, 13, 2222)—2 By the oxidation of a slightly acid solution of tetra methyl di amido tri phenyl-methane with MnO or PbO_2 (E & O Fischer, *B* 12, 796), or with tetra chloro quinone (O Fischer, *A* 206, 130)—3 By heating di methyl aniline (4 pts) with BzCl (2 pts) and ZnCl_2 (3 pts) (Fischer)

Preparation—1 From di methyl aniline (2 mols), ZnCl_2 (half its weight), sand, and benzo trichloride at 100° . The product is distilled with steam and the dye ppd from the aqueous residue by NaCl . The pp is the zinc double chloride, which may be converted by KOH into the base. This is converted into the oxalate which may be purified by crystallisation from water and then decomposed by ammonia (Doebner, *A* 217, 250)—2 By heating benzoic aldehyde (40 g) with dimethylamine (100 g) and 93 p c alcohol (40 g) over a water bath. POCl_3 (65 g) is then added gradually, and when cool the mass is extracted with warm water and the base ppd with NaOH . The yield is nearly theoretical (Nencki, *M* 9, 1148)—3 By heating benzoic aldehyde with ZnCl_2 and di methyl-aniline, and oxidising the resulting leuco base with PbO (Muhlhauser, *D P J* 263, 249)

Properties—Nearly colourless cubes. Insol water. ν sol alcohol forming a green solution. When freshly ppd it is ν sol ether, but when crystalline it is sl sol ether, m sol CS , acetone, benzene or light petroleum

Reactions—1 HClAq at 250° splits it into dimethylamine and di methyl *p* amido benzo phenone—2 On reduction it yields leuco malachite green (tetra methyl di amido tri phenyl-methane) [101°]—3 Fuming HNO_3 in HOAc forms an amorphous hexa nitro derivative

Salts—The salts of organic acids and

neutral salts of mineral acids are green and dye emerald-green. They are v sol water, the oxalate being m sol water and the picrate sl sol water. Concentrated mineral acids turn the solutions orange, forming acid salts. Diluting with water restores the green colour. In the cold, dilute acids dissolve the base, forming a nearly colourless solution, which turns deep green when heated, a molecule of water being probably split off. Thus the hydrochloride becomes

$(\text{C}_{22}\text{H}_{24}\text{N}_2\text{HCl})_2(\text{ZnCl}_2) \cdot 2\text{aq}$ [c 130°] *Malachite green*. Thick, dark green prisms, sol water (Fischer, B 14, 2520) — $\text{C}_{22}\text{H}_{24}\text{N}_2\text{ZnCl}_2 \cdot \text{aq}$ — $\text{C}_{22}\text{H}_{24}\text{N}_2\text{H}_2\text{SO}_4$ — $\text{C}_{22}\text{H}_{24}\text{N}_2\text{H}_2\text{SO}_4 \cdot \text{aq}$ lustrous green prisms — $(\text{C}_{22}\text{H}_{24}\text{N}_2)_2\text{H}_2\text{C}_2\text{O}_4$ *Malachite green*. Large green tables, sol water and alcohol — Picrates $\text{C}_{22}\text{H}_{24}\text{N}_2\text{C}_6\text{H}_5(\text{NO}_2)_3\text{OH}$ (Golden needles (from benzene), insol water — $\text{C}_{22}\text{H}_{24}\text{N}_2\text{C}_6\text{H}_5(\text{NO}_2)_3\text{OH}$ golden needles

Di-methylo-di-iodide $\text{C}_{22}\text{H}_{24}\text{N}_2\text{Me}_2\text{I}_2 \cdot \text{aq}$ [172°] Formed by heating the base with MeI and MeOH at 100° (Doebner). Green plates, sl sol alcohol, ether, benzene, CS_2 , and cold water, v sol hot water. The same compound is obtained by heating di p amido tri phenyl carbinol with MeI and alcohol at 120° (Doebner, B 15, 236)

Ethyl derivative

$\text{C}_6\text{H}_5\text{C}(\text{OEt})(\text{C}_6\text{H}_5\text{NMe}_2)_2$ [162°] From the base by heating with alcohol at 110° (O Fischer, B 12, 1686)

Sulphonic acid $\text{C}_{22}\text{H}_{24}(\text{SO}_3\text{H})\text{N}_2\text{O}$ Green needles with reddish brown lustre, v e sol hot water, forming a green solution — $\text{NaA}^+ - \text{MgA}^+, 4\text{aq} - \text{CaA}^+, 3\text{aq}$

Derivatives v BROMO, CHLORO, NITRO, and OXY TETRA METHYL-DI AMIDO TRI-PHENYL-CARBINOL

Tetra-methyl-ppo-tri-amido-tri phenyl-carbinol $\text{C}_{22}\text{H}_{24}\text{N}_2\text{O} \cdot \text{e}$

$\text{NH}_2\text{C}_6\text{H}_4\text{C}(\text{OH})(\text{C}_6\text{H}_5\text{NMe}_2)_2$ [191°] Formed by oxidation of the acetyl derivative of the leuco base (tetra methyl di p amido o amido tri phenyl methane) with lead peroxide and dilute H_2SO_4 (Fischer a Schmidt, B 17, 1892). Glistening prisms (from ether). The salts are soluble in water with a bluish-green colour.

Tetra methyl tri p amido-tri phenyl carbinol $\text{NH}_2\text{C}_6\text{H}_4\text{C}(\text{OH})(\text{C}_6\text{H}_5\text{NMe}_2)_2$ *Tetra methyl pararosamine*. Obtained by oxidising the acetyl derivative of tetra methyl tri p amido tri phenyl methane with PbO_2 , and boiling the resulting acetyl derivative with HCl (O Fischer a G Körner, B 16, 2904). Small crystals (from ether).

Penta-methyl tri amido tri phenyl carbinol $\text{C}_{22}\text{H}_{24}\text{N}_3\text{O} \cdot \text{e}$ $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C}(\text{OH})\text{C}_6\text{H}_5\text{NHMe}$ *Methyl violet* [180°] Prepared by oxidising dimethylamine with SnCl_4 , with ICl , with HgO_2 and KClO_4 , with KClO_4 , and CuSO_4 , or with NaCl and $\text{Cu}(\text{NO}_3)_2$ (Lauth, *Rep Chim app* 1861, 345, Poirrier a Chappat, *Bt* [2] 6, 502, Hofmann, B 6, 357). Formed also by heating dimethyl aniline with $\text{C}_6\text{H}_5\text{SO}_2\text{Cl}$ at 100° (Hassencamp, B 12, 1275), and, together with formic aldehyde, by shaking hexa methyl tri amido tri phenyl carbinol with MnO_2 , and dilute H_2SO_4 (E a O

Fischer, B 11, 2097). Commercial methyl-violet may be freed from admixed hexa methyl-tri amido tri phenyl carbinol by boiling with ligroin (Wichelhaus, B 16, 2006, 19, 108). Methyl violet occurs in Hofmann's violet.

Properties — Brown powder, melting under water. Insol water, ether, and ligroin. Its alcoholic solution is violet. Its solution in HCl is reddish violet, and is ppd by NaOH , but not by ammonia. Reduced by ammonium sulphide to its leuco base. Tin and HCl reduce it, forming a substance melting at 155°. Boiling HCl splits it up into di methyl aniline and tri-methyl-di amido benzophenone.

Salts — Chloride $\text{C}_{22}\text{H}_{24}\text{N}_3\text{Cl} \cdot \text{e}$ $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C}_6\text{H}_5\text{NMeHCl}$ Amorphous mass,

with green metallic lustre. Its aqueous solution is violet, but on adding HCl it becomes first green, then deep yellowish brown. It dissolves in alcohol. Conc H_2SO_4 forms a yellow solution, which on dilution changes through greenish blue to violet. It dyes silk, wool, and mordanted cotton violet — $\text{C}_{22}\text{H}_{24}\text{N}_3\text{I}$ minute needles.

Picrate $\text{C}_{22}\text{H}_{24}\text{N}_3\text{C}_6\text{H}_5(\text{NO}_2)_3(\text{OH})$ Bronzed needles (from alcohol).

Acetyl derivative Acetate $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C}_6\text{H}_5\text{NMeAc OAc}$ [225°] From

methyl violet, Ac O , and NaOAc (O Fischer a G Körner, B 16, 2905).

Hexa-methyl tri amido-tri phenyl carbinol $\text{C}_{22}\text{H}_{24}\text{N}_3\text{O} \cdot \text{e}$ $(\text{NMe}_2\text{C}_6\text{H}_4)_3\text{COH}$ *Crystal violet*. *Hexa methyl para rosaniline* [195°]

Formation — 1 Together with its methylo-iodide, by heating methyl violet with MeI and MeOH at 120° (Hofmann, B 6, 363). — 2 By the action of dimethylaniline on tetra methyl-di-amido benzophenone in presence of dehydrating agents (Kern a Caro). In this reaction tetra methyl di amido thio benzophenone may also be used. — 3 By the action of COCl_2 , of CICO_2Et , or of CICO CCl_2 , in presence of ZnCl_2 on di-methylaniline. — 4 By condensation of tetra-methyl di amido-di phenyl carbinol with dimethylaniline and oxidation of the resulting leuco base. — 5 By gradually adding tetra chloroquinone (1 pt) to dimethylaniline (2 pts), and heating the product to 65° (Weister, Lucius, a Brunning, B 13, 212, 2100, Wichelhaus, B 16, 2005). Perhaps the substance formed in this case is wholly or partially the penta methyl compound. — 6 By the action of COCl_2 or of CICO_2Et on dimethylaniline in presence of AlCl_3 (Hofmann, B 18, 767, Wichelhaus, B 19, 109).

Properties — Dark reddish violet monoclinic tables. Needles containing benzene (from benzene). Insol water, sol ether, acetone, and ligroin, sl sol alcohol, v e sol chloroform and benzene. Boiling HCl splits it up into dimethylaniline and tetra methyl di amido benzophenone. Aqueous ammonium sulphide reduces it to hexa-methyl tri amido tri phenyl methane.

Salts — Chloride $\text{C}_{22}\text{H}_{24}\text{N}_3\text{Cl} \cdot \text{e}$ $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C}_6\text{H}_5\text{NMeCl}$ Hexagonal crystals,

with greenish brown lustre (Wada, B 18, 768). Sol alcohol. Forms a violet solution in water, which on adding HCl becomes first blue, then green, and finally yellow. NaOH gives a violet pp. Conc H_2SO_4 forms a yellow solution,

changed on dilution through green and blue to violet. Dyes silk, wool, and mordanted cotton bluish-violet— $C_{22}H_{20}N_2Cl$ 8aq crystals, with bronze lustre— $(C_{22}H_{20}N_2Cl)_3PtCl_4$, brick-red crystalline pp, decomposed by water— $C_{22}H_{20}N_2OH_2$, green crystals. At 100° it gives off MeI, becoming the iodide of penta-methyl-tri-amido tri phenyl-carbinol—Picrate $C_{22}H_{20}N_2 \cdot 2C_6H_4(NO_2)_3OH$ yellowish green prisms, with coppery lustre.

Methylo-iodide $C_{22}H_{21}N_2MeI$. From pararosaniline, MeI, and MeOH at 115° (Hofmann, B 6, 365).

TETRA-METHYL-DIAMIDO-DIPHENYL-CUMYL-METHANE $C_{24}H_{26}N_4$, *re* (NMe_2, C_6H_5), $CH_2C_6H_4CH_2$. Prepared by heating cumino aldehyde with dimethylaniline and $ZnCl_2$ to 120° , the yield is about 80 p c. On oxidation it gives a dye stuff closely resembling malachite green.

Salts— $B''H_2Cl$, white crystalline powder— $B''(C_6H_5(NO_2)_2OH)_2$, green crystals, $[156^\circ]$, explodes at 220° — $B''H_2Cl_2PtCl_4$, yellow crystals.

Methylo iodide $B''MeI_2$, white needles $[220^\circ]$. Sl sol cold, v sol hot, water (Zeigler, B 13, 786).

DI-METHYL-AMIDO-PHENYLENE-DI-PHENYL-DIKETONE $NMe_2, C_6H_4(CO C_6H_5)_2$, $[55^\circ]$. From dimethylaniline and $BzCl$ at 180° . Crystals, v sol alcohol and ether.

Hexa-methyl-tri-amido-phenylene-diphenyl-diketone $C_{28}H_{30}N_6O_2$, *re* $NMe_2, C_6H_5(CO C_6H_5, NMe_2)_2$, $[122^\circ]$. From boiling di-methyl aniline and $COCl_2$ (Michler, B 9, 716, Michler a Dupertuis, B 9, 1899). Monoclinic crystals, $a, b, c = 587, 714, \beta = 125^\circ 18'$.

METHYL-AMIDO-PHENYL-ETHANE Nitroso derivative $[41]Et C_6H_5, NMeNO$, $[162^\circ]$. Formed from di-methyl-amido-phenyl-ethane, HCl, and $NaNO_2$ (Heumann a Wiernik, B 20, 2423). Needles, insol water, sl sol ether and cold alcohol. Zinc and HOAc reduce it to ethylphenyl-methyl hydrazine, the acetyl derivative of which melts at 68° .

Di-methyl-amido-phenyl-ethane $[41]Et C_6H_5, NMe_2$, $[89^\circ]$. Formed, together with hexa-methyl-tri-amido-tri-phenyl-methane, by heating glycol (1 mol) with dimethylaniline (2 mols) and $ZnCl_2$ at 100° — 120° (H a W). Needles or prisms (from alcohol), v sol ether, warm alcohol, and benzene, insol water. Its salts are deliquescent, and its platinochloride is unstable. Oxidising agents colour it blue.

Methylo-iodide $Et C_6H_5, NMeI$. From p-amido-phenyl-ethane and MeI (Hofmann, B 7, 527).

Tetra-methyl-di-amido-di-phenyl-ethane $C_{24}H_{28}N_4$, *re* $NMe_2, C_6H_5, CH_2, CH_2, C_6H_5, NMe_2$, $[50^\circ]$ (over 800°). Prepared by heating ethylene bromide with dimethylaniline at 100° (Schoop, B 13, 2196). Slender needles, sol ether, ligroin, hot wood spirit, and alcohol, insol water. With $FeCl_3$ it gives a green colouration, and finally quinone. But it does not yield a dye on oxidation— $B''H_2I_2$. Sol water and alcohol—Oxalate $B''2H_2C_2O_4$ —Picrate $B''C_6H_4(NO_2)_3OH$ yellow pp, sol hot alcohol.

Methylo iodide $C_{24}H_{29}N_4MeI$. From di-amido-di-phenyl-ethane, MeI, and a little KOH at 150° — 180° (Heumann a Wiernik, B 20, 909).

Tetra-methyl-di-amido-tri-phenyl-ethane $C_{26}H_{30}N_4$, $CMc(C_6H_5, NMe_2)_3$. This is the chief product of the action of acetophenone on dimethyl aniline in presence of $ZnCl_2$ (Doebner a Petschoff, A 242, 339). Yellow oil, v sol ether, benzene, petroleum ether, and hot alcohol. It boils above 360° with partial decomposition. It is not volatile with steam.

Hexa-methyl-tri-amido-tri-phenyl-ethane $NMe_2, C_6H_5, CH_2, CH(C_6H_5, NMe_2)_2$, $[125^\circ]$. Formed by heating $CH_3Cl, CHCl_3$ with dimethylaniline and $ZnCl_2$ at 110° — 120° (Heumann a Wiernik, B 20, 2424). White needles, insol water, v sl sol cold, sl sol hot, alcohol, v sol ether. With PbO_2 and HOAc it gives a greenish blue colour.

Octo-methyl-tetra-amido-tetra-phenyl-ethane $C_{28}H_{34}N_8$, *re* (NMe_2, C_6H_5), $CH, CH(C_6H_5, NMe_2)_2$, $[90^\circ]$, (300°) . Formed by heating acetylene tetra-bromide with dimethylaniline at 100° (Schoop, B 13, 2199). Prisms, sol alcohol, ether, and benzene, insol water. With $FeCl_3$ or CrO_3 it produces quinone— $B''2H_2, PtCl_4$, yellow amorphous pp—Picrate $B''C_6H_4(NO_2)_3OH$ yellow plates, sol hot water.

Deca-methyl-penta-amido-penta-phenyl-ethane $C_{30}H_{38}N_{10}$, $[181^\circ]$. Formed by heating a mixture of dimethylaniline (50 g), chloral hydrate (20 g), and $ZnCl_2$ (10 g) at 100° , the yield being 10 g (O Fischer, B 11, 951, A 206, 120, Boessneck, B 18, 1516). Colourless needles (containing aq) (from alcohol), v sol chloroform. Sol benzene, v sl sol alcohol and ether. On oxidation it gives a greenish blue dyestuff.

DI-METHYL- α -AMIDO- ω -DI-PHENYL ETHYL ALCOHOL $NMe, CHPh, CHPh, OH$, $[110^\circ]$. From $NH_2, CHPh, CHPh, OH$, MeI, and EtOH (Goldschmidt a Polonowska, B 20, 494). White needles— $B''_2H_2, PtCl_4, 3aq$.

DI-METHYL-AMIDO-PHENYL-ETHYL-DITHIO-CARBONATE EtO, CS, CH_2, NMe_2 , $[51^\circ]$. Formed from di-methyl-p-phenylene diamine by diazotising and heating the product with aqueous potassium xanthate at 70° (Leuckhart, J pr 42, 41, 206). Light yellow crystals, insol water, sol ordinary menstrua. With alcoholic potash it gives $S(C_6H_5, NMe_2)_2$.

TETRA-METHYL-DI-AMIDO-DI-PHENYL-FURFURYL-METHANE $C_{24}H_{28}O, CH(C_6H_5, NMe_2)_2$, $[83^\circ]$. Prepared by the action of furfuraldehyde on dimethylaniline (O Fischer, B 11, 950).

DI-METHYL-AMIDO-PHENYL GLYOXYLIC ACID $C_{21}H_{21}NO_4$, *re* NMe_2, C_6H_5, CO, CO, H , $[187^\circ]$. Obtained by saponifying its ethyl ether which is produced by adding Cl, CO, CO, Et to dimethylaniline at 100° (Michael a Hanhardt, B 10, 2081). Small plates or needles. Sol water and alcohol— NaA' (dried at 150°). Small needles— BaA_2 (dried at 150°). Plates.

Ethyl ether EtA' , $[95^\circ]$. Yellow plates (from alcohol). Cannot be distilled.

TETRA-METHYL-DI-AMIDO-DI-PHENYL-HEPTANE (NMe_2, C_6H_5), CH, C_6H_5 , $[59.5^\circ]$, (275°) at 15 mm. Formed from dimethylaniline, heptonic aldehyde (menthol) and $ZnCl_2$ (Krafft, B 19, 2987). Crystalline solid, not readily oxidised— $B''H_2, PtCl_4$, yellow crystalline pp, v sl sol water and ether alcohol.

DI METHYL - AMIDO - PHENYL - IMIDO - QUINOLINE TETRAHYDRIDE THIOSULPHONIC ACID

by oxidising a mixture of quinoline tetrahydride (1 mol) with di methyl *p* phenylene diamine thio sulphonic acid (1 mol) by $\text{K}_2\text{Cr}_2\text{O}_7$ (Lellmann & Boye, *B* 23, 1374). Small lustrous green needles, sl sol water. Changes after some time to a brown powder. Zinc dust and HCl reduce it, and the product yields a blue dye on oxidation.

DI METHYL AMIDO PHENYL HEXYL KE

TONE $\text{C}_6\text{H}_5\text{NO} \cdot 12 \text{ NMe C}_6\text{H}_5\text{CO C}_6\text{H}_{11}$, [49°] (190° at 20 mm). Formed, together with the leuco base $\text{C}_{13}\text{H}_{15}\text{N}$, by adding heptyl chloride to a mixture of ZnCl_2 and dimethylaniline (Krafft, *B* 19, 2987, Auger, *Bl* [2] 47, 44). Colourless needles. Gives with conc HNO_3 a nitro compound $\text{C}_{13}\text{H}_{15}\text{CO C}_6\text{H}_4(\text{NO}_2)(\text{NMe}_2)$ [65°].

Oxim $\text{NMe C}_6\text{H}_5\text{C}(\text{NOH})\text{C}_6\text{H}_{11}$, [99°]. Colourless leaflets.

DI METHYL DI AMIDO DI PHENYL KE-TONE**DI METHYL AMIDO PHENYL MERCAP**

TAN $\text{NMe C}_6\text{H}_5\text{SH}$ [28°] (260°). Obtained by reducing tetra methyl di amido di phenyl sulphide with tin and HCl (Merz & Weith, *B* 19, 1575, Leuckart, *J pr* [2] 41, 207). Oil. Dissolves in NaOH aq. Re oxidised by air to $(\text{NMe C}_6\text{H}_5)_2\text{S}$ [118°]— $\text{Pb}(\text{SC}_6\text{H}_5)_2$ plates.

Di methyl di amido phenyl mercaptan

$\text{C}_6\text{H}_5\text{N.S} \cdot 12 \text{ C}_6\text{H}_5(\text{NMe})(\text{NH})(\text{SH})$ [112]. Formed by reducing methylene red (Jacobsen, *B* 21, 3104, Bernthsen, *A* 251, 1). Gives a diazo sulphide $\text{C}_6\text{H}_5(\text{NMe})\text{N}=\text{N}$ [78°].

1 ccI, gives a blue colouration. With AcCl in benzene it gives the hydrochloride of ethenyl-amido dimethylamido phenyl mercaptan $\text{NMe C}_6\text{H}_5\text{N}=\text{N}=\text{CMe} - \text{Zn}(\text{C}_6\text{H}_5)_2\text{N.S}$.

DI-METHYL AMIDO - DI PHENYL METHANE $\text{NMe C}_6\text{H}_5\text{CH C}_6\text{H}_5$. This is perhaps the base, boiling at 335°, produced by heating di methyl aniline benzylo chloride in a sealed tube at 230° (Michler, *B* 10, 2079).

Di methyl di amido-di phenyl methane

$\text{NMe C}_6\text{H}_5\text{CH}_2\text{C}_6\text{H}_5\text{NH}_2$ [93°]. Formed by boiling *p* nitro di methyl amido di phenyl carbinol with zinc dust and HCl (Albrecht, *B* 21, 3296). Colourless needles, coloured bluish violet by PbO_2 or by tetra chloro quinone.

Tetra methyl-di *p* amido di phenyl methane

$\text{C}_6\text{H}_5\text{N} \cdot 12 \text{ CH}_2(\text{C}_6\text{H}_5\text{NMe}_2)$, [91°].

Formation—1 By heating methylene iodide, CHCl_3 or CCl_4 with dimethylaniline (Hanhart, *B* 12, 680, Doebner, *B* 12, 810, cf Hannuman, *B* 10, 1235).—2 By heating methylal $\text{CH}_2(\text{OMe})_2$ (1 mol) with dimethylaniline (2 mols) in presence of ZnCl_2 to 120° (O Fischer, *B* 12, 1689, A 206, 117), or by acting on a mixture of methylal and dimethyl aniline with conc HCl aq (Trüger, *J pr* [3] 86, 237).—3 One of the products of the action of acetophenone or of di ethyl ketone on dimethylaniline in presence of ZnCl_2 (Doebner & Petschhoff, *A* 242, 338).—4 By heating dimethyl-

aniline with CCl_4 , SO_2Cl at 100° (Michler & Moro, *B* 12, 1170).—5 One of the products of the action of (a) naphthylamine sulphonic chloride on dimethylaniline (Michler & Salathé, *B* 12, 1789).—6 From C_6Cl_6 , dimethylaniline and ZnCl_2 (Heumann & Wiernik, *B* 20, 2426).—7 One of the products of the action of zinc and HCl on a mixture of dimethylaniline and CS_2 (Wiernik, *B* 21, 3204, cf Trüger, *J pr* [2] 36, 241).—8 By distilling tetra methyl di amido benzophenone (1 pt) with zinc dust (10 pts) (Nathansohn & Muller, *B* 22, 1882).—9 A product of the action of AcO on dimethylaniline (Reverdin & De la Harpe, *B* 22, 1006).—10 The chief product of the action of methyl hexyl ketone on dimethylaniline (Doebner & Petschhoff, *A* 242, 312).—11 By distilling tetra methyl di amido thio benzophenone with zinc dust (Baither, *B* 20, 1737).

Properties—Four sided tables or glistening leaflets (from alcohol). Insol water, sl sol cold, m sol hot, alcohol, v sol benzene, ether, and CS. Not volatile with steam. On oxidation with HOAc and MnO_2 it gives a fugitive blue colour. When boiled with MnO and H_2SO_4 it yields quinone. Its alcoholic solution is turned blue by boiling with tetra chloroquinone. It may be oxidised to tetra methyl di amido benzophenone (N & M). Conc HNO_3 in HOAc forms a tetra-nitro derivative which decomposes at 218°. With tri nitro benzene it forms a compound $\text{C}_6\text{H}_5\text{N}(\text{NO}_2)_3$, [114°], and with *m* di nitro benzene a compound $(\text{C}_6\text{H}_5\text{N})_2\text{C}_6\text{H}_3(\text{NO}_2)_2$, [74°] (Van Romburgh, *R T C* 7, 226).

Salts— $\text{B}^+\text{H}^-\text{I}^-$ sparingly soluble tables. $\text{B}^+\text{H}^-\text{PtCl}_6^-$ yellow precipitate—Picrate $\text{B}^+\text{C}_6\text{H}_5(\text{NO}_2)_3\text{OH}$ [178°].

Methylo iodide B^+MeI^- , [211°]. Yellow plates, v sol hot water and alcohol, insol ether (D & P).

Tetra - methyl - *cro* - *pp* - tri - amido - di-phenyl methane $(\text{NMe C}_6\text{H}_5)_3\text{CHNH}$, [135°]. Obtained by reducing the imide of tetra methyl di amido benzophenone (auramine) with sodium amalgam (Græbe, *B* 20, 3265). Colourless crystals, v sl sol water, m sol alcohol. Gives an intense blue colouration with HOAc.

Methyl *cro* amido tri phenyl methane

$\text{C}_6\text{H}_5\text{N} \cdot 12 \text{ C}_6\text{H}_5\text{CNHMe}$ [73°]. Obtained by passing methylamine into a hot solution of Ph_3CBr in benzene (Hemlin & Silberstein, *B* 17, 745). Prisms (from ligron). Insol water, v sol alcohol— $\text{B}^+\text{H}^-\text{PtCl}_6^-$ 6aq— B^+I^- Ppd as lustrous blue black needles by adding iodine to its solution in CS.

Di methyl-*cro* amido tri phenyl-methane

$\text{C}_6\text{H}_5\text{N} \cdot 12 \text{ C}_6\text{H}_5\text{CNMe}_2$, [97°]. From *cro*-bromo tri phenyl methane and NHMe_2 in benzene (H & S). Insol water, v sol alcohol— $\text{B}^+\text{H}^-\text{PtCl}_6^-$.

Di-methyl amido tri-phenyl-methane $\text{C}_6\text{H}_5\text{N} \cdot 12 \text{ C}_6\text{H}_5\text{CH C}_6\text{H}_5\text{NMe}_2$, [132°]

Formation—1 By heating di phenyl carbinol with di methyl aniline and P_2O_5 at 150° (O Fischer, *B* 11, 951, 12, 1690, A 206, 114).—2 By heating benzophenone chloride Ph_2CCl_2 with dimethylaniline and ZnCl_2 (F., cf Pauly, *A* 187, 209).

Preparation—Benzophenone (10 g), dimethylaniline (13 g), and zinc chloride (10 g)

are heated in sealed tubes for ten hours to 190°. After driving over excess of dimethylaniline and benzophenone the residue is extracted with ether, and after distilling this off the base is recrystallised from alcohol (Doebner & Petschow, *A* 242, 342).

Properties—Colourless needles, sl sol alcohol, v sol ether and benzene. Does not give a colouring matter on oxidation. Is a weak base, and does not combine with HOAc.

Salts— B^+HCl^- , $B^+H_2PtCl_6^-$, needles, sl sol hot water.

Methylo-iodide $C_{21}H_{21}NMeI$ [186°] Large white plates.

Tetra-methyl-di-amido-tri-phenyl methane $C_{25}H_{25}N_2$, *ie* $(NMe_2.C_6H_5)_3CH.C_6H_5$. *Leuco base of malachite green* [102°] and [94°].

Formation—1 By heating a mixture of benzoic aldehyde (10 pts) and dimethylaniline (23 pts) with $ZnCl_2$. The yield is 90 p.c. (O Fischer, *B* 10, 799, 1624, 11, 950, 2274, 12, 1685, *A* 206, 122).—2 From benzylidene chloride, dimethylaniline, and $ZnCl_2$.—3 By heating di-amido tri phenyl methane with MeI and MeOH at 130° (F).—4 By heating its carboxylic acid (di methyl-aniline phthalin) $(NMe_2.C_6H_4)_2CH.C_6H_4.CO_2H$ with barium hydride.—5 From tetra-methyl di amido tri-phenyl-carbinol (malachite green) by reduction with zinc-dust and HCl (Doebner, *B* 11, 1239, *A* 217, 256).—6 A by-product in the action of phthalyl chloride and in that of benzoyl chloride on dimethylaniline.—7 By heating phenyl-glyoxylic acid with dimethylaniline and $ZnCl_2$ (Peter, *B* 18, 539).—8 A by-product in the action of $ZnCl_2$ on a mixture of dimethylaniline and acetophenone (Doebner & Petschow, *A* 242, 333).

Preparation—A mixture of benzoic aldehyde (40 g), dimethylaniline (100 g), and 93 p.c. alcohol (40 g) is heated on a water bath, and $POCl_3$ (56 g) added slowly. The product is extracted with water, the filtrate ppd. by soda and the pp recrystallised from alcohol (Nencki, *M* 9, 1148).

Properties—Crystallises from benzene in [apparently triclinic] needles, melting at 102°, and from alcohol in triclinic leaflets, melting at 94° (E & O Fischer, *B* 12, 796). Insol water, v sol ether and benzene, sl sol petroleum. In small quantities it can be distilled. Its salts are oxidised by MnO_2 or PbO_2 to malachite green. Nitric acid forms a hexa nitro derivative [200°]. When distilled with zinc dust it is reduced to aniline, dimethylaniline, and *p* amido di-phenyl-methane (Manns, *C* 1888, 1363).

Salts— $B^+H_2Cl_2^-$, colourless hygroscopic needles, v sol water. Gives off HCl at 100°, becoming B^+HCl^- . $B^+H_2PtCl_6^-$, white pp, soon becoming yellowish green.—The aurochloride is a golden-yellow flocculent pp.—Picrate $B^+2C_6H_5(NO_2)_3OH^-$ [220°]. Aggregations of needles, m sol water.

Di-methylo-di-iodide $B^+Me_2I_2^-$ [218°–222°] (F), [231°] (Doebner, *B* 13, 2228). Plates, tables, or leaflets, v sol water. Decomposed on fusion into MeI and the base.

Tetra-methyl-ppo tri-amido-tri-phenyl-methane $([4]1)NMe_2.C_6H_5)_3CH.C_6H_5.NH_2$ [12] [185°] *o*-Amido-leuco-malachite green. Formed by reducing, by means of zinc-dust and HCl, the

product of the condensation of *o* nitro benzoic aldehyde with dimethylaniline (Fischer & Schmidt, *B* 15, 683, 17, 1891). Colourless crystals (containing C_6H_5). Gives a reddish brown dye stuff on oxidation.

Acetyl derivative $C_{25}H_{25}(NMe_2)_2(NHAc)$. [186°] Glistening crystals. Gives on oxidation $(NMe_2.C_6H_5)_3C(OH).C_6H_5.NHAc$.

Tetra-methyl-tri-amido-tri-phenyl-methane $C_{25}H_{25}N_3$, *ie* $(NMe_2.C_6H_5)_3CH.C_6H_5.NH$ [65°] Prepared by dissolving tetra methyl di *pp* amido di phenyl carbinol (20 pts) in $HClAq$ (12 pts of $S.G.$ 1.18) and water (100 pts), heating to 100°, and adding aniline hydrochloride (10 pts) (Nathansohn & Muller, *B* 22, 1886). Small needles (from warm alcohol), v sol alcohol, ether, and benzene, insol water. According to analogy it should be identical with the preceding body. With MeI it gives $CH(C_6H_5.NMe_2)_3I$, [172°].

Salts— $B^+H_2Cl_2^-$, yellowish green crystalline pp, got by adding HCl to an ethereal solution of the base. V sol hot alcohol, sl sol ether, insol benzene.— $B^+H_2PtCl_6^-$, light yellow flocculent pp, v sl sol water and alcohol.—Picrate $B^+C_6H_5(NO_2)_3OH^-$, light green flocculent pp, v sol hot alcohol, insol benzene and ether.

Benzoyl derivative $(NMe_2.C_6H_5)_3CH.C_6H_5.NHBz$ [128°] Small, slender blue plates (from warm alcohol), v sol hot alcohol and benzene, sl sol ether, insol water.

Tetra-methyl-ppm-tri-amido-tri-phenyl-methane $([4]1)NMe_2.C_6H_5)_3CH.C_6H_5.NH$ [13] [130°] Prepared by reducing *m* nitro tetra methyl-di amido tri phenyl carbinol (E & O Fischer, *B* 12, 803). Colourless prisms or needles. Gives a green dye on oxidation.

Tetra-methyl tri *p* amido tri phenyl methane $C_{25}H_{25}N_3$, *ie* $([4]1)NMe_2.C_6H_5)_3CH.C_6H_5.NH$ [14] [152°] Prepared by reducing the hydrochloride of *p* nitro tetra methyl di-*p* amido tri phenyl methane with zinc dust (Fischer, *B* 14, 2527). Colourless plates, sl sol alcohol. Gives on oxidation tetra methyl pararosaniline, a reddish violet dye.

Acetyl derivative [108°] Needles. Yields on oxidation the corresponding carbinol, a splendid green dye (Fischer & German, *B* 16, 708).

Penta methyl tri *p* amido tri phenyl methane $C_{25}H_{25}N_4$, *ie* $(NMe_2.C_6H_5)_3CH.C_6H_5.NMeH$ [116°] Obtained by heating tetra methyl pararosaniline with alcoholic ammonium sulphide at 100° (Hofmann, *B* 6, 360, E & O Fischer, *B* 12, 799, Fischer & Körner, *B* 16, 2906). Large colourless needles (from alcohol). Sl sol hot water, v sol alcohol and ether.— $B^+3H_2PtCl_6^-$.

Acetyl derivative [143°] **Hexa-methyl-tri-amido-tri-phenyl methane** $C_{25}H_{25}N_6$, *ie* $HC(C_6H_5.NMe_2)_3$. **Hexa methyl-paraleucaniline** [173°].

Formation—1 By treating chloral with dimethylaniline and $ZnCl_2$ (E & O Fischer, *B* 11, 2097). The base so prepared melted, however, at 250°.—2 From orthoformic ether (1 pt) and di methylaniline ($\frac{3}{2}$ pts) at 100° (Fischer & Knorr, *B* 17, 98).—3 By condensation of *p* di methyl-amido benzaldehyde with di methyl aniline in presence of dry HCl gas or $ZnCl_2$ (Boess-

neck, *B* 19, 566) — 4 From glycol, dimethyl-aniline, and ZnCl_2 at $100^\circ\text{--}120^\circ$ (Heumann a Wiernik, *B* 20, 2421) Needles or prisms When oxidised with MnO_2 and H_2SO_4 it gives formic aldehyde and methyl violet (Fischer)

Tri-methylo-tri-iodide $\text{C}_{12}\text{H}_{12}\text{N}_3\text{I}_3$ s.e. $\text{CH}(\text{C}_6\text{H}_5, \text{NMe}_2)_3$ [185°] From tetra- and hexa methyl-tri-*p*-amido-tri-phenyl methane, MeI, and MeOH at 100° (Hofmann a Girard, *B* 2, 448, Fischer, *B* 12, 2844) Yellow needles (containing aq), decomposes and becomes dark blue on fusion Gives $(\text{C}_{12}\text{H}_{12}\text{N}_3\text{Cl}_3) \cdot 3\text{PtCl}_2 \cdot 2\text{aq}$

Hexa-methyl opp (?) tri-amido-tri-phenyl-methane Tri-methylo-tri-iodide $\text{CH}(\text{C}_6\text{H}_5, \text{NMe}_2)_3$ [172°] Obtained by heating the corresponding tetra methyl tri-amido tri phenyl methane with MeI (Nathansohn a Muller, *B* 22, 1987) Small brown needles (from warm alcohol), v sol alcohol and hot water, almost insol ether and benzene

Hexa-methyl mpp tri-amido-tri-phenyl-methane Tri-methylo-tri-iodide $(3 \frac{1}{2}) \text{NMe}_2 \cdot \text{I} \cdot \text{C}_6\text{H}_5, \text{CH}(\text{C}_6\text{H}_5, \text{NMe}_2)_3$ [141°] Formed by heating the base $\text{C}_{12}\text{H}_{12}\text{N}_3$ or the corresponding $\text{CH}(\text{C}_6\text{H}_5, \text{NH}_2)_3$ with MeI and MeOH at 120° (Fischer, *B* 12, 802, 13, 673) Crystallises with difficulty, and is v sol water Gives rise to $8\text{PtCl}_2 \cdot 2\text{CH}(\text{C}_6\text{H}_5, \text{NMe}_2)_3$

References—CHLORO-, CHLORO-NITRO-, and NITRO-, METHYL-AMIDO-PHENYL-METHANES

TETRA METHYL DI-AMIDO TRI-PHENYL-METHANE CARBOXYLIC ACID $\text{C}_{12}\text{H}_8\text{N}_2\text{O}_4$ s.e. $(\text{NMe}_2, \text{C}_6\text{H}_5)_2\text{CH} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$ *Di-methyl aniline phthalin* [200°] Obtained by treating di-methyl-amido phthalide with zinc-dust and HCl (Fischer, *A* 206, 101) Formed also by treating *p*-aldehyde benzoic acid with dimethylaniline and ZnCl_2 (Löw, *A* 231, 367) Plates (from alcohol), v sol ether, sl sol ligroin, m sol alcohol Conc H_2SO_4 forms a bluish violet solution Its zinc salt melts at 147° (L) —Platinochloride $\text{C}_{12}\text{H}_8\text{N}_2\text{O}_4 \cdot \text{H}_2\text{PtCl}_6$ —Picrate $\text{C}_{12}\text{H}_8\text{N}_2\text{O}_4 \cdot \text{C}_6\text{H}_5(\text{NO}_2)_3\text{OH}$

TETRA METHYL DI-AMIDO TRI-PHENYL-METHANE CARBOXYLIC ALDEHYDE $\text{C}_{12}\text{H}_8\text{N}_2\text{O}_3$ s.e. $(\text{NMe}_2, \text{C}_6\text{H}_5)_2\text{CH} \cdot \text{C}_6\text{H}_4 \cdot \text{CHO}$ From terephthalic aldehyde, dimethylaniline, alcohol, and ZnCl_2 (Löw, *A* 231, 381) Needles (from chloroform) Sl sol alcohol, m sol benzene, v sol chloroform Its phenylhydrazide melts at 22° — $\text{B}''\text{H}_2\text{PtCl}_6$

DI-METHYL-AMIDO-PHENYL (a)-NAPHTHYL SULPHONE $\text{C}_{12}\text{H}_8\text{N}_2\text{SO}_2$ s.e. $\text{NMe}_2, \text{C}_6\text{H}_5, \text{SO}_2, \text{C}_{10}\text{H}_7$ Formed, together with tetra methyl di-amido di-phenyl methane, by heating dimethylaniline (2 mols) with the chloride of naphthalene (a) sulphonic acid (Michler a Salathé, *B* 12, 1789) Crystals, v sol alcohol and ether Conc HClO_4 at 180° splits it up into naphthalene, H_2SO_4 , aniline, and MeCl Zinc and H_2SO_4 give dimethylaniline and naphthyl mercaptan Fuming HNO_3 gives tetra nitro methyl aniline and nitro naphthalene sulphonic acid

Di-methyl-amido-phenyl (b)-naphthyl sulphone Resembles the preceding body in its mode of preparation, properties, and decompositions (M a S)

DI-METHYL-*p*-AMIDO-PHENYL-OXAMIC ACID $\text{C}_{12}\text{H}_{12}\text{N}_2\text{O}_4$ s.e. $\text{NMe}_2, \text{C}_6\text{H}_5, \text{NH} \cdot \text{CO} \cdot \text{CO}_2\text{H}$ [192°] The ethyl ether is formed by boiling di-

methyl-*p*-phenylene diamine with oxalic ether, and separated by solution in alcohol from the accompanying tetra methyl di-amido-di-phenyl oxamide (Sendtner, *B* 12, 530) The ether is then saponified by alcoholic KOH. Needles (from water) or plates (from alcohol)

Ethyl ether EtA' [177°] Yellow plates or needles, v sol warm alcohol

DI-METHYL-AMIDO-PHENYL-OXAMIDE $\text{C}_{12}\text{H}_{12}\text{N}_2\text{O}_3$ s.e. $\text{NMe}_2, \text{C}_6\text{H}_5, \text{NH} \cdot \text{CO} \cdot \text{CO} \cdot \text{NH}_2$ [259°] Formed by treating di-methyl-amido-phenyl-oxamic ether with alcoholic NH_3 (Sendtner, *B* 12, 532) Nodules (from alcohol) — $\text{B}''\text{H}_2\text{SO}_4$ crystals

Tetra-methyl-di-amido-di-phenyl oxamide $\text{NMe}_2, \text{C}_6\text{H}_5, \text{NH} \cdot \text{CO} \cdot \text{CO} \cdot \text{NH} \cdot \text{C}_6\text{H}_5, \text{NMe}_2$ Formed as described under di-methyl-amido-phenyl-oxamic acid (Sendtner) Small yellow needles, insol water, sl sol boiling alcohol Does not melt at 270° Diacid base, forming salts soluble in water

TETRA-METHYL-DI-AMIDO-DI-PHENYL OXIDE $\text{C}_{12}\text{H}_8\text{N}_2\text{O}$ s.e. $(\text{NMe}_2, \text{C}_6\text{H}_5)_2\text{O}$ [119°] Formed by boiling the corresponding sulphide ('thiodimethylaniline') with an ammoniacal alcoholic solution of AgNO_3 (Holzmann, *B* 21, 2056) Stellate groups of colourless needles, insol water, sl sol cold alcohol, ether, and benzene Readily soluble in acids Conc HClO_4 at 200° gives MeCl and aniline — $\text{B}''\text{H}_2\text{PtCl}_6$, minute bright yellow plates, sl sol hot alcohol —Picrate $\text{B}''\text{C}_6\text{H}_5(\text{NO}_2)_3\text{OH}$ [150°] Small yellow needles, sl sol cold alcohol and benzene

Tetra methyl di-amido di-phenyl-di-oxide $(\text{NMe}_2, \text{C}_6\text{H}_5)_2\text{O}_2$ *Di-oxo di-methyl aniline* [91°] Obtained by adding (4 mols of) silver nitrate to an alcoholic solution of tetra methyl di-amido di-phenyl-di-sulphide $(\text{NMe}_2, \text{C}_6\text{H}_5)_2\text{S}_2$ (1 mol) treated with conc NH_3 It is also formed by the action of FeCl_3 upon the conc HCl solution of the same base Thin silky needles, or plates V sol alcohol, ether, and benzene, sol hot water It dissolves in acids, but its salts are not crystalline (Merz a Weith, *B* 19, 1573)

TETRA METHYL DI-AMIDO DI-PHENYL-OXINDOLE $\text{C}_{12}\text{H}_8\text{N}_2\text{O}$ s.e. $\text{C}_6\text{H}_5 - \text{C}(\text{O}, \text{H}, \text{NMe}_2)_2$

Di-methyl aniline-NH-CO isatin [234°] Formed by heating isatin with dimethylaniline and ZnCl_2 (Baeyer a Lazarus, *B* 18, 2642) Glistening colourless prisms Sl sol ether, alcohol, and ligroin, insol water Dissolves in acids On oxidation it gives a splendid bluish green dye stuff

DI-METHYL-AMIDO TRI-PHENYL-PHOSPHINE $\text{C}_{12}\text{H}_{12}\text{NP}$ s.e. $\text{NMe}_2, \text{C}_6\text{H}_5, \text{P}(\text{C}_6\text{H}_5)_2$ [152°] Formed by the action of sodium on a mixture of chloro benzene and $\text{NMe}_2, \text{C}_6\text{H}_5, \text{PCl}_2$ (Schenk a Michaelis, *B* 21, 1502) Colourless crystals, v sol benzene, sl sol alcohol and ether Weak base, being almost entirely ppd by water from its solution in HClO_4

Hexa methyl tri-amido tri-phenyl-phosphine $(\text{NMe}_2, \text{C}_6\text{H}_5)_3\text{P}$ [273°] Formed by heating dimethylaniline with PCl_3 in a sealed tube (Hannemann, *B* 9, 845) Formed also as a by product, in the action of PCl_3 on dimethylaniline in presence of AlCl_3 (S a M.) Colourless needles,

which turn blue on exposure to air V e sol chloroform, v sol dilute HCl aq, m sol hot alcohol

DI-METHYL-AMIDO-PHENYL PHOSPHINOUS ACID ν **DI-METHYL AMIDO BENZENE PHOSPHINIC ACID**

TETRA-METHYL-DI-AMIDO-DI-PHENYL-PHTHALIDE $C_{24}H_{24}N_4O_4$, $t.c$

$(NMe_2C_6H_4)_2C \begin{smallmatrix} O \\ \diagup \diagdown \\ O \end{smallmatrix} CO$ *Dimethylaminophthalate* [191⁷] Prepared by heating dimethylaniline with $ZnCl_2$ and phthalyl chloride or phthalic anhydride (O Fischer, *B* 9, 1758, 10, 952, 12, 1691, *A* 206, 92) Colourless pointed crystals, insol water, v sol benzene, v sl sol ligrom Reduced by zinc dust and $HOAc$ to tetra methyl di amido tri phenyl methane carboxylic acid (dimethylaniline phthalin) Potash-fusion gives dimethylaniline, $HOBz$, and phthalic acid HNO_3 gives a hexa-nitro-derivative which decomposes at 230°

Salts— $B'HCl$ small needles, m sol water — $B'H_2Cl_2$ hygroscopic crystalline mass, got by passing HCl into the ethereal solution Gives off HCl (1 mol) at 100° — $B''H_2PtCl_6$ crystal line pp — $B''H_2PtCl_6$ aq prisms — Picrate $B''2C_6H_3(NO_2)_3OH$

Methylo-vodide $B''Me_2I_2$ [c 185°]

Phthal green $C_{24}H_{24}N_4O_4$ This substance, isomeric with the preceding, is also formed in the action of phthalyl chloride on di methylaniline in presence of $ZnCl_2$ (Fischer) Its hydrochloride, $B'HCl$, forms greenish yellow needles, m sol water Its zinc double salt crystallises in brass yellow needles which form a green solution in water Zinc and HCl reduce it to a leuco-base $C_{24}H_{24}N_4O_4$ which crystallises in small prisms [236°], and is easily re-oxidised to phthal green

TETRA METHYL-DI-AMIDO PHENYL-DI-PHENYLENE-OXIDE-CARBINYL CHLORIDE

$C_6H_5C \begin{smallmatrix} C_6H_4NMe_2 \\ \diagup \diagdown \\ C_6H_4NMe_2Cl \end{smallmatrix} O$ *Tetra methyl-rosamine*

me Formed from benzotrichloride and dimethyl-*m* amidophenol at 50° – 60° (Heumann a Rey, *B* 22, 3002) Dark red flocculent pp, strongly fluorescent in acid or neutral solution H_2SO_4 dissolves it giving an orange yellow colour, becoming dark-red on addition of water Silk and wool are dyed in feebly acid bath rose to bluish red

Salts— $B'HCl$ dark red needles with steel-blue reflex, v sol water and $EtOH$ forming solutions with a splendid blue red colour, and yellow fluorescence — $(C_6H_4N_2OCl)_2PtCl_6$ dark-red pp

DI-METHYL-AMIDO-PHENYL-PROPANE $C_{11}H_{17}N$ $t.c$ $NMe_2C_6H_4CH_2CH_2CH_3$ *Di methyl amido propyl benzene* (230°)

From p bromo-di methyl-aniline, propyl bromide, and sodium (Claus a Howitz, *B* 17, 1327) Oil

Methylo-vodide $NMe_2IC_6H_4Pr$ [168°]

Tetra-methyl-di-amido-di-phenyl-propane $(NMe_2C_6H_4)_2CMe_2$ [88°] From acetone (1 mol), dimethylaniline (2 mols), and $ZnCl_2$ (Doebner, *B* 12, 813) Long needles

DI-METHYL-AMIDO-PHENYL-QUINON-

IMIDE $C_{14}H_9N_2O$ $t.c$ $C_6H_4 \begin{smallmatrix} O \\ \diagup \diagdown \\ N C_6H_4NMe_2 \end{smallmatrix}$ *Phenol-blue*. Formed by adding quinone chlor-

imide to a solution of di methyl aniline in concentrated aqueous oxalic acid (Fogh, *B* 21, 889). Formed also by the action of $NaOH$ on di methyl phenylene green (Möhlau, *B* 18, 2914) Black crystals (containing $\frac{1}{2}$ aq) Yields, when treated with hot dilute HCl aq, quinone and dimethyl phenylene p diamine May be reduced to a leuco-base

Sulphonic acid

$SO_3H C_6H_4 \begin{smallmatrix} O \\ \diagup \diagdown \\ M C_6H_4NMe_2 \end{smallmatrix}$ Formed by passing

chlorine into amido phenol sulphonic acid suspended in water, and then adding di methyl-aniline (F) Slender needles, v sl sol hot alcohol, insol cold water and ether Its alkaline solutions are blue Conc H_2SO_4 forms a cherry red solution

TETRA-METHYL DI-AMIDO DI PHENYL SULPHIDE $(NMe_2C_6H_4)_2S$ *Thiodimethylaniline* [126°] Formed by heating dimethyl aniline with persulphocyanic acid or SCl_2 (Tur sin, *B* 17, 584, Holzmann, *B* 20, 1640, 21 2056, Michaelis a Godehaux, *B* 23, 554) Light-yellow needles, sl sol alcohol and benzene

Reactions — 1 Silver nitrate converts it into $(NMe_2C_6H_4)_2O$ — 2 On heating with reduced copper (10 pts) at 300° it yields $NPhMe$

Salts — $B''H_2Cl_2$ [176°] White mass becoming coloured in the air, extremely sol water — $B''H_2PtCl_6$ 2aq — $B''H_2FeCl_6$ 6aq white powder, m sol water — $B''C_6H_3(NO_2)_3OH$ [142°] Yellow needles (from hot alcohol) — $B''2C_6H_3(NO_2)_3OH$ Amorphous [146°] — $B''HNCs$ [168°], pearly plates

Tetra-methyl-di-amido-di-phenyl-di-sulphide $(NMe_2C_6H_4)_2S_2$ *Di sulphido- or di thio di methyl aniline* [118°] Formed by adding

S_2Cl_2 , diluted with petroleum ether, to a dilute solution of dimethylaniline in the same solvent (Merz a Weith, *B* 19, 1570) Formed also by heating di methyl p amido phenyl ethyl di thio carbonate with an alcoholic solution of aniline at 200° (Leuckart, *J pr* [2] 41, 208) Small yellow needles, e sol CS_2 , more sparingly in hot benzene, alcohol, and petroleum ether, nearly insol water Copper powder removes the sulphur at c 230° forming dimethylaniline and other products By the action of Fe_2Cl_6 , or of alcoholic NH_3 and silver nitrate, it is converted into tetra methyl di amido di phenyl di oxide $(NMe_2C_6H_4)_2O_2$ By tin and HCl , or by sodium amalgam, it is reduced to di methyl-amido phenyl mercaptan, which is readily re-oxidised to the di sulphide Its salts are gummy and amorphous, they are decomposed by water

Tetra-methyl-tetra-amido-di phenyl-disulphide $(NMe_2C_6H_4(NH_2))_2S_2$ Formed by atmospheric oxidation from di methyl-di-amido phenyl mercaptan $NMe_2C_6H_4(NH_2)SH$ (Bernthsen, *A* 251, 1) Thick oil, sol ether, alcohol, and benzene Dissolves in acids, but reppd by alkalis In benzene solution it combines with sulphur forming a persulphide [97°], apparently $C_{24}H_{24}N_8S_3$

DI-METHYL AMIDO-DI-PHENYL SULPHONE $C_{14}H_9SO_2C_6H_4NMe_2$ [78°] (R), [82°] (M a M) Formed by heating dimethylaniline with benzene sulphonic chloride (Möhler, *B* 10, 1742, Van Romburgh, *R T C* 2, 805, Michler a. Meyer, *B* 12, 1791, Hassencamp, *B* 12,

1275) Needles (from alcohol), insol water, v e sol alcohol, ether, and benzene HClAq at 180° splits it up into MeCl, aniline, and benzene Zinc and H₂SO₄ reduce it to phenyl mercaptan and dimethylamine HNO₃ gives yellow crystals of tetra nitro-methyl aniline [127°]

METHYL-AMIDO-PHENYL-THIAZOLE

ω bromo acetophenone and methyl thio urea (Traumann, *A* 249, 46) Yellow plates (from ether), insol water, m sol alcohol With HClAq at 220° it yields methylamine

TETRA METHYL DI AMIDO-DI-PHENYL-THIENYL METHANE

$\text{C}_{24}\text{H}_{24}\text{N}_4\text{S}_2$ i.e. (NMe₂, C₆H₄), CH C₆H₅ *Thiophene leuco-malachite green* [93°] Formed by heating thiophene aldehyde with dimethylaniline, ZnCl₂, and a little alcohol (Peter, *B* 18, 538, Levi, *B* 20, 514) Formed also by heating dimethyl aniline with thienyl glyoxylic acid C₆H₅ CO CO₂H and ZnCl₂ (P) Needles, insol water, v sol alcohol and ether The alcoholic solution turns green in the air MnO₂ and dilute H₂SO₄ oxidise it to the carbinol (NMe₂, C₆H₄), C(OH) C₆H₅, which is a dark brown oil, sol alcohol and ether, and forming salts which dye a splendid yellowish green (*Thiophene green*)—Platinichloride C₂₄H₂₄N₄SH₂PtCl₆—Picrate C₂₄H₂₄N₄S₂C₆H₃(NO₂)₃(OH) [c 208°] Yellowish green needles, sl sol cold water, v sol alcohol

Di-methylo di iodide

C₆H₅S CH(C₆H₅, NMe₂)₂ [212°] White plates

TETRA METHYL-DI-AMIDO DI-PHENYL-THIOKETONE v TETRA METHYL DI AMIDO-THIO BENZOPHENONE

DI-METHYL DI AMIDO PHENYL THIO-SULPHURIC ACID NMe₂, C₆H₄(NH₂)₂S SO₂H [193°-204°] Obtained by adding an alkali to a $\frac{1}{10}$ p.c solution of methylene red until the colour is destroyed, then acidulating with HOAc and exposing to the air Formed also by the action of a strong solution of SO₂ on di-methyl di-amido phenyl mercaptan (Bernthsen, *A* 251, 1) Crystals, sl sol water and alcohol Its dilute aqueous solution gives a purple colour with traces of iodine or of FeCl₃ The hydrochloride crystallises in prisms

Reactions—1 A mixture of di-methyl di-amido phenyl thio sulphuric acid with dimethyl aniline when oxidised by K₂Cr₂O₇ and HOAc

forms the indamine $\text{C}_8\text{H}_7\text{N} \begin{array}{c} \text{N} \\ | \\ \text{C}_6\text{H}_4(\text{NMe}_2) \end{array} \text{S}$, an

emerald green powder (containing 3aq), and yields NMe₂, C₆H₄NH C₆H₄(NMe₂) S SO₂H on reduction, a body which is v sol hot alcohol and acids—2 A mixture of the thio-sulphuric acid with aniline hydrochloride gives on oxidation

$\text{C}_{11}\text{H}_{11}\text{N}_2\text{S}_2\text{O}_2$ i.e. $\text{C}_6\text{H}_5 \begin{array}{c} \text{N} \\ | \\ \text{C}_6\text{H}_4(\text{NMe}_2) \end{array} \text{S} (?)$ an

insoluble green compound decomposed by water Prolonged boiling with dilute FeCl₃ gives

$\text{C}_6\text{H}_5 \begin{array}{c} \text{N}(\text{NMe}_2) \\ | \\ \text{NH} \end{array} \text{S}$, a blue powder with bronze

lustre—3 A mixture of di-methyl-di-amido-phenyl thiosulphuric acid with o-toluidine yields

on oxidation the homologous C₁₃H₁₁N₂S₂O₄ as a bluish grey powder

Tetra-methyl-di-amido phenyl thiosulphuric acid C₆H₄(NMe₂)₂S SO₂H [175°-182°] Obtained by dissolving tetra methyl p phenylene diamine (27 g) in HCl (156 c.c of 38 p.c) and adding aluminum sulphate (10 g), and sodium thiosulphate (66 g) dissolved in water (36 c.c) A cold solution of K₂Cr₂O₇ (25 c.c of a 6.67 p.c solution) is then added, and the resulting liquid left to stand The precipitate which then separates is recrystallised from alcohol (Bernthsen, *A* 251, 60) Plates, sol hot water and acids Zinc and HCl reduce it to the mercaptan C₆H₄(NMe₂)₂SH

TETRA-METHYL DI p-AMIDO-DI-PHENYL

THIO UREA C₁₂H₁₂N₂S i.e. (NMe₂, C₆H₄, NH)₂S [186°] Formed by boiling di-methyl-p phenylene diamine with alcoholic CS₂ (Baur, *B* 12, 533) White needles, insol water and cold alcohol—B'H₂Cl₂ crystalline powder

Acetyl derivative [71°] White plates

TETRA-METHYL-DI-AMIDO-DI-ω-PHE-

NYL-TOLUIC ALDEHYDE C₂₄H₂₄N₄O i.e. (NMe₂, C₆H₄), CH C₆H₄CHO *Aldehyde of the leuco base of malachite green* [143°] Obtained by boiling an alcoholic solution of terephthalic aldehyde C₆H₄(CHO)₂ with di-methyl aniline and ZnCl₂ (W Löw, *A* 231, 381) Prismatic needles (from chloroform) Forms a crystalline compound with NaHSO₃ Its phenyl hydrazide melts at 225°—B'H₂PtCl₆

TRI METHYL-TRI AMIDO-DI-PHENYL-

TOLYL CARBINOL C₂₄H₂₄N₃O Formed by heating rosaniline chloride (1 pt) with MeI (2 pts), MeOH (8 pts), and KOH (1 pt) (Hofmann) Formed also by allowing an alcoholic solution containing rosaniline and 'iodine green' to stand in the cold (Girard a Willm, *Bl* [2] 25, 200)

The salt NHMe C₆H₃Me C $\begin{array}{c} \text{C}_6\text{H}_4\text{NHMe} \\ | \\ \text{C}_6\text{H}_4\text{NHMe} \end{array}$ Cl is one

of the substances known as Hofmann's violet (Hofmann, *C R* 54, 428, 56, 945, 1033, 57, 1131) Its absorption spectrum has been studied by Hartley (*C J* 51, 172)

Penta-methyl-tri-amido di-phenyl-tolyl-carbinol

NMe₂, C₆H₄Me C(OH)(C₆H₄NMe₂)(C₆H₄NMeH) The chloride NMe₂, C₆H₄Me C $\begin{array}{c} \text{C}_6\text{H}_4\text{NHMe} \\ | \\ \text{C}_6\text{H}_4\text{NHMe} \end{array}$ Cl

is probably the chief constituent of Hofmann's violet obtained by heating rosaniline with MeCl It has a green lustre and forms a violet solution in water The solution is decolourised by zinc dust HCl turns the solution first green, then yellow NaOH gives a brownish-red pp Conc H₂SO₄ gives a brownish-yellow solution changed, on dilution, through green to blue It dyes wool, silk, and mordanted cotton violet

Hexa-methyl-tri-amido-di-phenyl-tolyl carbinol NMe₂, C₆H₄Me C(OH)(C₆H₄NMe₂)₂ The zinc double salt of the methylo chloride of this body C₂₄H₂₄N₃Cl₂Zn or

NMe₂, C₆H₄Me C $\begin{array}{c} \text{C}_6\text{H}_4\text{NHMe} \\ | \\ \text{C}_6\text{H}_4\text{NHMe} \end{array}$ Cl appears to

constitute the dye known as 'iodine green,' which is obtained by heating rosaniline with MeCl, or by the action of MeCl on Hofmann's violet The

corresponding iodide $C_{12}H_{13}N_3I$, aq is obtained by heating MeI (2 pts) with MeOH (2 pts) and rosaniline (1 pt) at 100° (Hofmann a Girard, *B* 2, 440). The zinc double chloride forms a bluish-green aqueous solution, turned reddish yellow by hydrochloric acid, and rendered colourless by caustic soda. It dyes silk green. When heated strongly in the dry state it becomes violet. Its absorption-spectrum has been studied by Hartley (*C J* 51, 175). Iodine green may be reduced to penta methyl tri amido-di phenyl tolyl methane $NMe, C_6H_4Me, CH(C_6H_5, NMe_2)(C_6H_4, NHMe)$ [173°] (O Fischer a G Körner, *B* 16, 2910). Besides the bodies here described other methylated rosanilines are doubtless formed in the methylation of rosaniline.

DI-METHYL-AMIDO-PHENYL-p-TOLYL SULPHONE $C_{15}H_{17}NSO_2$ [95°] From $4[C_6H_4Me, SO_2, C_6H_4NMe_2]$ [95°] From C_6H_4Me, SO_2Cl and dimethylaniline (Michler a Meyer, *B* 12, 1793). Split up by HCl at 180° into MeCl, aniline, H_2SO_4 , and toluene. Zinc and H_2SO_4 reduce it to *p* tolyl mercaptan and dimethylaniline.

DI-METHYL-p-AMIDO-PHENYL-UREA $C_{12}H_{13}N_3O$ [179°] From potassium cyanate and di methyl-*p*-phenylene-diamine (Binder, *B* 12, 536). Long needles, sol hot water — $B''H_2PtCl_6$, yellow leaflets.

Tetra-methyl-di-*p* amido-di-phenyl-urea $C_{12}H_{13}N_3O$ [262°] (B), [246°] (M a Z). Obtained by heating urea with di-methyl *p* phenylene diamine (Binder, *B* 12, 535). The same body is apparently obtained by the action of COCl₂ on di methyl *p* phenylene diamine (Michler a Zimmermann, *B* 14, 2179) — $B''H_2Cl_2$, soluble crystalline powder — $B''H_2SO_4$, sl sol water — $B''H_2PtCl_6$.

METHYL- α -AMIDO-PROPANE SULPHONIC ACID $NHMe, CH_2, CHMe, SO_3H$ [220°-223°] From methyl propylene ψ -thio-urea and bromine-water (Gabriel, *B* 22, 2989). Colourless columns, v e sol water.

METHYL- α -AMIDO-PROPIONIC ACID $C_6H_5NO_2$ [260°] From α -chloro propionic ether and aqueous methylamine at 130° (Lundenburg, *J pr* [2] 12, 244). Prisms. Decomposed on fusion. Tastes sweet. Its copper salt crystallises in dark blue prisms — $HA'HCl$ [110°]. Deliquescent prisms $H_2A''H_2PtCl_6$, trichinic prisms — $HA'HNO_3$, [126°]. Monoclinic prisms.

Di-methyl α -amido-propionic acid *Methylochloride* $CH_3, CH(NMe_2, Cl), CO_2H$ Formed by treating α -chloro propionic ether with trimethylamine, saponifying the resulting ether with baryta, and adding HCl (Brühl, *B* 9, 34). Very hygroscopic, forming $(C_6H_5, NO_2, Cl)_2PtCl_6$ crystallising in roseate prisms, and $C_6H_5, NO_2, AuCl$, crystallising in golden needles. The corresponding *Anhydride* of the *Methylo-hydroxide* $CH_3, CH \begin{smallmatrix} CO \\ NMe_2 \end{smallmatrix} O$ or 'betaine' is formed on adding baryta to the methylo-chloride and subsequently neutralising with H_2SO_4 . It forms extremely deliquescent crystals, and is neutral in reaction. The iodide $(C_6H_5, NO_2)_2HI$ forms long colourless prisms, v sol alcohol and hot water.

DI-METHYL-AMIDO-PROPYL ALCOHOL v. DI-METHYL OXY-PROPYL AMINE

Tetra-methyl- β -di-amido-isopropyl alcohol C_6H_5, N_3O [170°-185°] Formed from di-chloro-isopropyl alcohol (*s* di-chlorohydrin) and NMe_2H at 60° (Berend, *B* 17, 510). Liquid, v e sol water — $B''H_2PtCl_6$; yellow plates.

Benzoyl derivative $(NMe_2, CH_2)_2CH, OBz$. Forms a platino chloride $B''H_2PtCl_6$, crystallising in tables.

DI-METHYL-AMIDO-PROPYLENE GLYCOL $C_6H_5, NO_2, NMe_2, CH_2, CH(OH), CH_2, OH$ [217°] From dimethylamine and chloro propylene glycol (chlorohydrin) (Roth, *B* 15, 1153). Thick syrup, v e sol water, alcohol, and ether — $B''H_2PtCl_6$.

Methylo-chloride $NMe_2, Cl, CH_2, CH(OH), CH_2, OH$ From the chlorohydrin and NMe_2 at 100° (V Meyer, *B* 2, 186; Hanriot, *A Ch* [5] 17, 99). Needles, v e sol water — $(C_6H_5, NO_2, Cl)_2PtCl_6$, crystalline tables — $C_6H_5, NO_2, AuCl$, [190°] Orange crystals, m sol alcohol.

Di-benzoyl derivative $NMe_2, CH_2, CH(OBz), CH_2, OBz$ oil — Picrate $B''O_2H, (NO_2)_2, OH$ [100°] Laminæ (Roth, *B* 15, 1153).

DI-METHYL-(B 2)-AMIDO-QUINOLINE $NMe_2, C_6H_4, CH, C, CH, CH$ [56°] $C_6H_5, (NMe_2), N$ [56°] CH, CH, C, N, CH

(C), [58°] (O) (e 335°) Prepared by boiling a mixture of *u*-di methyl *p* phenylene diamine (25 pts), glycerine (60 pts), nitro-benzene (15 pts), and H_2SO_4 (50 pts) (La Coste, *B* 16, 672). Colourless crystals. V sol alcohol, ether, and benzene.

Picrate $B''(C_6H_5, NO_2)_2, OH$ very fine orange needles [215°].

Methylo iodide $B'MeI$ long red needles — $(BMeCl)_2PtCl_6$.

Methylo-chloride $B'MeCl$ [244°] Long scarlet hygroscopic needles (Ostermayer, *B* 18, 596).

Methylo chloride of the tetrahydride $NMe, C_6H_5, NMeCl$ [220°], fine colourless needles. With ICl it forms $NMe, C_6H_5, NMeCl, ICl$ [127°], separating in small yellow crystals (Ostermayer, *B* 18, 596).

TETRA-METHYL-DI-AMIDO-QUINONE $C_6H_5, (NMe_2)_2, O_2$ [174°] Red tables. Formed by dissolving ordinary quinone in aqueous dimethylamine (Mylus, *B* 18, 467).

DI-METHYL-AMIDO-SULPHO-BENZOIC ACID $C_6H_5, (NMe_2)_2, (SO_3H), CO_2H$ [4 2 1] Obtained by heating the silver salt of amido sulpho benzoic acid with MeI and MeOH at 100° (Hedrick, *Am* 9, 413). Easily soluble crystals — CaA'' — $BaEt_2A''$.

TETRA-METHYL-DI-AMIDO-THIOBENZO-PHENONE C_6H_5, N_3, S [194°] (B), [202°] (G) S (alcohol) 072 at 18° S (ether) 27 at 18° S (chloroform) 4 53 at 18° . Formed by passing H_2S into an alcoholic solution of the hydrochloride of tetra methyl di-amido benzophenone imide (auramine) at 60° (Fehrmann, *B* 20, 2857; Baither, *B* 20, 1731, 3289). Formed also by the action of CS_2 on auramine (Graebe, *B* 20, 3266). Obtained also from $CSCl_2$ and dimethylaniline. Ruby red crystals, with blue lustre. Insol water and light petroleum, sl sol other solvents. Its

solutions in benzene and CS_2 are dark red with green fluorescence

Reactions — 1 Hot dilute hydrochloric acid gives H_2S and tetra-methyl di amido benzophenone — 2 Water at 120° under pressure also forms $\text{CO}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ — 3 Boiling concentrated nitric acid forms $\text{CO}(\text{C}_6\text{H}_3(\text{NO}_2)_2\text{NMeNO}_2)_2$, whence hydroxylamine hydrochloride forms $\text{CO}(\text{C}_6\text{H}_3(\text{NO}_2)_2\text{NMeH})_2$ [c 196°] — 4 By heating with excess of benzyl chloride it is converted into $\text{CO}_2(\text{C}_6\text{H}_4\text{NMe}_2)_2$, a greyish green powder, decomposed by water with production of $\text{CO}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ — 5 Aniline hydrochloride at 160° forms phenyl auramine $\text{NPh C}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ [171°] — 6 Phenylhydrazine at 100° forms $\text{CO}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ Aniline at 150° also forms this ketone — 7 Hydroxylamine gives the oxim of tetra methyl di amido benzophenone — 8 Distillation over red hot zinc dust yields di methyl aniline and tetra methyl-di amido di phenyl methane — 9 Acetyl chloride in the CS_2 solution forms $\text{C}_{11}\text{H}_{22}\text{N}_4\text{SACl}$, which forms a red alcoholic solution and a greenish yellow solution in benzene It begins to decompose at 160° — 10 Benzoyl chloride in CS_2 forms a similar compound $\text{C}_{11}\text{H}_{22}\text{N}_4\text{SBzCl}$, which is insol water, but decomposed by solution in alcohol — 11 Boiling with Ac_2O and NaOAc forms $\text{C}_{11}\text{H}_{22}\text{N}_4\text{SO}_4$, a dark grey powder — 12 Methyl iodide appears to give $\text{C}_{11}\text{H}_{22}\text{N}_4\text{SMel}$, which forms green plates with coppery lustre, decomposes at 108° , and yields a deep bluish green aqueous solution with red fluorescence It dyes silk green — 13 CSCl_2 acting on its CS_2 solution forms a black powder, probably $\text{C}_{11}\text{H}_{22}\text{N}_4\text{SCSCL}_2$. In chloroform solution, CSCL_2 forms white crusts of $\text{CCl}_2(\text{C}_6\text{H}_4\text{NMe}_2)_2\text{CHCl}$

METHYL-AMIDO-THYMOQUINONE

$\text{C}_{11}\text{H}_{17}\text{NO}_2$, $\pm \text{C}_6\text{H}_5\text{C}_6\text{HMe}(\text{NHMe})\text{O}_2$ [74°] From methylamine and thymoquinone in alcoholic solution (Zincke, B 14, 97) Dark violet laminae (from very dilute alcohol) Volatile with steam M sol water, v e sol alcohol The solutions are deep violet Alcoholic HCl converts it into methylamine and oxythymoquinone

Di methyl amido thymoquinone $\text{C}_{12}\text{H}_{19}\text{NO}_2$, $\pm \text{C}_6\text{H}_5\text{C}_6\text{HMe}(\text{NMe}_2)\text{O}_2$ Prepared by mixing dimethylamine with thymoquinone in alcoholic solution (Schulz, B 16, 899) Dark coloured oil Volatile with steam Split up by heating with dilute HCl into oxythymoquinone and di methylamine

Di methyl di-amido-thymoquinone

$\text{C}_{12}\text{H}_{19}\text{N}_2\text{O}_2$, $\pm \text{C}_6\text{H}_5\text{C}_6\text{HMe}(\text{NHMe})_2\text{O}_2$ [203°] Formed, together with methyl amido thymoquinone, by treating a cold concentrated alcoholic solution of thymoquinone with methylamine (Zincke) Formed also by the action of methylamine on di bromo thymoquinone Long reddish violet needles (from alcohol) Decomposed by KOH or H_2SO_4 in alcoholic solution into methylamine and di oxy thymoquinone

METHYL-AMIDO-TOLUENE v METHYL-TOLUIDINE

Methyl-di-amido-toluene v. METHYL-TOLYL-DIAMINE

Methyl-tri-amido-toluene $\text{C}_{11}\text{H}_{17}\text{N}_3$, $\pm \text{C}_6\text{H}_4\text{Me}(\text{NHMe})_3(\text{NHMe})$ The hydrochloride $\text{B}^+\text{H}_2\text{Cl}_2\text{aq}$ is prepared by reducing the nitramine of di-nitro-methyl-o-toluidine with tin and

HCl (Van Romburgh, R T C 3, 400) It forms small crystals

Di-methyl-amido-toluene sulphonic acid $\text{C}_6\text{H}_4\text{N}_2\text{SO}_3$, $\pm \text{C}_6\text{H}_4\text{MeSO}_3\text{H}$ [214°] Formed by heating di methyl-o toluidine (1 pt) with H_2SO_4 (4 pts) at 180° to 210° (Michler & Sampaio, B 14, 2168) Large glittering prisms (from water), insol alcohol, v sol hot water — CaA'_2 (dried at 130°) Nodules — BaA'_2 (dried at 130°) Laminæ, v sol hot water — ZnA'_2 , needles

TETRA METHYL-DI AMIDO-DITOLYL

$\text{NMe}_2\text{C}_6\text{H}_4\text{MeC}_6\text{H}_4\text{MeNMe}_2$ Tetra - methyl-toluidine [80°] Formed by oxidising di methyl-o toluidine with MnO_2 and dilute H_2SO_4 Formed also by methylation of di amido ditolyl (Michler & Sampaio, B 14, 2170) White plates, sol ether and hot alcohol, insol water — $\text{B}^+\text{H}_2\text{Cl}_2$ white needles — $\text{B}^+\text{H}_2\text{PtCl}_4$ yellow crystalline pp

Tetra methyl di amido-ditolyl $\text{C}_{18}\text{H}_{22}\text{N}_4$, $\pm \text{NMe}_2\text{C}_6\text{H}_4\text{MeC}_6\text{H}_4\text{MeNMe}_2$ [190°] Formed in small quantity by heating dimethyl o-toluidine with H_2SO_4 (M & S) Long needles, sol hot alcohol, ligroin, and ether, insol water Gives a green colouration with Fe_2Cl_6 and yellow colour with CrO_3

Tetra-methyl-di-amido-ditolyl (?) $\text{C}_{18}\text{H}_{22}\text{N}_4$, $\pm \text{NMe}_2\text{C}_6\text{H}_4\text{MeC}_6\text{H}_4\text{MeNMe}_2$ [57°] Prepared by heating dimethyl p toluidine with H_2SO_4 (Michler & Pattinson, B 14, 2167) White needles, sol alcohol and ether, insol water — $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_4$

DI - METHYL - AMIDO - TOLYL - BUTANE

$\text{C}_{11}\text{H}_{17}\text{N}$, $\pm \text{C}_6\text{H}_5\text{C}_6\text{HMeNMe}_2$ [251°] From amido tolyl butane and MeI (Effront, B 17, 2339) — $\text{B}^+\text{H}_2\text{PtCl}_4$

DI - METHYL AMIDO - TOLYL METHYL

KETONE $\text{C}_{11}\text{H}_{17}\text{NO}$, $\pm \text{C}_6\text{H}_5\text{C}_6\text{H}_2(\text{CH}_3)(\text{NHMe})\text{COCH}_3$ [95°] Flat yellowish prisms, e sol alcohol, ether, and hot water, nearly insol petroleum ether Formed by methylation of amido tolyl methyl ketone (Khngel, B 18, 2699)

METHYL α AMIDO α VALERIC ACID

$\text{C}_6\text{H}_9\text{NO}_2$, $\pm \text{CH}_3\text{CH}_2\text{CH}_2\text{CH}(\text{NHMe})\text{COH}$ Obtained by heating butyric aldehyde with conc aqueous HCl, adding methylamine, and heating again The nitrile then separates as an oil, which is hydrolysed by prolonged boiling with dilute HClAq (Menozzi & Belloni, G 17, 116) Long glistening needles (containing aq), decomposed partially at 110° with formation of a sublimate

Salts — $\text{CuA}'_2\text{aq}$ blue prisms — $\text{HA}'\text{HNO}_3$, prisms, v sol water

Methyl α -amido isovaleric acid $\text{C}_6\text{H}_9\text{NO}_2$, $\pm (\text{CH}_3)_2\text{CHCH}(\text{NHMe})\text{CO}_2\text{H}$ Formed by boiling α bromo isovaleric acid with aqueous methylamine (Duvillier, C R 88, 425, A Ch [5] 21, 434) White crystalline powder, v e sol water, m sol hot alcohol, insol ether Neutral in reaction With cyanamide it forms a creatinin $\text{C}_6\text{H}_9\text{N}_3\text{O}$, crystallising in slender needles, v. sol boiling alcohol (Duvillier, C R 95, 456) — $\text{HA}'\text{HCl}$ Crystallises with difficulty — $\text{H}_2\text{A}'\text{H}_2\text{SO}_4$ prisms, v sol water — $\text{HA}'\text{HAuCl}_4\text{aq}$ short trimetric prisms The copper salt forms an intense blue solution

Di - methyl - α - amido - isovaleric acid. Methyl-o-tolide of the methyl ether.

Fr OH(NMe₂I) CO₂Me. Formed by heating MeI (4 pts) with zinc amido-valerate (1 pt) and ZnO (1 pt) at 110° for 16 hrs (Duvillier, *C R* 110, 640). Yields [Fr OH(NMe₂Cl) CO₂H], PtCl₄aq and Fr.OH(NMe₂Cl) CO₂HauCl.

METHYLAMINE ONH, $\frac{1}{2}$ CH₃NH₂. Mol w 81 (−6°) (Hofmann, *B* 22, 701) S G −103.699 H F p 9,540 H F v 8,880 (Thomsen, *Th*) H C 256,900 (Müller, *Bl* [2] 44, 609) Heat of neutralisation by HCl 25,900 (Müller, *A Ch* [6] 15, 531) S (gas) 1150 at 12.5°, 950 at 25°

Occurrence—1 In bone oil (Anderson, *B* 80, 44)—2 In *Mercurialis annua* and *M. perennis* (Schmidt, *B* 10, 2226, *A* 193, 73, cf Reichardt, *Z* 1868, 734)—3 In herring bone (Bookhisch, *B* 18, 1922)—4 In crude wood spirit (G Williams, *Chem Gas* 1853, 409, Commaile, *J* 1873, 686, Vincent, *C R* 77, 898)—5 In the product of the distillation of beet root molasses (Duvillier a Buisne, *A Ch* [5] 23, 317)—6 In the 'yolk' or 'sunt' of sheep When an aqueous extract of this substance is allowed to stand for some time, and is then boiled, it gives off 4 pts of NH₂Me for 95 pts of NH₃, and 1 pt of NMe₂ (Buisne, *C R* 104, 1292)

Formation—1 Discovered by Wurtz, who obtained it by distilling methyl cyanate (or cyanurate) with potash (*C R* 28, 223, 323, *A Ch* [3] 30, 443)—2 By decomposing methylurea with potash (Wurtz)—3 In small quantity, together with NMe₂, and NMe₃, by heating ammonia with MeI (Hofmann, *A* 79, 19) Formed also by heating the methyl ethers of other inorganic acids with ammonia—4 By heating wood spirit with ammonium chloride or iodide at 300° (Berthelot, *J* 1852, 551, Girard, *Bl* [2] 24, 121, cf Weith, *B* 8, 458) By heating methyl alcohol (3 pts) with NH₄Cl (2 pts) and HCl (1 pt) at 207° for 30 hours Dusart a Bardy converted one third of the NH₃ into NH₂Me (*C R* 74, 188).—5 By heating methyl alcohol with ammoniacal ZnCl₂ (Gasiorski, *B* 17, 639)—6 By heating morphine or codeine with KOH (Wertheim, *A* 73, 210, Anderson, *A* 77, 874)—7 By distilling glycochol with BaO (Cahours, *A* 109, 28)—8 By the action of chlorine on theobromine or caffeine (Rochleder a Hlasiwetz, *J* 1850, 434, 437)—9 In small quantity by reducing HCl with zinc and dilute H₂SO₄ (Mendius, *A* 121, 129)—10 By passing a mixture of HCl and hydrogen over platinum-black at 110° (Debus, *A* 128, 200)—11 By reducing nitro methane with iron filings and dilute HOAc (Freibisch, *J pr* [2] 7, 480)—12 By digesting di methyl urea acid with HClAq for several hours at 170° (Hill a Mabery, *Am* 2, 310)

Preparation—1 By distilling methyl cyanurate with aqueous KOH (Wurtz) The distillate is received in dilute HCl, and the methylamine hydrochloride dried and distilled with quicklime 2 A mixture of acetamide (1 mol) and bromine (1 mol) is treated in the cold with a 10 p c solution of KOH till nearly decolourised The solution of methyl-bromo-amide thus obtained is then run in a slow stream into a 30 p c solution of 8 mols of KOH heated to 60°–70° and digested for 10 or 15 mins till decolourised. The solution is then boiled and the methylamine received in HCl, the yield is 87 p c of the theoretical (Hofmann, *B* 15, 765, 18, 2741).—

3 Methyl nitrate (1 mol) is heated in closed vessels at 100° with a solution of ammonia (1 mol) in wood spirit Besides the nitrate of mono methyl-amine there is formed tetra methyl ammonium nitrate together with small quantities of di- and tri methylamine nitrates At the end of the reaction the product is neutralised with sulphuric acid, heated to evaporate off the alcohol, and the residue decomposed by potash, and the bases received in hydrochloric acid The hydrochlorides are treated with absolute alcohol to remove the ammonium chloride, and again decomposed, the bases being received in sulphuric acid The sulphates are then treated with absolute alcohol in which mono methyl amine sulphate is insoluble To remove the last traces of impurities the insoluble sulphate is again decomposed and converted into di methyl oxamide, which yields on decomposition pure mono-methyl amine (Duvillier a Buisne, *A Ch* [5] 23, 322, cf Juncadella, *C R* 48, 342)—4 By the action of tin and HCl on chloropierin (Wallach, *A* 184, 51, cf Geisse, *A* 109, 282)—5 By heating dry ammonium methyl sulphate at 300° and distilling the product with potash (Milner Morrison, *Pr E* 10, 275)

Properties—Colourless gas with strong ammoniacal odour Not solid at −75° Turns red litmus blue Fumes strongly with HCl Rapidly absorbed by water and by charcoal Of all known gases it is the most soluble in water Burns in air with livid yellowish flame (difference from NH₃) The aqueous solution of methylamine is extremely caustic, and gives off the gas when boiled It ppts metallic salts, for the most part in the same manner as ammonia Zinc hydroxide is, however, soluble in a large excess of methylamine With cupric salts it gives a bluish-white pp dissolving in excess and forming a deep blue solution With salts of Cd, Ni, and Co it forms pps insoluble in excess (difference from NH₃) It ppts lead nitrate but not lead acetate With mercurous nitrate it gives a black pp, with HgCl₂ a white pp, with AgNO₃ it gives a pp of Ag₂O soluble in excess It dissolves AgCl With chloride of gold it gives a brownish yellow pp, soluble in excess Platinic chloride gives a yellow crystalline pp

Reactions—1 Passage through a red-hot tube converts it into hydrogen, CH₄, ammonia, and HCl No acetylene, benzene, or C₂H₂ is formed (Müller, *Bl* [2] 45, 438) When an aqueous solution of methylamine is set on fire, HCl is found in the residue (Tollens, *Z* [2] 2, 516)—2 Heated potassium forms hydrogen and KCy—3 Cyanogen chloride forms methyl cyanamide (Cahours a Cloëz, *C R* 38, 354)—4 Iodine forms MeNI₂—5 CO₂ forms methylamine methyl-carbamate—6 According to Berthelot, heating with saturated HIAq yields ammonia and CH₄—7 COCl₂ yields NHMe COCl (90°)—8 Liquid MeCl under pressure, forms NMe₂Cl and NMe₂H₂Cl (Vincent a Chappuis, *C R* 102, 436)—9 MeBr (1 mol) in MeOH at 100° forms, chiefly, NMe₂Br In like manner MeI forms NMe₂I (Duvillier a Buisne, *C R* 90, 1426)—10 Benzene aldehyde added to aqueous NMe₂H, forms PhOH NMe₂, an oil (c 180°) which yields benzyl-methylamine (185°) on reduction (Zaun-schirm, *A* 245, 281).—11 o-Oxy benzoic aldehyde forms C₆H₅NO (229°) (Dennstedt a Zimmer-

mann, *B* 21, 1553) —12 'Dicyanamidobenzoyl' (cf vol 1 p 155) forms small needles of $C_6H_4N_4O$ (Griss, *B* 18, 2420) —13 *Diazo-benzene chloride* added to a cool 33 p.c. solution of methylamine forms $MeN(N_2Ph)_2$ [118°] which crystallises in yellow needles, v sol. ether, m sol. alcohol. It is reduced by Zn and $HOAc$ to methylamine and phenylhydrazine. Boiling dilute H_2SO_4 gives nitrogen, aniline, $MeOH$, phenol, and some $PhN_2C_6H_5NH_2$ (Goldschmidt & Badl, *B* 22, 934) —14 *o* *Diazo-anisole chloride* forms yellow needles of the compound $MeN(N_2C_6H_4OMe)_2$ [141°] (G & B) —15 *p* *Diazo-anisole chloride* forms $MeN(N_2C_6H_4OMe)_2$ [112°] (G & B) —16 *p* *Diazo-toluene chloride* forms $MeN(N_2C_6H_4Me)_2$ [147°]

Salts — $BHCl$. Large deliquescent laminae (from water), may be sublimed. Sol. alcohol, m sol. $CHCl_3$ — $B^+HAuCl_4^-$ aq. Trimetric crystals (Topsoe, *J* 1883, 618) — $B^+HAuCl_4^-$ Monoclinic (T) — $B^+H_2PtCl_6^-$ Golden hexagonal scales (Ludecke, *J* 1890, 511) S 2 at 14° Insol. alcohol, not decomposed by boiling water (De Coninck, *Bl* [2] 45, 131) — $B^+H_2Cl_2PtBr_2^-$ Scarlet crystals (Maly & Hinterberger, *M* 3, 89) — $B^+PtCl_6^-$ Insoluble green powder — $B^+PtCl_6^-$ V e sol. water — $B^+H_2IrCl_6^-$ Small hexagonal brownish black plates (Vincent, *Bl* [2] 43, 154) — $B^+H_2RhCl_6^-$ (Vincent, *C* R 101, 322) — $B^+H_2HgCl_6^-$ Monoclinic crystals, v sol. water — $B^+HHgCl_6^-$ Rhombohedral crystals (T) — $B^+H_2CuCl_6^-$ Trimetric crystals — $B^+H_2PdCl_6^-$ B^+HBr Large deliquescent plates (from alcohol), v sol. water and alcohol — B^+HI — $B^+H_2I_3BiI_4^-$ Scarlet pp (Kraut, *A* 210, 312) — $B^+H_2I_3BiI_4^-$ Crystalline pp (K) — B^+HNO_3 Elongated trimetric prisms. Deliquescent, v sol. water, sl sol. cold alcohol [100°] (Franchimont, *R T C* 2, 338) — $B^+H_2SO_4$ Deliquescent needles, insol. alcohol — B^+HMeSO_4 Crystals, v e sol. water (Classon & Lundvall, *B* 13, 1701) — B^+HVO_4 (Bailey, *C* J 45, 692) — B^+HVO_4 aq. Colourless acicular crystals (Ditte, *C* R 104, 1844) — $B^+(H_2O)(V_2O_5)_4$ aq. Yellow powder (D) — $B^+(H_2O)(V_2O_5)_3$ aq. (B) — $B^+H_2CO_3$ Formed, together with methyl carbamic acid $NMeHCO_2H$, by decomposing $CaCO_3$ with methylamine hydrochloride. Deposited in crystals from the liquid distillate — $B^+H_2C_2O_4$ Prisms, v sol. water, insol. alcohol —Benzene sulphonate [147°] (Norton & Westenhoff, *Am* 10, 129) —Valerate $NH_2Me_2CO_2MeCO_2H$? [81°] (175°) From NH_2Me and tri methyl-acetic acid at 150° (Franchimont & Klobbie, *R T C* 6, 234)

Acetyl derivative C_2H_5NO s. $NMeAcH$ *Methyl acetamide* [28°]. (206°) From $EtOAc$ and aqueous methylamine at 150° (Hofmann, *B* 14, 2725) — $NMeAcHNH_2$ [58°] Large hygroscopic crystals (Franchimont, *R T C* 2, 341)

Di-acetyl derivative $C_4H_8NO_4$ s. $NMeAc_2$ (192°) A product of the action of Ac_2O on methyl-acetyl urea (H.) Liquid, miscible with water. Split up by HCl into methylamine and acetic acid

Tri-chloro-acetyl derivative $CCl_3CO NMeH$ [106°] From CCl_3CO_2Et and aqueous methylamine (Franchimont & Klobbie, *R T C* 6, 234) White crystals, sl sol. water and ether. Slowly attacked by pure HNO_3 , which gives off N_2O

Valeryl derivative $CMe_3CO NMeH$ [91°] (204°) VD 398 From Me_3CCOCl and NH_2Me Methylamine and Me_3CCO_2Me yield only (Me_3CCO_2H), NH_2Me V sol. water and alcohol (F & K.) Pure HNO_3 gives off N_2O

Heptyl derivative $C_7H_{15}CO NMeH$ [9°] (266°) SG 13 895 Thick liquid (F & K)

Benzoyl derivative $C_6H_5CO NMeH$ [78°] Crystallises from alcohol (Romburg, *R T C* 4, 388)

o-Amido benzoyl derivative $C_6H_4(NH_2)CO NMeH$ [80°] From isatoic acid and methylamine solution (Weddige, *J* pr [2] 36, 150) Thick prisms (from benzene), v e sol. alcohol and ether, sol. hot water. Ac_2O gives $C_6H_4(NHAc)CO NMeH$ [172°] $BzCl$ forms $C_6H_4(NHbz)CO NMeH$ [181°] (Körner, *J* pr [2] 36, 159)

Other alkoyl derivatives are described under the acids from which they are derived

Methyl-di-chloro-amine CH_2NCl_2 (60° uncor.) Pungent yellow liquid (Köhler, *B* 12, 770)

Methyl-di-bromo-amine CH_2NBr_2 Formed by the action of bromine and potash on methylamine hydrochloride (Hofmann, *B* 15, 767) Extremely pungent liquid. Slowly converted into methylamine by HCl

Methyl-di-iodo-amine CH_2NI_2 Formed by the action of iodine on aqueous methylamine (Wurtz, *A Ch* [3] 30, 455) Prepared by adding iodine (1g) and water (50g) to methylamine hydrochloride, and then adding aqueous $NaOH$ (Raschig, *A* 230, 221) Brownish red pp., quickly becoming brick red. Completely soluble in aqueous HCl , soon decomposing into methylamine and ICl . Ammonia forms $NMeH$ and NH_3 . Cold potash dissolves it, forming methylamine, KIO_3 , and KI

Methyl nitro-amine CH_2NHNO_2 [38°] Obtained by treating methyl chloroformate with methylamine, nitrating the resulting methyl methyl-carbamate CH_2NHCO_2Me , and boiling the product with ammonia (Franchimont & Klobbie, *R T C* 7, 354, 8, 297) Formed also by decomposing NO_2 , $NMeCOCO_2NMeNO_2$, with aqueous ammonia. Colourless needles, sol. alcohol. Strongly acid in reaction. Converted by KOH and MeI into crystalline Me_2NNO_2 — $KMeNNO_2$. Slender needles, sol. alcohol and water

Dimethylamine C_2H_5N s. $(CH_3)_2NH$ Mol w 45 (72°) (Hofmann, *B* 22, 702) SG -33 687 SV 152 4 (Ramsay) HFp 12,720 (Thomson), 3,500 (Muller, *Bl* [2] 44, 609) HFv 10,980 (Thomson, *Th*) HC 42,600 (M.) *Heat of neutralisation* (by HCl) 23,980 (Müller, *A Ch* [6] 15, 531)

Occurrence —In herring-brine (Bookisch, *B* 18, 1924)

Formation —1 One of the products of the action of MeI on ammonia (Hofmann) —2 A mixture of mono-, di-, and tri methylamine is obtained by heating methyl alcohol with ammoniacal $ZnCl_2$ at 200°–220° (Menz & Gasiorowski, *B* 17, 639) —3 In small quantity by heating the sulphite of aldehyde ammonia in a sealed tube, or by distilling it with lime (Petersen, *A* 102, 317)

Preparation—1 The mixture of iodides obtained by heating ammonia with MeI is distilled with potash, and the evolved bases dried by KOH and condensed by a freezing mixture, the bases NMe_2 , NMe_2H , and NMe_2H_2 being separated by means of oxalic ether (Hofmann, *Pr* 12, 380)—2 The bases obtained from MeBr and NH_3 are treated with nitrous acid, and the dimethylnitrosamine decomposed by HCl and distilled over sodium (Hofmann)—3 Nitroso-dimethylaniline hydrochloride (2 pts) is boiled with water (90 pts) and aqueous NaOH (10 pts of S G 125) (Baeyer & Caro, *B* 7, 964, 8, 616).

Properties—Highly alkaline liquid or gas. Has not been solidified. If to an alcoholic solution of the base picryl chloride $\text{C}_6\text{H}_2(\text{NO}_2)_3\text{Cl}$ be added, and then H_2SO_4 followed by water, there is formed a characteristic yellow pp of tri nitro-dimethyl-aniline (Van Romburgh, *R T C* 2, 106).

Reactions—1 MeCl forms only NMe_2Cl and NMe_2HCl (Vincent & Chappuis, *C R* 102, 436)—2 SO_2Cl_2 forms only $\text{NMe}_2\text{SO}_2\text{Cl}$ (183° — 187°) and $\text{SO}_2(\text{NMe}_2)_2$ (Behrend, *B* 14, 1810)—3 Cyanamide heated with NHMe_2 at 110° forms di-methyl guanidine (Tatarinoff, *C R* 89, 608) 4 *p*-Diazotoluene chloride forms $\text{NMe}_2\text{N}_2\text{O}_2\text{H}$, [46°] (Goldschmidt & Badl, *B* 22, 935).

Salts— B^+HCl V sol chloroform (differ from NH_4Cl and NMe_2HCl (Behrend, *B* 15, 1611, *A* 222, 119)— $\text{B}^+\text{H}_2\text{AuCl}$, Monoclinic needles— $\text{B}^+\text{H}_2\text{PtCl}_2$, Trimeric needles— $\text{B}^+\text{H}_2\text{IrCl}_4$, Trimeric octahedra, *abc* = 1.969 1.1954 (Vincent, *Bl* [2] 43, 154)— $\text{B}^+\text{Rh}_2\text{Cl}_3$, 8aq Large dark garnet red prisms (Vincent, *Bl* [2] 44, 513, *C R* 101, 322)— $\text{B}^+\text{H}_2\text{HgCl}_2$, Monoclinic crystals (Topsoe, *J* 1883, 618)— $\text{B}^+\text{THg}_2\text{Cl}_2$, Monoclinic crystals (*T*)— $\text{B}^+\text{H}_2\text{Hg}_2\text{Cl}_2$, Triclinic crystals— $\text{B}^+\text{H}_2\text{SnCl}_4$, Trimeric tables (Hjortdahl, *J* 1882, 474)— $\text{B}^+\text{H}_2\text{CuCl}_2$ — $\text{B}^+\text{H}_2\text{CuCl}$, Crystals— $\text{B}^+\text{HClCuCl}$, Monoclinic crystals (*T*)— B^+HBr — $\text{B}^+\text{H}_2\text{PbBr}$, Trimeric needles— $\text{B}^+\text{H}_2\text{I}_2\text{BiI}_4$ — $\text{B}^+\text{H}_2\text{I}_2\text{BiI}_4$ (Kraut, *A* 210, 314)— B^+HNO_2 , [74°] Long hygroscopic needles or prisms V sol alcohol (Franchimont, *R T C* 2, 338, 3, 229) Decomposed by heat, yielding nitrogen, CO_2 , and dimethylamine (Romburgh, *R T C* 5, 246)— B^+HVO , (Bailey, *C J* 45, 693)— $\text{B}^+(\text{H}_2\text{O})_2(\text{V}_2\text{O}_5)_2$, 4aq—Benzene sulphionate [110°] (Norton, *Am* 10, 129)—*p*-Toluene sulphionate [78°] (*N*)

Acetyl derivative NMe_2Ac (166°) S G 22 941 From dimethylamine and AcCl dissolved in ether (Franchimont, *R T C* 2, 121, 342) Colourless liquid Fuming HNO_3 forms in the cold NMe_2NO , [57°]

Tri-chloro-acetyl derivative $\text{CCl}_3\text{CO NMe}_2$, [104°] (*C*) S G 12 1441 (*F* & *K*) From $\text{CCl}_3\text{CO CCl}_3$ and NMe_2 (Closz, *A Ch* [6] 9, 145)

Heptyl derivative $\text{C}_7\text{H}_{15}\text{CO NMe}_2$, (248°) S G 12 894 Solidifies below -10° (Franchimont & Klobbie, *R T C* 6, 249) With HNO_3 it gives di-methyl-nitro-amine

Valeryl derivative $\text{CMe}_2\text{CO NMe}_2$, (185°) S G 12 912 Liquid, v sol water Not solidified at -17° HNO_3 (S G 152) forms NMe_2NO .

Benzoyl derivative $\text{C}_6\text{H}_5\text{CO NMe}_2$, [42°] (256° uncor.) Crystals, v sol water Split up by aqueous HCl at 200° into HOBz and

HNMe_2 (Hallmann, *B* 9, 846) Conc HNO_3 gives $\text{C}_6\text{H}_5(\text{NO}_2)\text{CO NMe}_2$ (Romburgh, *R T C* 4, 385) With COCl_2 it forms deliquescent crystals of $\text{C}_6\text{H}_5\text{CCl}_2\text{NMe}_2$, [36°] decomposed by water into HCl and $\text{C}_6\text{H}_5\text{CO NMe}_2$.

Di-methyl-iodo-amine NMe_2I From dimethylamine, iodine, and NaOH Pale yellow pp, which rapidly decomposes (Raschig, *A* 230, 223)

Dimethylnitrosamine NMe_2NO (148° at 725 mm) Formed by treating an aqueous solution of dimethylamine hydrochloride with potassium nitrite (E Fischer, *B* 8, 1587, Renout, *B* 13, 2169) Yellow oil Volatile with steam Reduced by zinc dust and HOAc to di methyl hydrazine Decomposed by boiling HCl into NMe_2H and nitrous acid— B^+HCl white needles, decomposed by water or alcohol

Di-methyl nitro amine NMe_2NO_2 , [57°] From NMe_2Ac and HNO_3 (Franchimont) Large crystals

Di methyl amine tri-bromide Me_2NBr_3 , 2aq or $\text{Me}_2\text{N} \begin{matrix} \text{Br} \\ \text{H} \end{matrix} \begin{matrix} \text{Br} \\ \text{H} \end{matrix} \begin{matrix} \text{Br} \\ \text{H} \end{matrix} \begin{matrix} \text{OH} \end{matrix}$ Formed, as a yellow pp, on adding an excess of bromine water to a cold solution of dimethylamine— $2\text{Me}_2\text{NH} + 4\text{Br} + 2\text{H}_2\text{O} = \text{C}_2\text{H}_5\text{NBr}_3\text{O}_2 + \text{Me}_2\text{NH}_2\text{Br}$ Yellow powder Sol alcohol and ether, v sl sol water It is very unstable on keeping over night in a closed vessel it liquefies to a brown fluid containing free bromine, but under water it can be kept for several days Alkalis and acids decompose it at once, thus HCl gives dimethylamine hydrochloride according to the equation $\text{C}_2\text{H}_5\text{NBr}_3\text{O}_2 + 2\text{HCl} = \text{Me}_2\text{NH}_2\text{HCl} + 3\text{Br} + \text{Cl} + 2\text{H}_2\text{O}$ (Raschig, *B* 18, 2249)

Trimethylamine $\text{C}_3\text{H}_7\text{N}$ *see* NMe_3 , Mol w 59 (35°) S G 12 662 (Hofmann, *B* 22, 703) H F p 15,870 (Thomsen, *Th*), 14900 (Muller, *Bl*, [2] 44, 609) H F v 13550 H C 577,600 (*M*) Heat of neutralisation (by HCl) 17,900 (Muller, *A Ch* [6] 15, 531)

Occurrence—In herring brine (Hofmann, *C J* 5, 288, cf Wertheim, *J* 1851, 480) In the flowers of *Crataegus oxyacantha* (Wicke, *A* 91, 121), *C monogyna*, *Pyrus aucuparia*, and *P communis* (Wittstein, *J* 1854, 479) In the stinking goosefoot (*Chenopodium vulvaria*) (Dessaigues, *J* 1851, 481), in *Arnica montana* (Hesse, *J* 1864, 458), and in the seeds of the beech (Brandl & Rakowicki, *J* 1864, 607) It also occurs in *Mercurialis annua* (E Schmidt, *B* 10, 2226) In human urine (Dessaigues, *A* 100, 218), and in calves' blood which has stood 12 hours (Dessaigues, *J Ph* [3] 32, 43) In ergot of rye (Walz, *J* 1852, 552, Rithausen, *Rph chim pur* 1863, 420, cf Brieger, *H* 11, 184) In small quantity in guano (Hesse, *J* 1857, 402) In bone oil (Anderson, *A* 80, 51) According to Ludwig (*Z* 4, 96) it occurs in small quantity in several Austrian and Hungarian wines In the product of the destructive distillation of putrid brann (Selmi, *G* 6, 468) and of beet-root molasses (Vincent, *C R* 84, 1139, 85, 667, *J Ph* [4] 80, 132, Roscoe, *C N* 39, 107). In the putrefaction of yeast (*A Müller*, *J* 1857, 402) and of wheat dough (Sullivan, *J* 1858, 231). In most of the cases here mentioned the trimethylamine is probably obtained from betaine,

neurine, or lecithin, either by putrefactive decomposition or in the chemical treatment

Formation—1 Together with NMe_2H and NMe_2H by the action of ammonia on MeI , and separated by treatment with oxalic ether, with which it does not react (Hofmann, *C J* 4, 304) 2 By the distillation of NMe_2OH (Hofmann, *A* 93, 325)—3 By heating narcotine with KOH at 280° (Wertheim, *A* 73, 208)—4 By heating extract of calamus root with alkali (Thoms, *B* 21, 1912)—5 By passing coal gas through heated zinc dust (Williams, *C N* 51, 15)

Preparation—1 The residues in the preparation of sugar from beet root are, after fermentation, subjected to dry distillation. The aqueous portion of the distillate is neutralised by H_2SO_4 , ammonium sulphate separated by crystallisation, and, after evaporation, the trimethylamine expelled by an alkali. Commercial trimethylamine still contains methylamine, ethylamine, dimethylamine, propylamine, and isobutylamine. The proportion in which these bases are present varies greatly in different samples. To the aqueous solution of the bases oxalic ether is added, the primary bases being pptd as di alkyl oxamides. The mother liquor is distilled with addition of KOH and the dry bases dissolved in absolute alcohol. Oxalic ether is then added to the alcoholic solution, when the diamines are converted into di alkyl oxamic ethers, and the trimethylamine can be obtained by distillation (Vincent, *C R* 89, 238, 788, Duvillier a Buisine, *C R* 89, 48, 709, 92, 250, *A Ch* [5] 23, 298, cf. Eisenberg, *B* 13, 1669) 2 Perfectly pure trimethylamine is obtained by distilling NMe_2OH and rectifying over sodium (Hofmann, *B* 22, 699)

Properties—Gas with ammoniacal and fishy odour. Remains liquid at -75° . V e sol water. When an aqueous solution is strongly cooled a hydrate $\text{NMe}_2\cdot 7\text{aq}$ [4 3°] separates

Reactions—1 KMnO_4 oxidises it to CO_2 and oxalic acid (Wallach a Claisen, *B* 8, 1237)—2 At a red heat it is converted into HCy and NH_3 (Willm, *Bl* [2] 41, 449). Passed with hydrogen through a red-hot tube it yields NH_3 , cyanogen, hydrocarbons, and $\text{CH}_2(\text{NMe}_2)_2$ (Bo meny, *B* 11, 835)—3 CS_2 forms $\text{NMe}_2\cdot\text{CS}_2$, crystallising in white needles [125°]. This body is m sol chloroform and dilute alcohol, nearly insol absolute alcohol, CS_2 , and benzene. It splits up into its components, even at ordinary temperatures, but with dilute HCl it forms $\text{NMe}_2\cdot\text{CS}_2\cdot\text{HCl}$ and $(\text{NMe}_2\cdot\text{CS}_2)_2\cdot\text{H}_2\text{Cl}$. Conc HCl aq splits it up into its components. Phosphoric acid forms $(\text{NMe}_2\cdot\text{CS}_2)_2\cdot\text{H}_2\text{PO}_4$ (Bleunard, *C R* 87, 1040)—4 Glycol chlorhydrin forms neurine chloride $\text{NMe}_2\cdot\text{ClCH}_2\cdot\text{CH}_2\cdot\text{OH}$ —5 Chloroacetic acid forms betaine $\text{CH}_2\langle\text{NMe}_2\text{O}\rangle\text{CO}$ —

6 Dichlorhydrin of glycerin forms 'sepine' chloride $\text{C}_3\text{H}_7\text{Cl}(\text{OH})\text{NMe}_2\text{Cl}$ and 'aposepine' chloride $\text{C}_3\text{H}_7(\text{OH})(\text{NMe}_2)_2\text{Cl}$ (Niemi kovitoh, *M* 7, 249)—7. Hexa chloroacetone forms $\text{CCl}_3\cdot\text{CO}\cdot\text{NMe}_2$ [104°] (Closz, *A Ch* [6] 9, 145) 8 When heated with aniline hydrochloride it yields a distillate of methyl aniline

Salts— B^+HCl decomposes at 285° , giving off NMe_2 and MeCl , and leaving mono- and dimethylamine hydrochlorides. At 805° ammonia

and methyl chloride are given off from the residue, and at 325° the whole has sublimed, the sublimate consisting of NH_4Cl and methylamine hydrochloride. This decomposition may be utilised for the manufacture of MeCl (Vincent, *C R* 84, 1139, 85, 666)— B^+HBr decomposed between 230° and 300° into NMe_2 , ammonia, and MeBr — B^+HI white scales, decomposed between 210° and 280° into NMe_2 , ammonia, MeI , and a residue of NMe_2I — $\text{B}^+\text{H}_2\text{PtCl}_4$, orange regular crystals (Ludecke, *J* 1880, 512, Topsoe, *J* 1883, 618) S (alcohol) 0362 More soluble than the di- and still more so than the mono-methylamine platinumchloride (Eisenberg, *A* 205, 139)— $\text{B}^+\text{H}_2\text{IrCl}_4$, reddish brown octahedra (Vincent, *Bl* [2] 43, 155)— B^+HAuCl_4 , yellow monoclinic crystals. V al sol water, sol alcohol [220°] (Hesse, *J pr* 71, 480, Zay, *G* 13, 420)— $\text{B}^+\text{H}_2\text{Rh}_2\text{Cl}_4$, 9aq (Vincent, *C R* 101, 322)— B^+HCdCl_4 , trimetric crystals (Hjortdahl, *J* 1882, 475)— $\text{B}^+\text{H}_2\text{HgCl}_4$, monoclinic crystals (T)— B^+HHgCl_4 , monoclinic crystals (T)— $\text{B}^+\text{HHg}_2\text{Cl}_4$, triclinic crystals (T)— $\text{B}^+\text{HHg}_2\text{Cl}_4$, rhombohedra (T)— B^+HCuCl_4 , 2aq monoclinic crystals— B^+HCdBr_4 , six sided hexagonal prisms— $\text{B}^+\text{H PtBr}_4$ — $\text{B}^+\text{H}_2\text{I}_3\text{BiI}_4$ — $\text{B}^+\text{H}_2\text{I}_2\text{BiI}_4$, six-sided crimson plates (Kraut, *A* 210, 316)— B^+HNO_3 [153°] Long needles or prisms, v sol hot alcohol (Franchimont, *R T C* 2, 338)— $\text{B}^+\text{H}_2\text{SO}_4\cdot\text{Al}_2(\text{SO}_4)_3$, 24aq [100°] Large crystals (Reckenschufs, *A* 83, 343)— $\text{B}^+(\text{H O})_2(\text{V}_2\text{O}_5)_3$, 7aq (Bailey, *C J* 45, 692)— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$, plates (Loschmidt, *J* 1865, 375)—Benzene sulphate [89°] (Westenhoff, *Am* 10, 129)

Tetra methyl ammonium hydroxide NMe_4OH Heat of neutralisation (by HCl) 27,900 (Muller, *A Ch* [6] 15, 531) Obtained by digesting NMe_2I with moist Ag_2O (Hofmann, *Tr* 1850, 93, *C J* 4, 321) White crystalline deliquescent mass, v e sol water. Absorbs CO_2 with avidity. Its solution is strongly alkaline and caustic. Decomposed by heat into NMe_2 and MeOH (Hofmann, *B* 14, 494) Neutralises acids, forming the following salts

Iodoform NMe_4I SG 11 1827, 105 1831 (Clarke, *Am S* [3] 16, 401) The chief product of the action of MeI on ammonia and on mono, di, and tri methylamine. Best obtained by heating a solution of NH_3 in methyl alcohol with MeI at 100° – 120° (Lawson a Collie, *C J* 53, 624) Dimetric prisms (from water) Sl sol water, almost insol alcohol, insol ether. Decomposes at a dull red heat into NMe_2 and MeI . Unites with iodoform forming red crystals of $\text{NMe}_4\cdot 12\text{CHI}_3$. When heated with liquefied NH_3 , in which potassium has been dissolved, the products are KI , NMe_2 , and ethane (Thompson a Cundall, *C J* 53, 761) Unites with halogens, forming NMe_4I , (Welzien, *A* 91, 41, 99, 1), NMe_4I , [130°], NMe_4I , [110°] (Geuther, *A* 240, 68), NMe_4I , NMe_4ICl , $\text{NMe}_4\text{I}_2\text{Cl}$, (NMe_4I) $_2\text{Cl}$, (W), NMe_4IBr , [190°] (Dobbin a Masson, *C J* 49, 851), and $\text{NMe}_4\text{I}_2\text{Cl}$, [216° – 220°] The compound NMe_4I is converted by ammonia into $\text{NMe}_4\text{I}\cdot\text{NH}_3$, a dark-coloured explosive body (Stahlschmidt, *P* 119, 421)— NMe_4HgI_2 , small light-yellow prisms, m sol alcohol— $(\text{NMe}_4)_2\cdot 3\text{HgI}_2$, lemon-yellow scales (Risse, *A* 107, 223)— $(\text{NMe}_4)_2\cdot 2\text{BiI}_3$, amorphous scarlet pp (Kraut, *A* 210, 316)— $\text{NMe}_4\cdot 12\text{HgCy}$, white crystals. On heating for a

long time at 200° it is converted into the isomeric $\text{NMe}_2\text{CyHgICy}$ (Claus & Merck, *B* 16, 2738)

Bromide NMe_2Br *S* 55 26 at 15° Obtained by neutralising the hydroxide by HBr Very deliquescent needles Dissociates at 360° into NMe_2 and MeBr (Lawson & Collier, *C J* 53, 625) Forms crystalline compounds with the halogens (Dobbin & Masson, *C J* 49, 848) — (NMe_2Br) $\cdot\text{PtBr}_2$ regular octahedra (Topsoe)

Chloride NMe_2Cl *H.F.* 27,500 (Müller, *BI* [2] 44, 192) Deliquescent crystals Decomposed above 360° into NMe_2 and, doubtless, MeCl (*L a C*) — (NMe_2Cl) $\cdot\text{HgCl}_2$ trimetric crystals (*T*) — (NMe_2Cl) $\cdot\text{HgCl}_2$ rhombohedra — (NMe_2Cl) $\cdot\text{CuCl}_2$ trimetric crystals — $\text{NMe}_2\text{AuCl}_2$ dimetric crystals

Fluoride NMe_2F From the hydroxide and HF Radiating crystals Decomposes at 180° into NMe_2 and MeF (*L a C*)

Nitrate NMe_2NO_3 *S* (94 p.c. alcohol) 3 at 11° Obtained, together with NMe_2HNO_2 , $\text{NMe}_2\text{H}_2\text{NO}_2$, and NMe_2HNO , by heating methyl nitrate with NH_3 dissolved in MeOH (Duvillier & Buisson, *C R* 90, 872) The di and tri methylamine are formed in very small quantity (Duvillier & Malhot, *C R* 100, 177) Formed also by treating NMe_2I with AgNO_3 (Lawson & Collier, *C J* 53, 628) Needles or plates, v. sol water, sl. sol. cold alcohol Not attacked by boiling KOH Above 300° it yields NMe_2 , formic acid, MeNO_2 , and NO (*L a C*)

Nitrite NMe_2NO_2 From NMe_2I and AgNO_2 Deliquescent crystals Decomposed above 300° into NMe_2 , MeNO_2 , Me_2O , NO , and oxygen (*L a C*)

Sulphate (NMe_2) $\cdot\text{SO}_4$ [280°] Deliquescent crystals Decomposed above 280° into NMe_2 and $\text{NMe}_2\text{SO}_4\text{Me}$, which then undergoes further decomposition (*L a C*)

Chromates (NMe_2) $\cdot\text{CrO}_4$ yellow trimetric crystals, v. sol water (Hjortdahl, *J* 1882, 475) — (NMe_2) $\cdot\text{Cr}_2\text{O}_7$ orange trimetric tables, v. sol water

Sulphite $\text{NMe}_2\text{SO}_3\text{H}$ aq. [180°] Decomposes above 300°, yielding NMe_2 , SO_2 , MeOH , and other products (*L a C*)

Sulphydrate NMe_2SH Very deliquescent Decomposes above 200° into NMe_2 and MeSH

Phosphate From NMe_2I and Ag_3PO_4 Forms a strongly alkaline solution Decomposed at a high temperature into NMe_2 , methyl alcohol, and HPO_4 (*L a C*)

Vanadate NMe_2VO_4 (Bailey, *C J* 45, 693)

Carbonates $\text{NMe}_2\text{CO}_2\text{H}$ *H.F.* 20,570 (Müller) Obtained by saturating a solution of the base with CO_2 (*L a C*) Deliquescent crystals, decomposing above 180° into NMe_2 , methyl alcohol, and CO_2 — (NMe_2) $\cdot\text{CO}_2$ *H.F.* 19,100 Obtained by acting on NMe_2I (2 mols) with Ag_2CO_3 , $\frac{1}{2}\text{Ag}_2\text{O}$ (Müller, *BI* [2] 44, 191)

Oxalate (NMe_2) $\cdot\text{C}_2\text{O}_4$ Formed from NMe_2OH and oxalic acid, or from NMe_2I and silver oxalate Deliquescent crystals, decomposed above 360° into NMe_2 and methyl oxalate, the latter being further resolved into Me_2O , CO , and CO_2

Cyanide NMe_2Cy Prisms Sublimes at 226° V. sol water, m. sol alcohol, insol ether and chloroform (Claus & Merck, *B* 16, 2738) — $\text{NMe}_2\text{CyHgCy}$, [275° uncor.] Yellow crystals — $\text{NMe}_2\text{CyAgCy}$, [212° uncor.] From AgCy

and NMe_2I or NMe_2Cy (Thompson, *B* 16, 2338) Long colourless prisms or slender needles, v. sol water and alcohol, insol ether On dry distillation it yields NMe_2 , acetonitrile, and methyl carbamine

Ferrocyanides (NMe_2) $\cdot\text{FeCy}_2$ 13aq Laminar granular mass (Barth, *B* 8, 1484) — (NMe_2) $\cdot\text{H}_2\text{FeCy}_2$ 2aq (E. Fischer, *A* 190, 184)

Ferricyanide (NMe_2) $\cdot\text{FeCy}_3$ 3aq From NMe_2I and silver ferricyanide (Bernheimer, *B* 12, 408) Unstable hygroscopic prisms, sol water, insol alcohol

Cobaltcyanide (NMe_2) $\cdot\text{CoCy}_2$ 13aq Yellow tables (*C a M*)

Acetate NMe_2OAc [*c* 70°] From NMe_2OH and HOAc Deliquescent needles, decomposed at 200° into NMe_2 and MeOAc (*L a C*)

Benzoate NMe_2OBz [220°–230°] Long deliquescent needles Decomposed above 230° into NMe_2 and MeOBz (*L a C*)

Cyanurate $\text{NMe}_2\text{OC}_3\text{N}_3(\text{OH})_2$ aq (Claus, *J pr* [2] 38, 225)

Picrate [313°] (Lossen, *A* 181, 374)

Trimethylamine iodo-methyle iodide NMe_2CHI_2 From NMe_2 and methyleneiodide (Hofmann) Needles Not attacked by NH_3 Moist silver oxide gives $\text{NMe}_2(\text{OH})\text{CHI}_2$ and $\text{NMe}(\text{OH})\text{CH}_2\text{OH}$ It yields the platinum salt $\text{PtCl}_4(\text{NMe}_2\text{ClCHI}_2)_2$

Trimethylamine ethyle-iodide $\text{C}_2\text{H}_5\text{NI}$ *z* NMe_2EtI From NMe_2 and EtI (Müller, *A* 108, 1) Gives the following derivatives (Topsoe, *J* 1883, 620) — (NMe_2EtCl) $\cdot\text{HgCl}_2$ trimetric crystals — ($\text{NMe}_2\text{EtClHgCl}_2$) monoclinic crystals — ($\text{NMe}_2\text{EtCl}(\text{HgCl}_2)_2$) trimetric crystals — (NMe_2EtCl) $\cdot\text{CuCl}_2$ trimetric crystals — Aurochloride $\text{NMe}_2\text{EtAuCl}_2$ dimetric crystals — (NMe_2EtCl) $\cdot\text{PtCl}_2$ regular crystals — Picrate [300°] (Lossen, *A* 181, 374) The ethyle hydroxide is decomposed on distillation into NMe_2 , ethylene, and water NMe_2EtCl on distillation yields MeCl , NMe_2Et , and NMe_2

Trimethylamine ethyle tri-iodide NMe_2EtI_3 [64°] Regular crystals (Ludecke, *A* 240, 85)

Tri-methylamine ethyle penta iodide NMe_2EtI_5 [26°], dark green tables (Geuther, *A* 240, 66)

Trimethylamine ethyle enne-iodide

NMe_2EtI_9 [38°], black green crystals

Trimethylamine bromo-ethyle bromide

$\text{C}_2\text{H}_5\text{Br NMe}_2\text{Br}$ From NMe_2 and ethylene bromide at 45° (Hofmann, *C R* 47, 558) Needles, v. sol hot alcohol Ammonia as well as moist Ag_2O converts it into $\text{C}_2\text{H}_5\text{NMe}_2\text{OH}$ — ($\text{C}_2\text{H}_5\text{Br NMe}_2\text{Cl}$) $\cdot\text{PtCl}_4$ Octahedral crystals — $\text{C}_2\text{H}_5\text{Br NMe}_2\text{I}$ (Baeyer, *A* 140, 312)

Trimethylamine iodo ethyle iodide

$\text{C}_2\text{H}_5\text{I NMe}_2\text{I}$ From neurine, HI , and phosphorus (Baeyer, *A* 140, 309, 142, 324) Crystalline, sl. sol cold water Moist Ag_2O yields $\text{C}_2\text{H}_5\text{NMe}_2\text{OH}$ — ($\text{C}_2\text{H}_5\text{I NMe}_2\text{Cl}$) $\cdot\text{PtCl}_4$ octahedra

Trimethylamine allylo bromide $\text{C}_3\text{H}_5\text{NBr}$ *z* $\text{NMe}_2\text{C}_3\text{H}_5\text{Br}$ Forms a dibromide $\text{NMe}_2\text{C}_3\text{H}_5\text{Br}_2$ [175°] of which the gold salt melts at 148° (Partheuil, *B* 22, 3317)

Trimethylamine bromo-allylo-bromide

$\text{NMe}_2\text{Br C}_3\text{H}_5\text{CH OCHBr}$ [165°] Formed from $\text{NMe}_2\text{O}, \text{C}_3\text{H}_5\text{Br}$, and alcoholic KOH Colourless prisms v. sol water and alcohol, insol ether,

gives a perbromide $\text{NMe}_2\text{BrCH}_2\text{CHBrCHBr}_2$, crystallising in scales [156°]—Platinochloride ($\text{C}_2\text{H}_5\text{BrNMe}_2\text{Cl}$), PtCl_2 , [220°]—Aurochloride $\text{C}_2\text{H}_5\text{BrNMe}_2\text{AuCl}$, [181°]

Trimethylamine propylo-iodide NMe_2PrI [190°] (Langeli, *G* 16, 385)

Trimethylamine iodo-propylo-iodide $\text{NMe}_2\text{C}_2\text{H}_4\text{I}$ [151°] From the allylo iodide and HI at 100° (Partheil, *B* 22, 3320) Colourless needles, sol water and alcohol, insol ether Alcoholic KOH regenerates the allylo-compound—($\text{C}_2\text{H}_5\text{I NMe}_2\text{Cl}$), PtCl_2 , [237°]—Aurochloride ($\text{C}_2\text{H}_5\text{I NMe}_2\text{Cl}$) AuCl , [135°]

Trimethylamine trimethenyl bromide

$\text{NMe}_2\text{BrCH} \begin{array}{c} \text{CH} \\ \parallel \\ \text{CH} \end{array}$ From the bromo allylo-bromide and alcoholic KOH —Aurochloride ($\text{NMe}_2\text{Cl C}_2\text{H}_5\text{AuCl}$)

Dibromide $\text{NMe}_2\text{BrCH} \begin{array}{c} \text{CHBr} \\ \parallel \\ \text{CHBr} \end{array}$ [187°]

From the preceding and Br Colourless, somewhat hygroscopic crystals Forms a platinochloride [232°] and an aurochloride [193°] both crystallising in tables

Trimethylamine bromo-pentenyl bromide $\text{C}_2\text{H}_5\text{BrNMe}_2\text{Br}$ Formed from trimethylamine and di bromo amylene (valerylene bromide) (Ladenburg, *B* 14, 231, 1342) With HI it forms $\text{C}_2\text{H}_5\text{BrNMe}_2\text{I}$ Silver chloride forms $\text{C}_2\text{H}_5\text{BrNMe}_2\text{Cl}$, whence ($\text{C}_2\text{H}_5\text{BrNMe}_2\text{Cl}$), PtCl_2 , and $\text{C}_2\text{H}_5\text{BrNMe}_2\text{ClAuCl}$, both crystalline

Trimethylamine isoamyl triiodide $\text{NMe}_2\text{C}_2\text{H}_4\text{I}_3$ [80°] From NMe_2 and $\text{C}_2\text{H}_5\text{I}$, the product being treated with iodine Dark-brown prisms, nearly insol water, v sol alcohol

TRIMETHYLAmmELIDE v vol u p 325

DI-METHYL-AMMELINE v vol u p 321

METHYL-AMYL-ACETAL v ALDEHYDE

METHYL-ISOAMYL-ANILINE $\text{C}_2\text{H}_5\text{N}$ v $\text{C}_2\text{H}_5\text{NMe C}_2\text{H}_4\text{N}$ (257°) $\text{SG} \approx 906$ Obtained together with C_2H_5 and water by distilling $\text{C}_2\text{H}_5\text{NMeEtC}_2\text{H}_4\text{OH}$ (Hofmann, *A* 79, 15) Formed also by heating dimethylaniline with isoamyl bromide (Claus & Rautenberg, *B* 14, 622)— $\text{B}^+\text{H}_2\text{PtCl}_2$ crystalline pp—(B^+HI), 3BiI_3

METHYL AMYL ARSINE v Organic compounds of ARSENIC

METHYL AMYL BENZENE v AMYL TOLUENE

Di methyl isoamyl benzene v AMYL XYLENE
METHYL-ISOAMYL-BENZENE SULPHONIC ACID $\text{CH}_2\text{C}_2\text{H}_4(\text{C}_2\text{H}_5)_2\text{SO}_3\text{H}$ From p isoamyl toluene by sulphonation (Fitting & Bigot, *A* 141, 166) — KA^+ The Ba salt is a deliquescent gummy mass

Di methyl isoamyl benzene sulphonic acid $(\text{OH})_2\text{C}_2\text{H}_4(\text{C}_2\text{H}_5)_2\text{SO}_3\text{H}$ Formed by sulphonating isoamyl-xylene (F & B) The K and Ba salts were not obtained in crystals

METHYL AMYL CARBINOL v HEPTYL ALCOHOL

DI METHYL AMYLENE DIKETONE $\text{C}_2\text{H}_5\text{O}_2$ v $\text{CEt}_2(\text{COCH}_2)_2$ Di ethyl-acetyl acetone (c 203°) From $(\text{CH}_3\text{CO})_2\text{CEtNa}$ and EtI at 180° (Combes, *A Ch.* [6] 12, 250) Liquid Split up by KOH into $\text{CH}_3\text{CO}_2\text{K}$ and $\text{CH}_3\text{COCH}_2\text{Et}$

Di methyl amylenone diketone $\text{C}_2\text{H}_5\text{O}_2$ v $(\text{CH}_3\text{COCH}_2\text{CH}_2)_2\text{CH}_2$ Di acetyl-pentane

[49°] (212°–215° at 300 mm) From the carboxylic ether and a dilute solution of KOH in MeOH (Kipping & Perkin, *C J* 55, 337) v sol cold ether, alcohol, acetone, chloroform, and light petroleum Cold conc HNO_3 dissolves it without decomposition Conc H_2SO_4 forms a colourless oil $\text{C}_2\text{H}_5\text{O}$

Di oxim $(\text{CH}_3\text{C}(\text{NOH})\text{CH}_2\text{CH}_2)_2$ [85°] Colourless moss like crystals, v sol cold water

DI METHYL AMYLENE DIKETONE CARBOXYLIC ACID

$\text{CO}_2\text{HCHAcCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{COCH}_2$ From its ether and KOH dissolved in MeOH Liquid, miscible with water Decomposed by heat into CO_2 and the diketone

Ethyl ether EtA^+ (240° at 200 mm) Prepared from sodium aceto acetic ether and $\text{CH}_3\text{COCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{Br}$ (Kipping & Perkin, *C J* 55, 333) Thick oil Alcoholic NH_3 converts it into $\text{AcCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{C} \begin{array}{c} \text{CMe} \\ \parallel \\ \text{CO} \end{array} \text{NH}$

[c 235°], which forms monoclinic crystals, $a b c = 7487.1 \ 3997.7 \ 79^\circ 11'$ This 'dehydro amide' yields an acetyl derivative $\text{C}_{12}\text{H}_{17}\text{AcNO}_2$, an oil, converted by boiling water into the amide $\text{CH}_3\text{COCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CONH}_2$, which melts between 200° and 228°

METHYL AMYL ETHER v METHYL AMYL OXIDE

METHYL AMYL KETONE $\text{C}_2\text{H}_5\text{O}$ v $\text{CH}_3\text{COCHCH}_2\text{CH}_2\text{CHCH}_2\text{CH}_2$ (151°) $\text{SG} \approx 837$ Formed by oxidising sec heptyl alcohol obtained from *n* heptane (Schorlemmer, *A* 161, 279, 217, 149) Fragrant liquid Unites with NaHSO_4 Yields on oxidation acetic and *n* valeric acids Formed also by dissolving heptinene C_2H_5 in conc H_2SO_4 , and distilling the product with water (Behal, *A Ch.* [6] 15, 270)

Methyl isoamyl ketone $\text{C}_2\text{H}_5\text{O}$ v $\text{CH}_3\text{COCH}_2\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_3)_2$ (144°) $\text{SG} \approx 828$, μ 818 (Rohn, *A* 190, 308), η 821 (Wagner, *J R* 16, 705)

Formation—1 By heating a mixture of calcium hexoate with calcium acetate (Schmidt, *B* 5, 604)—2 By the action of zinc isoamyl on acetyl chloride (Popoff, *A* 145, 283)—3 By oxidising the corresponding heptyl alcohol (Grimshaw *A* 166, 169)—4 By boiling isobutyl aceto acetic acid with aqueous KOH the yield being 70 p c (Purdie, *C J* 39, 467)

Properties—Oil Reduced by sodium to sec heptyl alcohol and di isopropyl pinacone CrO_2 oxidises it to acetic, isovaleric, and isohexonic acids It combines with NaHSO_4

Methyl amyl ketone Me CO CHMePr (142°–147°) From methyl propyl aceto acetic ether (E J Jones, *A* 226, 293) Oil, smelling of peppermint

Methyl amyl ketone $\text{CH}_3\text{COCHMePr}$ (135°) $\text{SG} \approx 815$ One of the products of the saponification of methyl isopropyl aceto acetic ether (Van Romburgh, *R T C* 5, 235) Does not combine with NaHSO_4 Does not give a solid phenyl hydrazide

Methyl amyl ketone $\text{CH}_3\text{COCH}_2\text{CMe}_2$ (125°–130°) Obtained by oxidising the alcohol $\text{CMe}_2\text{CH}_2\text{CMe}_2\text{OH}$ (Butlerow, *A* 189, 78) Oxidised by CrO_2 to acetic acid and $\text{CMe}_2\text{CO}_2\text{H}$ Does not combine with NaHSO_4

Methyl amyl ketone CH_3COCHEt (138°), $\text{SG} \approx 817$ Obtained by boiling di ethyl aceto-

acetic ether with baryta water (Frankland & Duppe, *A* 138, 212) Forms an oily compound with NaHSO_3 .

Methyl amyl ketone $\text{CH}_3\text{CO CMe}_2\text{Et}$ *Methyl-amyl-pinacolin* (132°) SG 2 842, 21 825 Obtained by the action of ZnMe_2 on $\text{CMe}_2\text{Et COCl}$ (Wyschnegradsky, *A* 178, 108) CrO_3 oxidises it to HOAc and $\text{CMe}_2\text{Et CO}_2\text{H}$

Methyl amyl ketone $\text{CH}_3\text{CO C}_4\text{H}_9$ (142°–146°) From *sec*-heptyl alcohol derived from petroleum heptane (90°) Gives acetic acid on oxidation (Schorlemmer, *A* 166, 172)

Methyl isoamyl diketone $\text{CH}_3\text{CO CO C}_4\text{H}_9$ *Methyl isoamyl-glyoxal* (163°) SG 2 8814 From methyl nitrosohexyl ketone (Otto & Pechmann, *B* 22, 2123) Oil, solidified by cold

Phenyl-hydrazide [100°] White needles (from benzene ligroin)

Di-phenyl-di hydrazide. [114°] Needles (from dilute alcohol)

Oxam [173°] Needles

Oxam-phenyl-hydrazide [132°] White needles (from benzene ligroin)

METHYL AMYL KETONE CARBOXYLIC ACID $\text{CH}_3\text{CO CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ [30°] A product of the action of a boiling solution of KOH in MeOH upon dimethyl-amylene diketone carboxylic ether (Kipping & Perkin, *jun*, *C J* 55, 338) Also from sodium malonic ether and $\text{CH}_3\text{CO CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{Br}$, the resulting dicarboxylic acid being distilled Crystalline plates, v sol water— Ag^+ colourless plates

METHYL ISO AMYL OXIDE $\text{C}_7\text{H}_{14}\text{O}$ *ze* $\text{CH}_3\text{O C}_4\text{H}_9$ Mol w 102 (92°) VD 3 74 SV 148 1 (Schiiff) From MeONa and isoamyl iodide (Williamson, *C J* 4, 233)

METHYL-AMYL-PIPERIDINE $\text{C}_{11}\text{H}_{21}\text{N}$ *ze* $\text{C}_4\text{H}_9\text{N}(\text{C}_2\text{H}_5)(\text{CH}_3)$ (190°–193°) Prepared by dry distillation of the alkaline hydrate obtained by the action of moist Ag_2O on amyl piperidine methylo iodide (Schotten, *B* 15, 422) Colourless fluid Sl sol water With MeI it forms a crystalline methylo iodide— B^+HCl hygroscopic salt— $(\text{B}^+\text{HCl})_2\text{PtCl}_6$ sparingly soluble pp, melts at [140°]

METHYL AMYL SULPHIDE $\text{CH}_3\text{S C}_4\text{H}_9$ (137°) VD 58 6 From NaSC_2H_5 and MeI (Obermeyer, *B* 20, 2924)

METHYL AMYL DI-THIO-CARBONATE $\text{*CO}(\text{SMe})(\text{SC}_2\text{H}_5)$ (c 140°) From $\text{Cl CO SC}_2\text{H}_5$ and NaSMe (Schöne, *J pr* [2] 82, 244) Liquid, smelling like CS_2 With ammonia it gives HSC_2H_5 , urea, and HSMe Alcoholic potash forms K_2CO_3 , methyl mercaptan, and HSC_2H_5

METHYL-ANHYDRO-ACETONE-BENZYL *v*. vol 1 p 463

METHYL-ANILINE $\text{C}_6\text{H}_5\text{NHMe}$ Mol w 107 (193° uncor) (Friswell & Green, *B* 19, 2035) SG 15 976 HF –5500 H C v 973,000 (Petit, *C R* 107, 266) *Heat of neutralisation* (by HCl) 6,910 (Vignon, *C R* 106, 1722)

Formation—1 Together with dimethylaniline from aniline and MeI or MeBr (Hofmann, *A* 74, 150, *B* 10, 591, cf Kern, *B* 10, 135)—2 Together with dimethylaniline by heating methyl alcohol with aniline and HCl at 200° under pressure (Girard, *BI* [2] 24, 120, cf Poirner & Chappat, *J* 1866, 903)—3 By heating aniline hydrobromide (or hydriodide) with 10 p.c. more than the calculated quantity of methyl

alcohol to 150° for 8 hours, the yield is 34 p.c. of the theoretical (Reinhardt & Staedel, *B* 16, 29, cf Kramer & Grodzky, *B* 18, 1006)—4 By heating acetanilide with alcoholic sodium ethylate at 170°–200° under pressure (Seifert, *B* 18, 1355)—5 By adding sodium to a solution of acetanilide in xylene, treating the resulting sodium-acetanilide with MeI and boiling the product ($\text{C}_6\text{H}_5\text{NMeAc}$) with alcoholic potash (Hepp, *B* 10, 327)—6 From its formyl derivative (Pictet & Crépieux, *B* 21, 1108)—7 By boiling diazobenzene methyl anilide (100 g) with conc HCl (200 cc), making alkaline with NaOH , and distilling with steam, yield 40 g (Friswell & Green, *B* 19, 2035)

Purification—By the action of MeOH and HCl on aniline a mixture of bases is obtained On adding dilute H_2SO_4 aniline sulphate separates, and the bases liberated from the filtrate may then be heated with AcCl On pouring the product into water the acetyl derivative of methyl aniline separates in long needles, while dimethyl aniline hydrochloride remains in solution The acetyl derivative may be quickly saponified by boiling with conc HClAq (Hofmann, *B* 7, 523) The mixture of bases may also be treated with nitrous acid, whereby a diazo benzene salt, phenyl-methyl-nitrosamine, and nitroso dimethylaniline are formed The nitrosamine, being insoluble in water and acids, separates as a yellow oil, and may be recovered by tin and HCl into methyl aniline (Noelting & Boasson, *BI* [2] 28, 2)

Properties—Oil Its aqueous solution is not coloured by bleaching powder With NaOBr it gives a yellow pp (Deniges, *C R* 107, 662) With CuSO_4 it forms a compound $\text{B}(\text{CuSO}_4)_4\text{CuO}$ (Lachovitch, *M* 9, 514)

Estimation—1 It is treated with a mixture of Ac_2O (1 vol) and di methyl aniline (10 vols), water is added after the reaction, and the solution titrated with phenol phthalein The di methyl aniline does not interfere with the reaction, and the mixture of it with the acetic anhydride keeps well (Girard, *BI* [3] 2, 142)—2 In a mixture of aniline, methylaniline, and dimethyl aniline the aniline is first determined by diazotisation and ppn by (8) naphthol disulphonic acid (*R*) and NaCl Another portion of the mixed bases (2 g) is mixed with Ac_2O (4 g), and, after 30 minutes water (50 cc) is added The liquid is boiled to decompose the excess of Ac_2O , and the acid solution titrated with Na_2CO_3 using phenol phthalein as indicator The amount of Ac_2O found plus that required by the aniline previously determined is then subtracted from the amount taken, and gives a measure of the methyl-aniline present (Reverdin & De la Harpe, *B* 22, 1004)—3 In a mixture of mono- and di methyl aniline the amount of the former present may be known by observing the rise of temperature on mixing with an equal volume of Ac_2O

Reactions—1 HNO_3 gives off red fumes on tanning CO_2 , and forms tetra-nitro-methyl aniline (Van Romburgh, *R T C* 2, 81)—2 NaNO_2 added to a solution of its hydrochloride forms phenyl-methyl-nitrosamine $\text{C}_6\text{H}_5\text{NMeNO}$, a yellow oil solidifying when cooled as needles [12°–15°] It gives no reaction with gallic acid (Reverdin & De la Harpe, *B* 22, 1006)—3 Boiling sulphur forms methenyl amido-phenyl mercap-

tan and crystalline C_6H_5NS , [89°] (360°) (Möhlau a Krohn, *B* 21, 59) —4 A solution of methyl-aniline sulphate saturated with SO_2 forms with an aqueous solution of alloxan small yellowish prisms of $CO \begin{smallmatrix} \text{NH} & \text{CO} \\ \diagdown & / \\ \text{NH} & \text{CO} \end{smallmatrix} C(OH) SO_2 NH_2 PhMe 2aq$ (Pelizzari, *A* 248, 148) —5 An aqueous solution of alloxan forms $(C_6H_5N_2O_2)(NHPhMe)$, a compound crystallising in white scales, with a hydrochloride crystallising in prisms —6 *Diazobenzene chloride* and aqueous $NaOAc$ form $PhNMe N NPh$, a yellowish oil, decomposed by dilute H_2SO_4 into diazobenzene sulphate (or phenol) and methyl-aniline, and by $SnCl_2$ and HCl into phenyl hydrazine and methyl aniline (Nöbling a Binder, *B* 20, 3017) —7 *p-Nitro-diazobenzene chloride* and $NaOAc$ form $C_6H_5(NO_2) N N C_6H_5NHMe$ crystallising in red needles [134°], v sol hot alcohol (N a B) —8 *Bromo-acetophenone* forms $C_6H_5 CO CH_2 NPhMe$ in the cold, and on boiling it gives phenyl indole and phenyl methyl-indole (Cullmann, *B* 21, 2595)

Salts — $B^+H^+PtCl_6^-$ Yellow scales Decomposed by boiling water (De Coninck, *Bl* [2] 45, 131) — $B^+H^+CdBr_4^-$ Trimetric crystals (Hjortdahl, *J* 1882, 522) — $B^+H^+SnBr_6^-$ Monoclinic crystals — $B^+HSO_4^-$ Needles (Classens a Lundvall, *B* 13, 1703)

Formyl derivative $C_6H_5NMeCHO$ [12 5°] (N a L) (250°) (N a L), (256°) (Pictet a Crépieux, *B* 21, 1108) $SG \frac{1}{2}$ 1097 From sodium formamide and MeI (Norton a Livermore, *B* 20, 2273) Formed also from methyl-aniline and the hydrochloride of formimide ether (Pinner, *B* 16, 1652) Oil, could not be solidified by Pictet When boiled with 124 p c nitric acid it yields dimethyl-aniline

Acetyl derivative C_6H_5NMeAc 'Ex-algin' [101 5°] (Kamensky, *A* 214, 236) (256°) (P a C) Formed from sodium acetanilide and MeI (Hepp, *B* 10, 328, Hofmann, *B* 10, 599) Formed also by the action of acetyl bromide on dimethyl-aniline (Staedel, *B* 19, 1947) White needles and tablets, sl sol cold water, v sol dilute alcohol As a medicine it has an energetic action on the cerebro spinal system (Dujardin Beaumetz, *C R* 108, 571, cf Giraud, *C R* 108, 749) It is a good antiseptic Boiling nitric acid forms (4, 2, 1)-di nitro methyl aniline

Thio acetyl derivative $CH_3CS NPhMe$ [59°] (290°) From the acetyl derivative and sulphide of phosphorus (Wallach, *B* 13, 528) Monoclinic plates (from $CHCl_3$) Insol. water and alkalis, sol alcohol and ether

Propionyl derivative $CH_3CH_2CO NPhMe$ [58 5°] From sodium propionamide and MeI (Norton a Allen, *B* 18, 1998) With boiling HNO_3 (100 pts of SG 1029) it yields (4, 2, 1) di-nitro methyl aniline

Oxalyl derivative $(CONPhMe)_2$ (250°) Forms oxalic acid, alcohol, and methyl-aniline (Norton a Livermore, *B* 20, 2273) Boiling nitric acid converts it into di nitro-methyl-aniline [177°]

Benzoyl derivative C_6H_5NMeBz [68°] From methyl-aniline and $BaCl_2$ (Hepp, *B* 10, 329) Formed also by heating di methyl aniline with benzoyl chloride at 180° (Hess, *B* 18, 685) Large monoclinic crystals, insol water, but v

sol other solvents Gives a mono nitro- derivative [136°]

Nitrosamine $PhMeNNO$ [12°-15°] From methyl-aniline hydrochloride and aqueous $NaNO$, (Hepp, *B* 10, 329, Fischer, *A* 190, 151, Reverdin a De la Harpe, *B* 22, 1006) Yellow oil, solidified by cold Reduced by tin and HCl to methyl-aniline Gaseous HCl passed into its solution in alcohol ether forms the isomeric [4 1] $NO C_6H_5NHMe$ [118°] which crystallises from water in prisms, v sol alcohol, and is converted by heating with aqueous $NaOH$ into *p* nitrosophenol and methylamine (Fischer a Hepp, *B* 19, 2991)

Di-methyl-aniline $C_6H_5NMe_2$ Mol w 121 [2°-2 5°] (Friswell a Green, *private communication*) (193°) $SG \frac{2}{3}$ 9575 $\mu_n = 1.559$ (Bruhl, *A* 235, 14) SH (9°-82°) 443 (Schiff, *G* 17, 286) Heat of neutralisation (by HCl) 6,810 (Vignon, *C R* 106, 1722) Formed by heating aniline with MeI or $MeCl$

Preparation —1 Aniline hydrobromide (or hydroiodide) is heated with (2 mols + 10 p c excess of) methyl alcohol to 150° for 8 hours, the yield is 95 p c of the theoretical (Reinhardt a Staedel, *B* 16, 29, cf Lauth, *Bl* 7, 448) —2 Aniline (18 pts) saturated with HCl is mixed with a further quantity (75 pts) of aniline and methyl alcohol (75 pts) The mixture is heated at 230° in closed vessels until the internal pressure falls The use of a comparatively small quantity of HCl avoids the formation of toluidine and allows of the use of iron vessels The HCl is sometimes replaced by H_2SO_4 (Schoop, *Chem Zeit* 11, 253)

Purification —Dimethyl-aniline can be separated from methyl aniline by the methods described under methyl aniline It can also be purified by freezing (Hubner, *A* 224, 347)

Reactions —1 When its vapour is passed through a red hot tube it forms benzonitrile (25 p c), carbazole, NH_3 , benzene, and HCy (Nietzki, *B* 10, 474) —2 When heated in a current of HCl at 180° the products are $MeCl$ and aniline (Lauth, *B* 6, 677) —3 With sodium hypobromite it gives a greenish yellow pp in the cold and a red pp on heating (Denigès, *C R* 107, 662) —4 Bromine (1 mol) at 115° forms methyl violet and naphthalene (Brunner a Brandenburg, *B* 11, 697) —5 By nitration with a mixture of equal volumes of ordinary conc HNO_3 and water at 0° di nitro di-methyl aniline $C_6H_5(NO_2)_2NMe$ [4 2 1] is formed (yield 116 p c) If the mixture is allowed to get warm another di nitro di methyl aniline [probably 5 3 1] is formed (yield 15 p c) By further nitration of the first isomeride by boiling it with fuming nitric acid tri nitro phenyl methyl nitramide $C_6H_5(NO_2)_3NMe(NO_2)$ [6 4 2 1] is produced By the same treatment the second isomeride is converted into di nitro phenyl methyl nitramide $C_6H_5(NO_2)_2NMe(NO_2)$ [5 3 1 7] (Mertens, *B* 19, 2123, cf Bomburgh, *R T O* 2, 31) When nitrated in presence of a large excess of H_2SO_4 (20 pts) it yields as chief product the *m* nitro-derivative whilst the *p* nitro derivative is formed in smaller quantity (Groll, *B* 19, 198, Nöbling, *B* 19, 545) —6 Combines with aluminum chloride with great evolution of heat forming long prisms [88°] (H Giraud, *Bl* [3] 1, 691).

Heated in sealed tube with 5 pts of aluminium chloride for 10 hours at 250° no change is effected. Heated in air with excess of aluminium chloride it yields a tetra methyl benzidine $(\text{CH}_3)_4\text{N}_2\text{C}_6\text{H}_4\text{N}(\text{CH}_3)_2$, small needles [195°]. This base is split at 180° by action of HCl gas into methyl chloride and benzidine [118°]—7 *Nitric oxide* passed for 12 days into a solution of dimethylaniline (500 g) in absolute alcohol (510 g) forms $\text{NMe}_2\text{C}_6\text{H}_4\text{N}(\text{CH}_3)_2$. After 3 or 4 weeks' passage of the gas there are formed a base $\text{C}_6\text{H}_4\text{N}_2$ [173°] and a violet colouring matter $\text{C}_6\text{H}_4\text{N}_2\text{O}$ (?) (Lippmann & Lange, B 13, 2136). 8 *Nitrous acid* forms nitroso di methyl aniline (q v)—9 By heating with sulphur there is formed a compound $\text{C}_6\text{H}_4\text{NS}$ which is converted

by HNO_3 into a base $\text{C}_6\text{H}_4\text{N}(\text{CH}_3)_2\text{S}$ of which

the nitrate $\text{B}'\text{HNO}_3$ crystallises in colourless needles and the platinumchloride $\text{B}'_2\text{H}_2\text{PtCl}_6$ in plates (Mohlau & Krohn, B 21, 65). The compound $\text{C}_6\text{H}_4\text{NS}$ is neither acid nor basic and

appears to be $\text{C}_6\text{H}_4\text{N}(\text{CH}_3)_2\text{S}$. It melts at

89° and forms prisms, insol water, and volatile with steam. On heating with sulphur it is converted into methenyl amido phenyl mercaptan. 10 *Chloride of sulphur* forms tetra methyl di amido di phenyl disulphide $\text{S}_2(\text{C}_6\text{H}_4\text{NMe}_2)_2$ (Hannmann, B 10, 403)—11 Heated with *persulphocyanic acid* it gives $\text{S}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ with simultaneous formation of thiocyanic acid, CS_2 , H_2S , and NH_3 (Tursini, B 17, 586)—12 Mixed with CS_2 and then treated with zinc dust and HCl it gives tetra-methyl di amido di phenyl methane [90°] and thioformic paraldehyde [212°] (Wiernik, B 21, 3204)—13 *Oxidising agents* give rise to penta methyl tri amido tri-phenyl carbinol (methyl violet) (O & E Fischer, B 11, 2099)—14 COCl_2 forms $\text{CO}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ and, at 120°, $\text{NMe}_2\text{C}_6\text{H}_4(\text{CO C}_6\text{H}_4\text{NMe}_2)_2$ —15 CCl_4 gives at 180°C $(\text{C}_6\text{H}_4\text{NMe}_2)_4$ (Hannmann, B 10, 1689). 16 *Chloroform* at 230° yields $\text{CH}(\text{C}_6\text{H}_4\text{NMe}_2)_3$ (Hannmann, B 10, 1235)—17 *Chloral hydrate* in presence of ZnCl_2 forms $\text{CCl}_3\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{NMe}_2$ (Knöfler & Boessneck, B 20, 3195)—18 *Furfuraldehyde* in presence of zinc chloride yields $\text{C}_6\text{H}_4\text{OCH}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ which crystallises in pale yellow needles [83°] and is a strong base (O Fischer, A 206, 141)—19 With *heptol aldehyde* and ZnCl_2 it also forms a condensation-product (Auger, Bl [2] 47, 42)—20 *Benzoin aldehyde* and ZnCl_2 forms $\text{C}_6\text{H}_4\text{CH}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ (O Fischer, B 10, 1624)—21 When treated in the cold with *acetyl bromide* it becomes hot and yields acetyl mono methyl aniline (Staedel, B 19, 1947)—22 *Heptyl chloride* in presence of ZnCl_2 forms a base [72.5°] (278° at 15 mm) (Krafft, B 19, 2987)—23 By heating with *benzoyl chloride* at 190°, benzoyl methyl aniline is formed with splitting off of MeCl (Hess, B 18, 685, cf Michler, B 9, 1899)—24 *Benzoin acid* (1 mol) and P_2O_5 at 200° forms di-methyl amido-benzophenone [83°] (O Fischer, A 206, 88)—25 *Phthalic anhydride* in presence of ZnCl_2 forms di-methyl-aniline phthalein—26 *Benzotrichloride* forms 'malachite green'

$(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{CCl}_3\text{C}_6\text{H}_5$. The same body is formed by the action of Bz_2O or BzCl in presence of P_2O_5 —27 *Orthoformic ether* and ZnCl_2 form $\text{CH}(\text{O}_2\text{H}_2\text{NMe}_2)_2$ —28 *Vanillin* and ZnCl_2 form $\text{C}_6\text{H}_4\text{N}_2\text{O}$ [136°] (Fischer & Schmidt, B 17, 1895)—29 A blue compound is obtained by the oxidation of dimethylaniline with *chloranil* or other chlorinated quinone. It appears to have the same constitution whichever chloro quinone is used, as on reduction it always gives a leuco base of the formula $\text{C}_{12}\text{H}_{10}\text{N}_2$, and melting point [173°]. The latter forms glistening plates, sl sol cold alcohol, v sol hot alcohol, benzene, and ether. It forms the salts $\text{B}'\text{H}_2\text{Cl}_2$, colourless crystals— $\text{B}'\text{H}_2\text{Cl}_2\text{PtCl}_6$, fine needles— $\text{B}'\text{Me}_2\text{Cl}_2$, crystals, sol water, sl sol alcohol, with wet Ag_2O it gives an alkaline fluid (Meister, Lucius, & Bruning, B 13, 212, 2100, Wöhlerhaus, B 14, 1952)—30 *Acetone* saturated with SO_2 forms $(\text{C}_6\text{H}_5\text{O})(\text{SO}_2)(\text{NMe}_2\text{Ph})$ crystals in lustrous plates, v sol water and alcohol, insol acetone (Boessneck, B 21, 1906). Acetone and ZnCl_2 at 150° forms $\text{CMe}_2(\text{C}_6\text{H}_4\text{NMe}_2)_2$ [83°] (Doebner, B 12, 810)—31 Di-methylaniline dissolved in a saturated solution of SO_2 and mixed with an aqueous solution of *alloxan* forms $(\text{C}_6\text{H}_4\text{N}_2\text{O})(\text{NMe}_2\text{Ph})\text{H}_2\text{SO}_4$ 4aq crystallising in monoclinic plates, $a, b, c = 1.3399, 1.3394, \beta = 93^\circ 23'$ (Pellizzari, A 218, 148, G 18, 329)—32 A saturated aqueous solution of *alloxan* forms a compound $\text{C}_{12}\text{H}_{10}\text{N}_2\text{O}_4$ aq crystallising in colourless needles, sl sol water, decomposing at 250° (Pellizzari, G 17, 409). The compound forms a crystalline hydrochloride, nitrate, and oxalate, and yields a silver salt $\text{C}_{12}\text{H}_{12}\text{AgN}_2\text{O}_4$. It is decomposed by alkalis forming a compound $\text{C}_{11}\text{H}_{12}\text{N}_2\text{O}_5$, decomposing at 281°—33 *s-Trinitrobenzene* forms a compound $\text{NMe}_2\text{PhC}_6\text{H}_4(\text{NO}_2)_3$ [108°] which crystallises in long dark violet needles, sl sol alcohol (Hepp, A 215, 368)—34 *Tri nitro toluene* forms a corresponding body (H)—35 *Tri nitro aniline* forms $\text{NMe}_2\text{PhC}_6\text{H}_4(\text{NO}_2)_3(\text{NH}_2)$ [141°] (Hepp).

Salts—Dimethylaniline is apparently less basic than aniline, for if a mixture of the bases is treated with an insufficient quantity of cold aqueous HCl the base left uncombined is chiefly dimethylaniline (Morley, C J 51, 580)— $\text{B}'\text{H}_2\text{SO}_4$ [80°] Sol water, insol ether and benzene. HF 8400. The normal sulphate could not be formed. At 190° the acid sulphate splits up into CO_2 and the sulphonic acid (Vignon, C R 107, 263)— $\text{B}'_2\text{H}_2\text{HgCl}_2$ [149°] Large tables or prisms, m sol hot water and hot alcohol. Prepared by adding aqueous HgCl_2 to an alcoholic solution of dimethylaniline (Klein, B 11, 1741)— $\text{B}'_2\text{Hg}_2\text{OCl}_2$ Formed together with the preceding. Small needles or glistening leaflets, m sol hot water and hot alcohol, insol cold water, v sol benzene. On heating to 100° a blue colouring matter is formed— $\text{B}'_2\text{HgCl}_2$ (Leeds, J 1882, 504)— $\text{B}'_2\text{H}_2\text{SnCl}_4$ Large monoclinic crystals (Hjortdahl, J 1882, 523)— $\text{B}'_2\text{H}_2\text{PtCl}_6$ Tables— $\text{B}'_2\text{H}_2\text{PtCl}_6$ 2aq (Reinhardt & Staedel, B 16, 29)— $\text{B}'_2\text{H}_2\text{PtBr}_6$ Brownish-red monoclinic needles— $\text{Bi}_2\text{B}'\text{HI}$ (Kraut, A 210, 324)— $(\text{Bi}_2)_2\text{B}'\text{HI}$ — $(\text{Bi}_2)_2\text{B}'\text{HI}$ — $(\text{Bi}_2)_2\text{B}'\text{HI}$ — $\text{Bi}_2\text{B}'\text{HI}$ — $\text{B}'_2\text{H}_2\text{FeCl}_2$ Lamine, sl. sol cold water, being less soluble than the methylaniline

and aniline ferrocyanides (Fischer, *A* 190, 184) — $B^{\cdot}H_2FeCy_2$ 2aq (Eisenberg, *A* 205, 266)

Methylo-iodide $C_6H_5NMe_2I$ *Phenyl trimethyl-ammonium iodide* S (alcohol) 2 2 at 8° The combination of $PhNMe_2$ and MeI takes place rapidly (Lauth, *Bl* 7, 448) It may also be obtained by shaking a mixture of aniline (1 mol) with MeI (3 mols) and KOH (2 mols) dissolved in water (Pawlinoff, *J R* 13, 448, *Bl* [2] 37, 493) Plates (from alcohol) Converted by moist Ag_2O into $C_6H_5NMe_2OH$ a deliquescent, crystalline, caustic base When the methylo iodide is distilled it splits up into NMe_2Ph and MeI , but these recombine in the receiver If, however, a current of HCl be passed through the retort NMe_2PhHCl condenses in the receiver, while MeI escapes and may be condensed in a second colder receiver (Merill, *J pr* [2] 17, 286) When treated in a sealed tube with a solution of potassium in anhydrous liquefied ammonia it yields KI , NMe_2 , and possibly benzene (Thompson a Cundall, *C J* 53, 761) Boiling conc KOH slowly decomposes $PhNMe_2I$ into di methylaniline, KI , and $MeOH$ (Claus a Rautenberg, *B* 14, 621) The methylo iodide gives rise to the following derivatives — $PhNMe_2I_2$ [115°] Brown trimetric plates (Geuther, *A* 240, 69) — $PhNMe_2I_3$ [87°] (Dafert, *M* 4, 500) Lustrous green monoclinic needles, $a b c = 1.794 : 1.1251$, $\beta = 69^\circ 43'$ — $PhNMe_2I_4$ [65°] Violet black plates — $PhNMe_2IZnI_2$ Trimetric crystals (Hjortdahl) — $PhNMe_2ClHgCl_2$ [188°] S 36 at 62° Needles (Hubner, *A* 224, 352) — $(PhNMe_2Cl)_2PtCl_2$ Orange needles (from water) S 33 at 74° — $(PhNMe_2)_2Cr_2O_7$ Prisms S 5 — $(PhNMe_2)_2Cr_2O_{10}$ Monoclinic crystals (Hjortdahl)

Ethyl iodide $B^{\cdot}EtI$ [125°] Identical with methyl ethyl aniline methylo iodide, KOH splits off dimethylaniline (Claus a Howitz, *B* 17, 1325) — $PhNMe_2EtI_2$ [81°] Dark violet hexagonal rhombohedra (Geuther) — $PhNMe_2EtI_3$ [50°] Lustrous bluish-green plates — $PhNMe_2EtI_4$ [45°] Violet black plates

 $C_6H_5 \begin{array}{c} \diagup CH \\ | \\ \diagdown CH \end{array} C_6H_5Me \left[\begin{array}{c} 6 \\ 5 \end{array} \right]$ Mol w 192 [203°]

(Börnstein), [200°] (Burukoff) Formed by distilling *erythro-oxo* methyl anthraquinone with zinc dust (Burukoff, *B* 20, 2070) Formed also by boiling *iso* methylanthraquinone with zinc dust and ammonia, and splitting off water from the resulting methyl hydroxanthranol by boiling with xylene (Börnstein, *B* 15, 1821) White plates — $B^{\cdot}C_6H_5(NO_2)_2OH$ red needles Gives on oxidation methyl-anthraquinone [167°] and

the corresponding anthraquinone carboxylic acid. Forms a di bromo methyl anthracene [148°]

Hexahydride $C_{14}H_{14}$ [α 66°] Formed by reducing the dilactone of benzophenone dicarboxylic acid with phosphorus and hydric iodide (Graebe a Juillard, *A* 242, 256) Plates V sol alcohol, ether, and chloroform Passed through a red hot tube it yields a hydrocarbon [195°] On oxidation it yields methylanthraquinone [154°]

(*B* 2) **Methyl-anthracene**

$C_6H_5 \begin{array}{c} \diagup CH \\ | \\ \diagdown CH \end{array} C_6H_5Me \left[\begin{array}{c} 6 \\ 5 \end{array} \right] 2$ [200°] Occurs in

coal tar oil, and hence is present in crude anthracene and phenanthrene (Japp a Schultz, *B* 10, 1049)

Formation — 1 By passing di-tolyl methane through a red hot tube (Weiler, *B* 7, 1181) — 2 By passing di tolyl ethane through a red hot tube (O Fischer, *B* 7, 1191, 8, 675) — 3 Apparently occurs among the products obtained by passing vapour of oil of turpentine through a red-hot tube (Schultz, *B* 10, 84) — 4 By the action of zinc dust at high temperatures on chrysophanic acid $C_{14}H_8O_2(OH)_2$, on emodin $C_{14}H_8O_4(OH)_2$ (Liebermann, *B* 8, 970, *A* 183, 163), on aloin (in small quantity) (E Schmidt, *B* 8, 1275, *Ar Ph* [3] 8, 496), on the acid [4 1] $CH_3C_6H_4CO_2C_6H_4CO_2H$ (Gresly, *A* 234, 238), on abietic acid (colophony), on gum benzoin (Ciamician, *B* 11, 273), on chrysarobin (Liebermann a Seidler, *A* 212, 34), and on methyl quinizarin (Nietzki, *B* 10, 2013) — 5 By boiling phenyl xylol ketone $C_6H_5CO_2C_6H_4Me$ [1 2 4] for a long time (Elbs, *J pr* [2] 35, 472) The isomeric $C_6H_5CO_2C_6H_4Me$ [1 2 5] condenses on boiling to the extent of 10 to 20 p.c. to (*B* 2) methyl anthracene, dehydrating agents either stop the reaction or split off benzoic acid

Properties — Yellowish plates (from alcohol) Sublimes in large white plates, exhibiting blue fluorescence Sl sol alcohol, ether, and $HOAc$, v sol $CHCl_3$, benzene, and CS_2 Chromic acid in $HOAc$ oxidises it to anthraquinone carboxylic acid [282°] Conc HNO_3 added to its alcoholic solution forms methyl anthraquinone Bromine in CS_2 forms a di bromo derivative [156°] (Fischer), which yields, on further bromination, a tetra bromo derivative crystallising from toluene in needles The picric acid compound melts at [93°] (Gresly)

Di-methyl-anthracene $C_{14}H_{14}$, t.e.

$C_6H_5 \begin{array}{c} \diagup CH \\ | \\ \diagdown CH \end{array} C_6H_5Me_2$ [71°] (above 360°) VD

7 19 One of the products obtained by passing benzyl mesitylene through a red hot tube Separated from the di methyl anthracene [218°] which accompanies it in smaller quantity, by crystallisation from toluene, in which the compound, melting at 71°, is extremely soluble Further purified by means of its picric acid compound (Louise, *Bl* [2] 44, 180, *A Ch* [6] 6, 191) White needles, v e sol cold benzene and toluene, m sol $HOAc$ and alcohol On oxidation with CrO_3 in $HOAc$ it yields di methyl-anthraquinone [158°] The picric acid compound forms long red needles. Forms a grey compound with nitro anthracene.

[219°] One of the products of the passage of benzyl-mesitylenethrough a red hot tube (Louise, *Bl* [2] 44, 178) Rhomboidal plates, insol cold alcohol, sl sol ether, ligroin, and acetic acid, v sol hot benzene and toluene. Forms small colourless leaflets when sublimed. Br in CS_2 forms a crystallised bromo-derivative. The picric acid compound crystallises in red needles. CrO_3 in HOAc oxidises it to a di-methyl anthraquinone [170°]. Forms a green compound with nitro-anthracene.

Di-methyl-anthracene

Obtained by distilling with zinc dust the tri-ox-di-methyl-anthraquinone derived from *m* xylene carboxylic acid, gallic acid, and H_2SO_4 (Birukoff, *B* 20, 871) Plates. Oxidised by CrO_3 to a di-methyl-anthraquinone [112°]

[218°] Obtained by treating a mixture of toluene (3 pts), CS_2 (3 pts), and chloroform (1 pt) with $AlCl_3$ (2 pts) (Elbs a Wittich, *B* 18, 348). With chromic acid it gives a quinone [162°]. Probably identical with the isomeride [219°]

[203°] From [2 4 1] $C_6H_4Me_2$, CO , C_6H_4 , CO_2H [1 2] by heating with red hot zinc-dust (Gresly, *A* 234, 238) Plates. Possibly identical with the isomeride [220°-226°]

Di-methyl-anthracene

reduction of di-methyl-anthraquinone [183°] with zinc-dust and NH_3 . White plates, with bluish-green fluorescence. Its picrate forms garnet-red needles, decomposed by alcohol (Elbs a Eurich, *B* 20, 1863)

Di-methyl-anthracene

coal tar xylene by chlorination at boiling temperature, and subsequently heating the resulting [3 1] $C_6H_4(CH_3)(CH_2Cl)$ with water at 210° (Van Dorp, *B* 5, 674) White fluorescent plates. Yields on oxidation with chromic acid a quinone [158°]. Br gives a di-bromo di-methyl anthracene [154°]. Perhaps identical with the following isomeride

Di-methyl-anthracene

a C) Occurs in coal-tar (Zincke a Wachen-dorff, *B* 10, 1481) Formed from toluene, $AlCl_3$, and acetylene tetra-bromide (Anschütz, *A* 235, 172) Prepared by acting on toluene with methylene chloride in presence of $AlCl_3$ (Friedel a Crafts, *Bl* [2] 41, 323, *A Ch* [6] 11, 266). Scales. With CrO_3 in HOAc it gives dimethyl-anthraquinone [160°], which forms an orange

solution in H_2SO_4 . The picric acid compound crystallises in slender needles

Di-methyl-anthracene

methyl anthracene dihydride,

$C_6H_4Me \begin{array}{c} \diagup CHMe \\ \diagdown CHMe \end{array} C_6H_4Me$ by distillation over red hot zinc dust (Anschutz, *A* 235, 320), Greenish-yellow laminae (from benzene), m sol benzene, sl sol alcohol. Gives on oxidation di-methyl-anthraquinone [238°]

s Di-methyl-anthracene dihydride $C_{16}H_{16}$, i.e.

$C_6H_4 \begin{array}{c} \diagup CMeH \\ \diagdown CMeH \end{array} C_6H_4$ [181°] From ethylidene bromide, benzene, and $AlCl_3$ (Anschutz, *A* 235, 305) Yellow laminae (from alcohol) Sublimes in yellow needles. V sol benzene, CS_2 , and ether, sl sol cold alcohol and glacial HOAc. Distillation over red hot zinc dust gives anthracene. Oxidation gives anthraquinone. Bromine in HOAc gives $C_6H_4 \begin{array}{c} \diagup CMeBr \\ \diagdown CMeBr \end{array} C_6H_4$, which crystallises from toluene in needles

Picrate $C_{16}H_{16} \cdot C_6H_3(NO_2)_3OH$ [174°]

u-Di-methyl-anthracene dihydride

$C_6H_4 \begin{array}{c} \diagup CH \\ \diagdown CMe_2 \end{array} C_6H_4$ [56°] Formed by the action of HI and red phosphorus on dimethyl-anthron $C_6H_4 \begin{array}{c} \diagup CO \\ \diagdown CMe \end{array} C_6H_4$ at 150° (Hallgarten, *B* 21, 2508) White crystals, sol ether, benzene, and HOAc

[1 2 3 5] [236°] (W), [243°] (G) Obtained by distilling 'ψ cumene phthaloylo' acid $C_6H_4Me_2$, CO , C_6H_4 , CO_2H with zinc dust (Gresly, *A* 234, 239) Formed also by distilling tri-ox-di-methyl anthraquinone [244°] over zinc dust (Wende, *B* 20, 868) Exhibits green fluorescence

Tri-methyl-anthracene $C_{17}H_{14}$, i.e.

Formed by boiling di-*p* xylol ketone $C_6H_4Me_2$, CO , $C_6H_4Me_2$ for six hours, H O being eliminated. Colourless plates, with bluish green fluorescence. Sublimes below 100°, slightly volatile with alcohol. V sl sol cold alcohol, v sol ether. By CrO_3 and acetic acid it is oxidised to tri-methyl anthraquinone [184°] (Elbs a Olberg, *B* 19, 409, *J pr* [2] 35, 483)

Tetra-methyl-anthracene $C_{18}H_{14}$, [c 280°] A small quantity (3 g) is formed from *m* xylene (100 g), Al_2Cl_6 , and acetylene tetrabromide (Anschutz, *A* 235, 173) CrO_3 gives a substance (tetra-methyl anthraquinone?) which forms needles [c 300°]

Tetra-methyl-anthracene (?) [280°] From *o*-xylene, Al_2Cl_6 , and acetylene tetrabromide (Anschutz, *A* 235, 175) Fluorescent needles

Tetra-methyl-anthracene (?) [280°] Formed similarly from *p* xylene (A)

Tetra-methyl-anthracene $C_{18}H_{14}Me_2$, [163°]. Formed by the action of methylene chloride in presence of $AlCl_3$ on *m*-xylene, and in smaller

quantity on ψ -cumene (Friedel & Crafts, *A Ch* [6] 11, 268) Crystallises from benzene Gives a dark red crystalline compound with picric acid Conc H_2SO_4 gives a yellow solution CrO_3 in HOAc oxidises it to tetra methyl anthraquinone [206°]

Tetra-methyl-anthracene dibromide

$C_6H_4Me_4 \begin{smallmatrix} <CBrMe> \\ <CBrMe> \end{smallmatrix} C_6H_4Me_4$ From the corresponding tetra methyl anthracene dihydride by bromination (Anschutz, *A* 235, 321) Yellow needles, decomposes when heated

Tetra methyl-anthracene dihydride

$MeC_6H_4 \begin{smallmatrix} <CMeH> \\ <CMeH> \end{smallmatrix} C_6H_4Me_4$ [171°] Obtained by the action of ethylidene chloride on toluene in presence of $AlCl_3$ (Anschutz, *A* 235, 317) Pale yellow trimetric laminae, $a, b, c = 675, 1, 924$ (from alcohol and HOAc), ν sol benzene, sl sol HOAc, ν sl sol alcohol Distillation over red hot zinc dust gives di methyl anthracene [244°] Oxidation gives di-methyl-anthraquinone [236°]

Picrate $C_{18}H_{12}O_6N_2$ (OH) [165°] Red glistening needles

Hexa-methyl-anthracene $C_{18}H_{12}Me_6$ [c 220°]

One of the products of the action of methylene chloride on ψ -cumene in presence of $AlCl_3$ (Friedel & Crafts, *A Ch* [6] 11, 272) Not volatile at 410° The alcoholic solution gives with picric acid a brownish black pp [203°] Conc H_2SO_4 forms a red solution, becoming colourless after absorbing moisture

DI METHYL ANTHRAMINE $C_{18}H_{12}NMe_2$. *Di methyl anthracylamine* [155°] Formed by heating the methyl hydrate Thin golden plates Soluble in alcohol with a green fluorescence

Salts — $BHCl$ colourless plates, decomposed by water — $B'HCl, PtCl_4$ yellow pp

Methylo iodide $B'MeI$ [215° uncor]

Formed by heating anthramine with methyl iodide at 100° Flat needles, sol hot water, sl sol cold, nearly insol alcohol

Methylo chloride platinum salt

$B'_2Me Cl.PtCl_4$ yellow crystalline pp

Methylo hydrate $B'Me(OH)$ strongly alkaline Formed by the action of Ag_2O on the iodide, on boiling the aqueous solution it decomposes into di methyl anthramine and methyl alcohol (Bollert, *B* 16, 1636)

METHYL-ANTHRANILIC ACID ν AMIDO-TOLUIC ACID

(B 1) METHYL-ANTHRAQUINONE

$C_{18}H_{10}O_2$ ν $C_6H_4 \begin{smallmatrix} <CO> \\ <CO> \end{smallmatrix} C_6H_4Me$ [5 1] Mol w 222 [154°] (Graebe), [167°] (Birukoff), [176°] (Börnstein) Formed by oxidising (B 1)-methyl-anthracene with CrO_3 and HOAc (Birukoff, *B* 20, 2070) Formed also by oxidising

Vol. III

(B 1) methyl anthracene hexahydride (Graebe *A* 242, 256) The same, or the following, methyl anthraquinone is a by product in the preparation of anthraquinone (Wachendorff & Zinke, *B* 10, 1485, Börnstein, *B* 15, 1820) Small needles (from dilute HOAc) ν e sol alcohol and benzene

(B 2) Methyl-anthraquinone

$C_6H_4 \begin{smallmatrix} <CO> \\ <CO> \end{smallmatrix} C_6H_4Me$ [6 2] [163°] (F), [172°] (E), [177°] (Römer & Link, *B* 16, 695)

Formation — 1 By warming an alcoholic solution of (B 2) methyl anthracene with nitric acid, ppg with water, and subliming (O Fischler, *B* 8, 675) — 2 In small quantity by boiling phenyl m -xylyl ketone (Elbs, *J pr* [2] 35, 471) 3 By warming [4 1] $CH_3, C_6H_4, CO, C_6H_4, CO, H$ with H_2SO_4 at 170° for ten minutes (Gresly, *A* 234, 239)

Properties — Yellow needles Sublimes in almost colourless needles ν sol alcohol, benzene, and HOAc (R & L), according to Fischer, however, it is sl sol these solvents Conc H_2SO_4 forms a blood red solution which becomes violet on heating When heated with zinc-dust it yields methyl anthracene [203°] With fuming H_2SO_4 it yields a disulphonic acid, which on fusion with potash forms di oxy methyl anthraquinone (methyl alizarin) [252°] (Fischer)

Isomeride of Methyl anthraquinone ν METHANTHRENE

Di methyl-anthraquinone $C_{18}H_{12}O_2$ ν $C_6H_4 \begin{smallmatrix} <CO> \\ <CO> \end{smallmatrix} C_6H_4Me_2$ [1 2 4] ν [153°] Obtained

by oxidising the corresponding di methyl anthracene [71°] Formed also by heating benzoyl mesitylenic acid $C_6H_3CO, C_6H_4Me, CO, H$ with P_2O_5 and subliming the product (Louise, *A Ch* [6] 6, 193, 228, *Bl* [2] 44, 181) Yellow acicular prisms (from chloroform acetone) or needles (by sublimation) Insol water, sl sol alcohol, sol chloroform and acetone With zinc-dust and KOH it gives an intense red colour This di methyl anthraquinone ought theoretically to be identical with those melting at 180 and 112° (ν infra)

Di methyl anthraquinone $C_{18}H_{12}O_2$ [170°] Obtained by oxidising di methyl anthracene [219°] with CrO_3 in HOAc (Louise, *A Ch* [6] 6, 189, *Bl* [2] 44, 180) Yellow needles (from alcohol) With zinc dust and KOH it gives a characteristic red tint, which disappears on heating

Di methyl anthraquinone

$C_6H_4 \begin{smallmatrix} <CO> \\ <CO> \end{smallmatrix} C_6H_4Me$ [1 3 4] [183°] Obtained by heating o -xylyl phenyl ketone carboxylic acid (o -xylyl- o -benzoic acid) [3 4 1] $C_6H_4Me, CO, C_6H_4, CO, H$ [2] with conc H_2SO_4 By HNO_3 (S G 1 2) at 220° it is oxidised to anthraquinone di carboxylic acid [340°] (Elbs & Eulich, *B* 20, 1361).

Di-methyl-anthraquinone

$C_6H_4 \begin{smallmatrix} <CO> \\ <CO> \end{smallmatrix} C_6H_4Me_2$ [1 2 4] [180°] Formed by heating m -xylyl phenyl-ketone- o -carboxylic acid (m -xylyl- o -benzoic acid) [2 4 1] $C_6H_4Me, CO, C_6H_4, CO, H$ [1 2] with conc H_2SO_4 , the yield is 60 to 70 p c of the theoretical (Gresly, *A* 234, 240, Elbs & Gunther, *B* 20, 1364) Small needles, sl sol benzene

U

and alcohol By dil HNO_3 it is oxidised to anthraquinone *m* di carboxylic acid [above 330°] Reduced by zinc dust and ammonia to a hydrocarbon [85°] which forms with picric acid reddish-brown scales [136°]

Di methyl anthraquinone

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C}_6\text{H}_2\text{Me}_2 \left[\begin{smallmatrix} 1 \\ 6 \end{smallmatrix} \begin{smallmatrix} 2 \\ 5 \end{smallmatrix} \right]$ [118°] Formed by warming $\left[4 \frac{1}{2} \right] \text{C}_6\text{H}_2\text{Me}_2 \cdot \text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H} \left[2 \frac{1}{2} \right]$ with conc H_2SO_4 at 120° (Gresly, *A* 234, 240)

Di methyl anthraquinone

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C}_6\text{H}_2\text{Me}_2 \left[\begin{smallmatrix} 1 \\ 6 \end{smallmatrix} \begin{smallmatrix} 2 \\ 4 \end{smallmatrix} \right]$? [112°] Obtained by oxidising the di methyl anthracene [220°–226°] (Birukoff, *B* 20, 871)

Di methyl anthraquinone

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C}_6\text{H}_2\text{Me}_2$ [162°] Obtained by oxidising di methyl anthracene [216°] (Elbs & Wittich, *B* 18, 348)

Di-methyl anthraquinone

$\text{C}_6\text{H}_2\text{Me} \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C}_6\text{H}_2\text{Me}$ [236°] Formed by oxidation of di methyl anthracene [244°] Pale yellow needles, sl sol HOAc , v sl sol alcohol (Anschutz, *A* 235, 321)

Di-methyl-anthraquinone

$\text{C}_6\text{H}_2\text{Me} \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C}_6\text{H}_2\text{Me}$ [155°] Obtained by oxidising the di methyl anthracene occurring in coal tar xylene (Wachendorff & Zincke, *B* 10, 1482) Small light yellow needles (from dilute alcohol) May be sublimed M sol alcohol, ether, and HOAc

Di-methyl-anthraquinone

$\text{C}_6\text{H}_2\text{Me} \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C}_6\text{H}_2\text{Me}$ [160°] Obtained by oxidising the di-methyl anthracene formed from toluene, methylene chloride, and AlCl_3 (Friedel & Crafts, *A Ch* [6] 11, 266) Forms an orange solution in H_2SO_4 Probably identical with the preceding

Tri-methyl anthraquinone

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C}_6\text{HMe}_2$ [Me Me Me = 1 2 4] [161°] Formed by warming ψ cuminoyl benzoic acid C_6HMe , $\text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$ for a short time with conc H_2SO_4 (Gresly, *A* 234, 240) Needles

Tri-methyl-anthraquinone

$\left[2 \frac{5}{6} \frac{1}{3} \right] \text{C}_6\text{H}_2\text{Me}_2 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C}_6\text{H}_2\text{Me} \left[\begin{smallmatrix} 1 \\ 6 \end{smallmatrix} \begin{smallmatrix} 3 \end{smallmatrix} \right]$ [184°] Formed by oxidation of the tri methyl anthracene obtained from di *p* xylil ketone (Elbs & Olberg, *B* 19, 409)

Di methyl-benzene sulphonic acid v XYLENE SULPHONIC ACID

c-Tri-methyl benzene sulphonic acid
 $C_6H_3Me_3(SO_3H)$ [1 2 3 5] *Hemimellitene sulphonic acid* Formed by sulphonation of hemimellitene (Jacobsen, *B* 15, 1858, 19, 2617) Crystallises from dilute H_2SO_4 in six sided plates or tables (containing aq) — NaA' aq tables, v sol hot, m sol cold, water — $*BaA'$, brittle plates, v sl sol water

Amide $C_6H_3Me_3SO_2NH_2$ [196°] Prisms or needles Less soluble in alcohol than the amide of ψ -cumene sulphonic acid

Isomerides v ψ -CUMENE SULPHONIC ACID and MESITYLENE SULPHONIC ACID

Tetra methyl-benzene sulphonic acid v. DURENE SULPHONIC ACID

Penta-methyl-benzene sulphonic acid
 $C_5Me_5SO_3H$ Obtained by treating penta methyl-benzene with $ClSO_3H$ and treating the product with NaOH to convert the $C_5Me_5SO_3Cl$ first formed into $C_5Me_5SO_3Na$ (Jacobsen, *B* 20, 899) In the action of $ClSO_3H$ on C_5Me_5H a sulphone [98 5°], crystallising from petroleum ether in needles, is also formed The free acid, liberated by shaking the sodium salt with light petroleum and H_2SO_4 , at once undergoes hydrolysis, C_5H_5Me , dissolving in the petroleum

Salts — $A'Na$ tables (from neutral aqueous solution) or plates (from hot, dilute, NaOH), sl sol cold water, m sol hot water, insol cold, dilute NaOH — $A'K$ plates (from hot water) — $A'Ba$ plates, v sl sol hot water — $A'Ca$ plates — $A'Ag$ plates, v sl sol cold, m sol hot, water — $A'Cu$ greenish white tables, sl sol water

Chloride [82°] Plates (from EtOH), or prisms (from Et₂O), v sol EtOH and Et₂O

Amide [186°] Prisms, v e sol hot, m sol cold, EtOH, insol water $KMnO_4$ produces a sulphamic acid [c 265°]

METHYL - BENZGLYCOCYAMIDINE v BENZOREATININE**METHYL-BENZGLYCOCYAMINE v BENZ-UREATIN****TETRA METHYL BENZIDINE v. TETRA-METHYL-DI-*p* AMIDO DIPHENYL****METHYL-BENZYL v PHENYL TOLYL DIKETOONE****METHYL-BENZOIC ACID v TOLUIC ACID**

Di-methyl-benzoic acid $C_6H_4O_2$ *o,s*
 $C_6H_4Me_2CO_2H$ [6 2 1] *m-Xylene o-carboxylic acid* [97°-99°] Formed by fusing potassium *m*-xylene *c*-sulphonate with sodium formate (Jacobsen, *B* 11, 21) Short needles (from water) Forms *m*-xylene when distilled with lime

Di-methyl-benzoic acid
 $C_6H_4Me_2CO_2H$ [4 2 1] *m Xylene o carboxylic acid Xylylic acid Xyloic acid* [126°]. (267°) at 727 mm

Formation.—1 By the oxidation of ψ -cumene by dilute nitric acid, being separated from the accompanying $C_6H_4Me_2CO_2H$ [5 2 1] through the greater solubility of its Ca salt (Fittig & Laubinger, *A* 151, 269) —2 By treating bromo-*m*-xylene with sodium and CO_2 (Kekulé, *A* 187, 186) —3 By warming its nitrile with H_2SO_4 (85 p c) and heating the resulting amide with conc HCl aq at 170° (Birukoff, *B* 20, 871, *A* 240, 246) —4 By heating its diphenylamide

with HCl aq (*v infra*) —5 By decomposing its chloride (*v infra*) with water

Properties — Slender needles (from water) or monoclinic prisms (from alcohol) May be sublimed Almost insol cold water, sl sol hot water, v sol hot alcohol Gives *m*-xylene when heated with lime Chromic acid mixture oxidises it to $C_6H_4Me_2(CO_2H)_2$ [3 1 4]

Salts — CaA' , 2aq monoclinic prisms, v sol water — BaA' , 8aq ? — AgA'

Chloride $C_6H_4Me_2COCl$ [25 5°] (235°) Formed by passing $COCl_2$ into *m*-xylene containing $AlCl_3$, and heating to 100° (Ador & Meyer, *B* 12, 1968)

Amide $C_6H_4Me_2CONH_2$ [180°] Formed by warming the nitrile with H_2SO_4 (85 p c) Formed also by the action of NH_3 , $COCl$ on *m*-xylene in presence of $AlCl_3$ (Gattermann, *A* 244, 58) Formed also by passing gaseous $HCNO$ and HCl gas into *m*-xylene containing $AlCl_3$ on the water bath (Gattermann & Rossolymov, *B* 23, 1196) Long shining needles (from water) Almost insol cold water, v sol alcohol

Anilide $C_6H_4Me_2CONHPh$ [138 5°] Crystals, v sl sol hot water

Diphenylamide $C_6H_4Me_2CONPh_2$ [142°] Formed from *m*-xylene and NPh_2 , $COCl$ in presence of $AlCl_3$ (Lellmann & Bonhöffer, *B* 20, 2120) Monoclinic crystals, v e sol hot alcohol, HOAc, and chloroform, sl sol hot ether, v sl sol hot petroleum ether

Nitrile $C_6H_4Me_2CN$ [25°] (221°) SG 12 9871 (Hinrichsen, *B* 21, 3082) VD 4 64.

Formation.—1 By heating the formyl derivative of *m*-xylydine with zinc-dust, the yield being about 12 p c (Gassioovsky & Merz, *B* 18, 1012) —2 By distilling the corresponding $PO(OC_2H_5)_2$, with $K_2Cr_2O_7$, the yield being 15 p c (Kreysler, *B* 18, 1713) —3 From *m*-xylydine by Sandmeyer's reaction (Bruckoff *B* 20, 871) **Properties** — Triclinic crystals (from dilute alcohol) Volatile with steam Yields benzyl di methyl amine on reduction

Amidoxim $C_6H_4Me_2C(NH)NOH$ [178°] *Xylenylamidoxim* Formed by the action of hydroxylamine on the nitrile at 85° (E Oppenheimer, *B* 22, 2443) White needles, v sol alcohol, ether, chloroform, and hot water, sl sol cold water **Reactions**.—1 EtI acting on its Na derivative forms $C_6H_4Me_2C(NH)NOEt$ which crystallises in white needles, [172°], v sol alcohol, ether, chloroform, benzene, and boiling water, sl sol cold water Excess of HCl converts the ethyl derivative into $C_6H_4Me_2CClNOEt$, a yellow aromatic oil —2 *Chloral* forms a compound $CCl_2CHO(C_6H_4Me_2C(NH)NOH)$ [112°] crystallising in white scales, sl alcohol and ether but decomposed by water and dilute acids 3 $ClCO_2Et$ acting on the amidoxim in chloroform forms $C_6H_4Me_2C(NH)NOCO_2Et$ [143°] which crystallises in white needles, v sol alcohol, ether, and chloroform, sl sol ligroin It is converted by heat into $C_6H_4Me_2C \begin{smallmatrix} N & O \\ \diagdown & / \\ & NH \end{smallmatrix} CO$ which crystallises in needles [182°], v sol alcohol and ether —4 Potassium cyanate acting on the hydrochloride of the amidoxim forms $C_6H_4Me_2C(NOH)NHCO_2NH_4$ [153°] which crystallises from dilute alcohol in white scales, and forms an unstable platinumchloride —5. *Phenyl cyanate* at 100° reacts forming

$C_6H_5Me_2C(OH)NHCO NHPH$ [188°] which crystallises from alcohol in light yellow scales, sol acids, alcohol, ether, chloroform, benzene, and hot water—6 *Phenyl thio-carbimide* at 100° forms $C_6H_5Me_2C(OH)NHOS NHPH$ [150°], sol alcohol, ether, benzene, boiling water, and acids—7 Heating with As_2O_3 forms the azoxim $C_6H_5Me_2C \begin{smallmatrix} \text{N} \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} > CCH_3$ [89°]—

8 *Succinic anhydride* forms the azoxim $C_6H_5Me_2C \begin{smallmatrix} \text{N} \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} > CCH_2CH_2CO_2H$ which forms long white needles, [112°], v sol alcohol, ether, benzene, $CHCl_3$, and hot water, and yields crystalline salts

Acetyl derivative of the *amidoxim* $C_6H_5Me_2C(NOAc)NH_2$ [189°] Small white needles, v sol alcohol and chloroform, sl sol ether (Oppenheimer, B 22, 2445)

Benzoyl derivative of the *amidoxim* $C_6H_5Me_2C(NO_2)NH_2$ [158°] White crystals, v sol alcohol, ether, and chloroform, sl sol water and ligroin Converted by heat into $C_6H_5Me_2C \begin{smallmatrix} \text{N} \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} > CCH_3$, which crystallises in faintly yellow scales, v sol alcohol, ether, and chloroform, volatile with steam (Oppenheimer, B 22, 2444)

Di-methyl benzoic acid $C_6H_5Me_2CO_2H$ [5 2 1] *p* *Xylene carboxylic acid* [132°] (268° ± V)

Formation—1 From bromo-*p* xylene by treatment with $ClCO_2Et$ and sodium amalgam, the resulting ether being then saponified (Jacobsen, B 14, 2111)—2 By oxidation of methyl xylyl ketone $CH_3COCH_2Me_2$ [1 2 5] by dilute HNO_3 or by $KMnO_4$ (Claus, B 18, 1858, 19, 3183)—3 From its amide

Properties—Large needles (from alcohol), v sl sol hot water, v e sol alcohol Volatile with steam Yields $C_6H_5Me(CO_2H)_2$ [2 5 1] on oxidation

Salts— CaA' , 2aq crusts, m sol water— BaA' , 4aq small needles

Amide $C_6H_5Me_2CONH_2$ [186°] Formed by the action of $ClCO_2NH_2$ (or of $HNCO$ and HCl) on *p* xylene in presence of $AlCl_3$ (Gattermann, A 244, 54, B 23, 1199) Colourless needles (from water), m sol hot water, v e sol alcohol

Di-methyl-benzoic acid $C_6H_5Me_2CO_2H$ [3 2 1] *o* *Xylene c* *carboxylic acid* *Hemimellitethylic acid* [144°] Formed by the oxidation of hemimellitene $C_6H_5Me_2$ [3 2 1] by dilute nitric acid (Jacobsen, B 19, 2518) Prisms (from hot alcohol) or plates (from dilute alcohol) Volatile with steam, v sl sol hot water, insol cold water Yields *o*-xylene when distilled with lime CaA' , aq Long prisms, m sol cold water

Di-methyl benzoic acid $C_6H_5Me_2CO_2H$ [4 3 1] *o* *Xylene t* *carboxylic acid* [165°] Obtained by boiling its amide for 2 days with caustic potash solution Formed also, together with the isomeric *m*-xylene *t* *carboxylic acid* [126°] (*u supra*), by oxidising ψ cumene with dilute HNO_3 (Fitting a Laubinger, A 151, 275) Its ether is formed by the action of sodium-amalgam on a mixture of bromo-*o* xylene and $ClCO_2Et$ (Jacobsen, B 17, 2874) Prisms (from alcohol), almost insol cold water, v sl sol boiling water, v e sol alcohol Gives *o* xylene when distilled with lime Gives $C_6H_5Me(CO_2H)_2$

[3 4 1] on oxidation with dilute nitric acid— CaA' , 3aq Needles— BaA' , 4aq Needles, v sol water

Amide $C_6H_5Me_2CONH_2$ [131°] Formed by the action of NH_2COCl on *o* xylene in presence of $AlCl_3$ (Gattermann, A 244, 52) Long shining needles (from water) The amide obtained from *o* xylene, gaseous cyanic acid, HCl , and $AlCl_3$, melts at 165° (Gattermann a Rossolymo, B 22, 1199)

Diphenylamide $C_6H_5Me_2CONPh_2$ [136°] From NPh_2COCl , *o* xylene, and $AlCl_3$ (Lellmann a Bonhoffer, B 20, 2119) Small prisms v sol hot alcohol, sl sol ether and ligroin

Nitrile $C_6H_5Me_2CN$ (232°) VD 4 61 Formed by fusing potassium *o* xylene sulphonate with KCy (Jacobsen, B 11, 23) Formed also by heating the corresponding xylenyl phosphate $PO(OC_6H_5Me_2)_3$ with KCy , the yield being 20 p c (Kreysler, B 18, 1711) Liquid, miscible with alcohol and ether

Di-methyl-benzoic acid $C_6H_5Me_2CO_2H$ [5 3 1] is described as *MESITYLENIC ACID*

Di-methyl-benzoic acid $C_6H_5Me_2CO_2H$? *Lauroxylic acid* [155°] Produced by the action of dilute nitric acid on laurene $C_{11}H_{18}$ (Fitting, Köbrich, a Jilke, A 145, 151) Hard nodules (from alcohol) Nearly insol cold, sl sol boiling, water, v sol alcohol Yields acetic acid on oxidation with chromic acid mixture— BaA' , 4aq Concentrically grouped needles, v sol water— CaA' , 4aq— AgA' White pp, may be crystallised from water

Tri-methyl-benzoic acid ψ *CUMINIC ACID* Another tri methyl-benzoic acid, *Hemimellitene carboxylic acid*, is described as *c-CUMINIC ACID*

Tetra-methyl-benzoic acid $C_6HMe_4CO_2H$ [5 4 3 2 1] [165°] (G), [150°] (C) (c 270°) Formed by oxidising penta methyl benzene, dissolved in benzene, with dilute nitric acid (Gottschalk, B 20, 3286) Formed also by oxidising tetra methyl-phenyl methyl ketone or tetra methyl phenyl acetic acid with $KMnO_4$ (Claus, J pr [2] 38, 234) Needles (G), m sol hot water, v e sol alcohol, ether, benzene, CS_2 , and chloroform (C) Its alkaline salts are very soluble The Ag salt is v sl sol water The cupric salt forms light-green plates— BaA' , 2aq Plates or nodules, v sol water and alcohol (G)— BaA' , 6aq (C)— CaA' , 3aq (G)— NaA' 3aq

Tetra-methyl-benzoic acid $C_6HMe_4CO_2H$ [6 4 3 2 1] Formed by oxidising the corresponding $C_6HMe_4CO_2CH_3$ with $KMnO_4$ (Claus a Foecking, B 20, 8103) Yellow liquid, not solidified at 0°

Tetra-methyl-benzoic acid $C_6HMe_4CO_2H$ [6 5 3 2 1] [109°] (C a F), [112°] (G) Formed by oxidising the corresponding $C_6HMe_4CO_2CH_3$ with $KMnO_4$ (Claus a Foecking, B 20, 8103) Formed also by boiling its amide for several days with alcoholic potash (G) Plates

Amide $C_6HMe_4CONH_2$ [173°] From durenene, $ClCONH_2$, and $AlCl_3$ (Gattermann, A 244, 55) Shining plates (from dilute alcohol)

Tetra-methyl-benzoic acid $C_6HMe_4CO_2H$ [179°] From durenene $COCl_2$, and $AlCl_3$, the product being decomposed by water (Jacobsen, B 22, 1223) Also from $C_6HMe_4CO_2C_2H_5$ and $KMnO_4$ (Meyer a Ador, J 1879, 562) Must be identical with one of the three preceding acids,

probably with that of Gottschalk Large plates (from dilute alcohol), v sl sol cold water Volatile with steam May be distilled Conc HClAq at 210° yields durenene and CO₂—CaA', Short prisms, sl sol hot water—BaA', 4aq Small plates (from hot water)

Methyl ether C₆HMe, CO₂Me [59°] (269° v) Plates (Jacobsen, B 22, 1223) Saponified by alcoholic potash at 210°

Nitrile C₆HMe, CN [77°] Formed by distilling tetra methyl benzoic acid with PbC₂ (Jacobsen, B 22, 1224) Needles, v e sol alcoh. Split up by HCl at 215° into durenene and CO₂. A crystalline nitrile C₆H(CH₃), CN [69°], (260°), probably identical with the last is formed by the isomeric change of the carbamine derived from duridine (q v) by distillation It is very stable towards HCl, by which it is not saponified to the acid, but at 250° it decomposes with formation of tetra methyl benzene (Hofmann, B 17, 1914)

Amide C₆HMe, CONH₂ [173°] Formed by passing gaseous cyanic acid and HCl into durenene containing AlCl₃ at 100° (Gattermann a Rossolymo, B 23, 1199) It is probably the amide of the acid [179°], but has not been fully examined

Penta-methyl-benzoic acid C₆Me₅CO₂H [210 5°] Formed from penta methyl benzene, COCl₂, and AlCl₃ at 0°, after a fortnight the product is exposed to moist air and then treated with water (Jacobsen, B 22, 1220) Needles (from water) or prisms (from 70 p.c alcohol), v sl sol cold, sl sol hot, water, v e sol hot alcohol Volatile with steam May be distilled With H₂SO₄ it yields C₆Me₅ and c durenene (prehnitene) HNO₃ forms di nitro c durenene Fuming HClAq at 200° yields CO₂ and penta-methyl-benzene—CaA', Prisms, m sol water—BaA', 2aq Plates, sol hot water

Methyl ether MeA' [67 5°] (300° v) Plates, v sol alcohol

Amide C₆Me₅CONH₂ [206°] From C₆HMe₅, chloro formamide, and AlCl₃ Plates, sl sol hot, v sl sol cold, water

Nitrile C₆(CH₃), CN [170°] (J), [168°] (H) (292°) (H), (295°) (J) Formed from the carbamine C₆Me₅NC by intra-molecular trans formation by heating it a few degrees above its melting point (Hofmann, B 18, 1825) Large white needles, sol alcohol and ether, insol water It is remarkably stable, and could not be saponified by treatment with acids or alkalis. By heating with HI at 220°–230° it yields penta-methyl benzene, NH₃, and CO₂. Conc HClAq at 215° also yields C₆HMe₅.

METHYL-BENZOIC ALDEHYDE v TOLUIC ALDEHYDE

Di-methyl-benzoic aldehyde C₆H₂Me₂CHO [4 2 1] m *Xylobenzaldehyde* *Xylylic aldehyde*. [–8°] (216°) Formed by oxidising di methyl-benzyl alcohol with K₂Cr₂O₇ and H₂SO₄ (Hinrichsen, B 21, 3085, 22, 121) Separated by K₂CO₃. Colourless oil, volatile with steam HNO₃ oxidises it to di-methyl benzoic acid [126°]

Di-methyl-benzoic aldehyde C₆H₂Me₂CHO [5 3 1] (221°) Formed from mesitylene by treatment in CS₂ with CrO₃Cl₂, followed by water (Etard, C. R 97, 909) The yield is almost the theoretical quantity Yields mesitylene acid on oxidation.

Tri-methyl-benzoic aldehyde *Phenyl hydrazide* Me₃C₆H₂CH N₂HPH [129°] Formed by the action of tri methyl benzoic aldehyde on a solution of phenyl hydrazine in dilute HOAc (Rudolph, A 248, 100) Colourless needles, very sensitive to light, v sol ether, hot alcohol, and petroleum ether

DI-METHYL-BENZOIN C₆H₂O₂ v e [4 1] C₆H₂Me CO CH(OH) C₆H₂Me [4] [89°] p *Toluoin* Prepared by boiling 10 pts of p toluic aldehyde (from p xylene) with 2 pts of KCy and 30 pts of 50 p.c alcohol, and shaking the mass, after cooling, till the yellow product separates (Sterlin, B 22, 380, cf Grimaux a Lauth, B. 7, 233) Pale yellow prisms (from dilute alcohol), sl sol hot water, v sol alcohol, ether, and benzene Fuming H₂SO₄ gives a beautiful green colour

Acetyl derivative C₆H₂AcO₂ [100°] White crystals, v sol alcohol and ether
Benzoyl derivative C₆H₂BzO₂ [119°] White crystals, v sol alcohol and ether

METHYL BENZONITRILE v *Nitrile* of TOLUIC ACID

Di-methyl-benzonitrile v *Nitrile* of Di-METHYL BENZOIC ACID

METHYL-BENZOPHENONE v PHENYL TOLYL KETONE

Di-methyl-benzophenone v PHENYL XYLIL KETONE and Di TOLYL KETONE

TRI-METHYL-BENZOQUINONE CARBOXYLIC ACID v ψ-CUMOQUINONE CARBOXYLIC ACID

METHYL-BENZOYL-ACETIC ACID v. a BENZOYL PROPIONIC ACID

Di-methyl-benzoyl-acetic acid [5 2 1] C₆H₂Me₂CO CH₂CO₂H *Xylyl methyl ketone carboxylic acid* [132°] Formed, together with di methyl benzoic acid, by oxidising xylyl ethyl ketone with very dilute KMnO₄ (Claus a Fickert, B 19, 3183) Needles, sl sol water, v sol alcohol and ether—NaA' aq crusts, v sol water—CaA', 2½aq needles, sl sol cold water—BaA', 4aq prisms, sl sol cold water—AgA'

TETRA-METHYL-BENZOYL-BENZOIC ACID C₆HMe₄CO₂C₆H₂CO₂H [2 1] *Duroyl-benzoic acid* [c 260°] Formed by heating phthalic anhydride with durenene in presence of AlCl₃ (Friedel a Crafts, A Ch [6] 14, 454, C R 92, 833) Insol water, v sol alcohol, ether, and benzene May be crystallised from HOAc The Pb, Cu, and Ag salts are insol water—KA' minute needles, v sol cold water—NaA', v sl sol alcohol—NH₄A' needles—BaA', aq groups of needles, v sl sol water—CaA', aq needles, v sl sol water

METHYL-BENZOYL-ETHYL-HYDROXYLAMINE v HYDROXYLAMINE DERIVATIVES

TRI-METHYL-BENZOYL-PROPIONIC ACID v ψ CUMYL ETHYL KETONE-CARBOXYLIC ACID

METHYL-DIBENZYL v PHENYL TOLYL-ETHANE

METHYL-BENZYL-ACETIC ACID v PHENYL-250 BUTYRIC ACID

DI-METHYL-BENZYL ALCOHOL C₆H₂O v e [4 2 1] C₆H₂Me₂CH₂OH *Xylyl alcohol* [22°] (232°) Formed by adding KNO₃ to a solution of dimethyl benzyl amine sulphate (Hinrichsen, B 21, 3085) Colourless liquid, with aromatic odour, volatile with steam Oxidised by chromic acid mixture to di-methyl-benzoic aldehyde

Acetyl derivative $C_6H_5MeCH_2OAc$ (230°–234°).

Benzoyl derivative $C_6H_5MeCH_2OBz$ (333°)

Yellow oil (Hinrichsen, *B* 22, 123)

Penta-methyl-benzyl alcohol $C_6H_5MeCH_2OH$ *Mesityl alcohol* [160.5°] Obtained by saponifying its acetyl derivative with alcoholic potash (Jacobsen, *B* 22, 1217) Dimeric prisms, insol water, v sol alcohol

Acetyl derivative $C_6H_5MeCH_2OAc$ [85°] (310°) Obtained by the action of KOAc and HOAc on the chloride $C_6H_5MeCH_2Cl$, which is got by heating hexamethyl benzene with PCl_5 at 140° (Jacobsen) Plates or prisms (from alcohol), v sol ether, m sol alcohol at 0°, insol water

METHYL-BENZYL-AMINE

[2 1] $C_6H_5MeCH_2NH_2$ *o-Tolyl methyl-amine Xylylamine* (202°) Formed by heating methyl-benzyl phthalamide (derived from ω bromo-o xylene) with conc $HClAq$ in sealed tubes at 200° (Strassmann, *B* 21, 577) Liquid, which absorbs moisture and CO from the air— $B_2H_3PtCl_6$, yellow needles— $BHCl$ needles (from alcohol)—Picrate $B'C_6H_5N_2O_6$, long yellow needles, decomposing above 170°

Acetyl derivative $C_6H_5MeCH_2NHAc$ [69°] Formed by heating the hydrochloride with NaOAc and Ac_2O Crystallises from alcohol

m Methyl-benzyl-amine

[3 1] $C_6H_5MeCH_2NH_2$ (202°) Formed by heating ω bromo m xylene with potassium phthalamide, and decomposing the product with conc $HClAq$ at 190° (Bromme, *B* 21, 2700) Colourless liquid, miscible with alcohol and ether Absorbs CO_2 from the air— $BHCl$ needles $B_2H_3PtCl_6$, [212°] Golden plates—Sulphate [248°]— $B_2H_3C_2O_4$, [172°] Plates, v sol water—Picrate [156°]

Acetyl derivative $C_6H_5MeCH_2NHAc$ (235°–240°) Oil

Benzoyl derivative $C_6H_5MeCH_2NHBz$ [69°] White plates (from alcohol), v sol chloroform, HOAc, and benzene

p Methyl-benzyl-amine

[4 1] $C_6H_5MeCH_2NH_2$ Formed by treating an alcoholic solution of the amide of thio p toluo acid with zinc and $HClAq$ (Paterno a Spica, *B* 8, 441)

m (?) Methyl-benzyl-amine $C_6H_5MeCH_2NH_2$ *Xylylamine* (196°) Formed, together with di methyl di benzyl amine and tri methyl tri benzyl amine by heating ω chloro xylene with alcoholic NH_3 at 116° (Pieper, *A* 151, 129) Oil, smelling like herring brine Is either the m-compound or a mixture Lighter than water Absorbs CO_2 from the air— $BHCl$ [185°] Needles, v sol water and alcohol— $B_2H_3PtCl_6$

Di m (?) methyl-di-benzyl-amine $C_6H_5MeCH_2NH_2$ Formed as above (Pieper) Oil smelling like herring brine Lighter than water Decomposes above 210°— $BHCl$ [198°] Needles, sl sol cold water, v sol hot water and alcohol— B_2H_3Br [196°]

Tri m (?) methyl-tri-benzyl-amine $C_6H_5MeCH_2NH_2$ Formed as above (Pieper) Oil, sl sol alcohol Cannot be distilled With bromine water it yields $(C_6H_5MeCH_2)_3NH$ and C_6H_5MeCHO — $BHCl$ [212°] (P), [204°] (Jannasch, *A* 142, 803) Needles, sl sol cold alcohol, insol water and ether Heated in a

current of dry HCl it yields $(C_6H_5MeCH_2)_3NH$ and $C_6H_5MeCH_2Cl$ — $B'NO_3$, [122°] (J)

Di methyl-benzyl-amine $C_6H_5MeCH_2NH_2$ [4 2 1] $C_6H_5MeCH_2NH_2$ (219°) *Xylyl-methyl-amine Xylobenzyl amine* Formed by reducing with sodium the nitrile of the corresponding di methyl benzoic acid dissolved in alcohol (Hinrichsen, *B* 21, 3083, 22, 122) Liquid, sl sol water, v sol alcohol and ether Readily absorbs CO_2 and moisture from the air Nitrous acid converts it into the corresponding alcohol— $BHCl$ [210°] Needles or plates— $B_2H_3PtCl_6$, [228°]— $B_2H_3HgCl_2$, [205°]—Nitrate [158°]—Sulphate [254°]—Picrate [223°]— $B'CdI_2$ — $B'H_2CdI_2$

Benzoyl derivative $C_6H_5MeCH_2NHBz$ [98°] Needles, v sl sol water, v e sol alcohol and benzene

Di-methyl-benzyl amine v. BENZYL DI METHYL AMINE

METHYL-BENZYL ANILINE

$C_6H_5NMeCH_2Ph$ (306°) (N), (above 360°) (S) From methyl aniline and benzyl chloride (Noelting, *J* 1883, 702, Stebbins, *A C J* 7, 42). Pale yellow oil

p METHYL-BENZYL-BENZOIC ACID

$C_6H_5MeCH_2CO_2H$ [4 1] $C_6H_5MeCH_2CO_2H$, CO_2H [134°] Formed from $C_6H_5MeCO_2C_6H_5$, CO_2H by reducing with zinc dust and ammonia, filtering, diluting with water, adding HCl , dissolving the pp in NH_4Cl , and re ppg with acid (Gresly, *A* 234, 235) Long needles (from alcohol), v sol alcohol, HOAc, and benzene, almost insol water— BaA_2 plates, v sol water

Di-methyl benzyl benzoic acid $C_6H_5MeCH_2CO_2H$ [4 2 1] $C_6H_5MeCH_2CO_2H$, CO_2H [121°] [158°] Obtained by reducing $C_6H_5MeCO_2C_6H_5$, CO_2H with zinc dust and ammonia (Gresly, *A* 234, 237) Small needles (from alcohol)— BaA_2 , aq Plates (from dilute alcohol), sl sol water

METHYL-BENZYL BROMIDE v. o BROMO

XYLENE

DI METHYL-BENZYL CARBAMIC ETHER

$C_6H_5MeCH_2NHCO_2Et$ [6 4 2 1] $C_6H_5MeCH_2NHCO_2Et$ *Mesityl carbamic ether* [62°] From mesidine and $ClCO_2Et$ (Eisenberg, *B* 15, 1016) Long needles (from water) Volatile with steam

METHYL-BENZYL-CARBINOL v. PHENYL-

iso PROPYL ALCOHOL

PENTA-METHYL-BENZYL CHLORIDE

$C_6H_5MeCH_2Cl$ [99°] (c 285°) Formed by heating C_6H_5Me , (40 g) with PCl_5 (50 g) at 140° (Jacobsen, *B* 22, 1217) Plates (from alcohol ether), v e sol ether, sl sol alcohol

TRI METHYL BENZYL CYANATE

[6 4 2 1] $C_6H_5MeCH_2CO$ (219°) From tri methyl-benzyl carbamic ether and P_2O_5 (Eisenberg, *B* 15, 1017) Pungent liquid

METHYL-BENZYL GLYOXIM v. BENZYL-

METHYL GLYOXIM

DI- ω METHYL DI-BENZYLIDENE-ETHYL-

ENE DIAMINE $C_6H_5MeCH_2N_2$ + $C_6H_5MeCH_2N_2$ [c 104°] Formed by heating ethylene diamine (1 mol) with acetophenone (2 mols) to 120° White needles V sol alcohol and benzene, sl sol ether It is readily decomposed into its constituents, especially by acids (Mason, *B* 20, 273)

METHYL BENZYL KETONE v. BENZYL-METHYL-KETONE.

Methyl benzyl diketone $C_{11}H_{10}O_2$ *ze* $CH_3COCOCH_2C_6H_5$ (176°) SG $\frac{1}{2}$ 10721 This ketone is formed by distilling its monoxim $CH_3COC(NO)CH_2C_6H_5$ with $FeCl_3$ and dilute HCl (H Müller a Pechmann, B 22, 2133) Thick yellow oil, smelling like honey.

Di-phenyl-dihydrazide $CH_3C(N,HPH)CH_2C_6H_5$ [173°] Almost colourless flat silky needles

Mono oxim $CH_3COC(NO)CH_2C_6H_5$, **Isonitroso benzyl acetone** [81°] Formed by the action of nitrous acid on barium benzyl-acetoacetate (Ceresole, B 15, 1876, 3072, 16, 886) Needles, insol ligroin May be sublimed Dissolves in aqueous alkalis forming yellow solutions With $NaOEt$ and benzyl chloride it gives $CH_3COC(NOCH_2Ph)CH_2C_6H_5$, a thick yellow oil, volatile with steam

Di-oxim $CH_3C(NO)C(NO)CH_2C_6H_5$, **Methylbenzylacetoximic acid** [181°] Formed by adding an alcoholic solution of hydroxylamine hydrochloride to an alcoholic solution of the mono-oxim (Schramm, B 16, 181, 2185) Small needles With Ac_2O it yields a di acetyl derivative $CH_3C(NOAc)C(NOAc)CH_2C_6H_5$ [80°]

METHYL-BENZYL MALONIC ACID

BENZYL-METHYL-MALONIC ACID

o METHYL-BENZYL-PHTHALAMIC ACID

$C_{11}H_{11}NO_3$ *ze*

[1 2] $C_6H_4MeCH_2NHCOCH_2CO_2H$ [2 1] *o* **Xylyl phthalamic acid** [156°] Formed by boiling *o* methyl-benzyl phthalimide with aqueous $NaOH$ and ppg the solution with HCl (Strassmann, B 21, 576) Slender needles — AgA'

m-Methyl-benzyl-phthalamic acid

[1 3] $C_6H_4MeCH_2NHCOCH_2CO_2H$ [2 1] [131°] Formed in like manner from *m* methyl benzyl-phthalimide (Bromme, B 21, 2700) Slender needles (from hot alcohol) — AgA' *v* sol boiling water

o METHYL-BENZYL-PHTHALIMIDE

[1 2] $C_6H_4MeCH_2N<\begin{smallmatrix} CO \\ CO \end{smallmatrix}>C_6H_4$ [149°] Obtained by heating *o* bromo-*o*-xylene with potassium phthalimide at 200°, the yield being 76 p.c. of the theoretical amount (Strassmann, B 21, 576) White hexagonal crystals (from alcohol), insol water With conc $HClAq$ at 200° it forms methylbenzyl amine (202°) Aqueous $NaOH$ converts it into *o* methyl benzyl-phthalamic acid

m Methyl-benzyl-phthalimide

[1 3] $C_6H_4MeCH_2N<\begin{smallmatrix} CO \\ CO \end{smallmatrix}>C_6H_4$ *m*-Xylyl-phthalimide [118°] Formed in like manner by heating *o* bromo-*m*-xylene with potassium phthalimide at 190° (Brömme, B 21, 2700) Slender hexagonal needles (from hot alcohol), *v* sol ether, chloroform, and alkalis

METHYL-BENZYL-PIPERIDINE v BENZYL-METHYL-PIPERIDINE

METHYL BENZYL SULPHIDE $C_{11}H_{10}S$ *ze* $CH_3SCH_2C_6H_5$ (195°-198°) Formed by heating benzyl chloride with $Pb(SMe)_2$ at 100° (Obermeyer, B 20, 2926)

o Methyl-benzyl thiocarbimide C_8H_9NS *ze*, [2 1] $C_6H_4MeCH_2NCS$ *o* **Xylyl thiocarbimide** (256°) Formed by boiling an ethereal solution of *o*-methylbenzyl-amine with CS_2 and $HgCl_2$

(Strassmann, B 21, 578) Oil, smelling strongly like horse radish

Di-methyl-benzyl thiocarbimide $C_{10}H_{11}NS$ *ze* [4 2 1] $C_6H_4Me_2CH_2NCS$ **Xylobenzyl mustard oil** Formed by heating the corresponding urea ($C_6H_4Me_2CH_2NH_2$)CO with syrupy phosphoric acid (Hinrichsen, B 22, 123)

METHYL-BENZYL-THIO-UREA

$CH_3NHCSNHCH_2C_6H_5$ [74°] Formed by exposing an alcoholic solution of benzylamine mixed with methyl thiocarbimide for some days to the air (Dixon, C J 55, 619) White octahedra, *v* sol hot benzene and hot alcohol, *m* sol ether Gives a black pp with ammoniacal $AgNO_3$, but the aqueous or alcoholic solution is not desulphurised by prolonged boiling with alkaline lead tartrate

Methyl di-benzyl ψ thio-urea v Di BENZYL

METHYL- ψ -THIO UREA

o-Methyl-benzyl-thio-urea C_8H_9NS *ze*

[2 1] $C_6H_4MeCH_2NHCSNH_2$ *o* **Xylyl thio urea** [167°] Formed by evaporating a solution of potassium sulphocyanide and *o* methyl benzyl amine hydrochloride, and heating the residue to 140° (Strassmann, B 21, 578) White needles (from water), *m* sol hot water Turns red in air

m Methyl-benzyl-thio-urea

[3 1] $C_6H_4MeCH_2NHCSNH_2$ [112°] Prepared in the same way as the preceding body, using [3 1] $C_6H_4MeCH_2NH_2$ (Bromme, B 21, 2700)

Di m methyl-di-benzyl-thio-urea $C_{11}H_{12}N_2S$ *ze* ($C_6H_4MeCH_2NH_2$)CS [97°] Prepared by boiling *m* methylbenzyl amine with alcoholic CS_2 (B) Needles, insol water, acids, and alkalis

Tetra methyl-di-benzyl thio-urea $C_{15}H_{18}N_2S$ *ze* ($C_6H_4Me_2CH_2NH_2$)CS **Dizylobenzylsulphourea** [177°] From (4, 2, 1) di methylbenzyl amine and alcoholic CS_2 (Hinrichsen, B 22, 123) Glittering needles (from hot alcohol)

o METHYL-BENZYL-UREA $C_8H_9N_2O$ *ze*

[2 1] $C_6H_4MeCH_2NHCONH_2$ *o*-Xylyl urea [173°] Formed from *o* methylbenzyl amine sulphate and potassium cyanate (Strassmann, B 21, 578) Radiating moss like crystals (from alcohol), insol water

m Methyl-benzyl-urea

[3 1] $C_6H_4MeCH_2NHCONH_2$ [148°] Long needles from alcohol (Brömme, B 21, 2700)

Di-m-methyl-di-benzyl-urea

($C_6H_4MeCH_2NH_2$)CO [137°] Formed from *m* methylbenzyl-amine and $COCl_2$ in ethereal solution (B) Slender needles (from alcohol or ether)

Di-methyl-benzyl-urea $C_{11}H_{12}N_2O$ *ze*

[4 2 1] $C_6H_4Me_2CH_2NHCONH_2$ *m* **Xylobenzyl-urea** [184 5°] Formed by mixing concentrated solutions of (4, 2, 1) di methylbenzyl amine hydrochloride and potassium cyanate (Hinrichsen, B 22, 122) Slender needles (from alcohol), *m* sol water from which it separates as a flocculent pp

METHYL-BISMUTHINE v Bismuth methide under BISMUTH, ORGANIC DERIVATIVES

METHYL BORATES

Tri-methyl-borate Me_3BO_3 (72°) (E a B), (65°) (S) SG $\frac{1}{2}$ 955 (E a B), 940 (S) VD 3 66 (E a B) Prepared by heating B_2O_3 with methyl alcohol at 100° in sealed tubes, and distilling The distillate is freed from $MeOH$ by shaking with conc H_2SO_4 , and the upper

layer is then rectified (Schiff, *Bl* [2] 5, 372, 6, 36) Formed also by the action of BCl_3 on dry methyl alcohol, the upper layer of the product being rectified (Ebelmen a Bouquet, *A Ch* [3] 17, 59, A 60, 251) Colourless mobile liquid, sol alcohol and ether Burns with a green flame (greener than that of Et_2BO) Decomposed by water into boric acid and MeOH

Methyl metaborate MeBO A thick liquid, formed by heating Me_2BO_3 with B_2O_3 When heated, it begins to decompose at 160° giving off Me_2BO_3 , and at 250° there remains a mass of the composition MeB_2O_5 , which becomes vitreous on cooling

An acid methyl borate $\text{Me B}_2\text{O}_5$ was described by Ebelmen (*A Ch* [3] 16, 17) as obtained by treating B_2O_3 with dry MeOH , and as being a vitreous mass, readily decomposed by water into boric acid and MeOH It was probably a mixture of Me_2BO_3 and MeBO

METHYL-BORNYL UREA v **BORNYL-METHYL UREA**

TRI-METHYL-BRAZILIN $\text{C}_6\text{H}_{11}\text{Me}_3\text{O}_3 \cdot \frac{3}{2}\text{aq}$ Formed in the preparation of tetra methyl brazilin (v *infra*) Crystalline, sol dilute alcohol Its solution in aqueous NaOH is colourless and gives a brown pp with FeCl_3

Acetyl derivative $\text{C}_6\text{H}_{10}\text{AcMe}_2\text{O}_3$ [97°]

Tetra-methyl-brazilin $\text{C}_6\text{H}_{10}\text{Me}_4\text{O}_4$ [139°] Formed by the action of NaOEt and MeI on brazilin (Schall a Dralle, *B* 20, 3365, 21, 3009) Snow white crystals Bromine in HOAc forms $\text{C}_6\text{H}_8\text{Br}_2\text{Me}_2\text{O}_4$ [181°] and crystalline di bromo tetra methyl brazilin dibromide $\text{C}_6\text{H}_8\text{Br}_2\text{Me}_2\text{O}_4$

METHYL-BROMACETOL v *aa* **DI BROMO-IRAPANE**

METHYL BROMIDE CH_3Br *Bromo methane* Mol w 95 (45°) SG $\frac{4}{8}$ 1.7331, $\frac{12}{23}$ 1.7235 (Perkin), $\frac{8}{8}$ 1.732 (Merrill) VD ($H=1$) 95 MM 4.644 at 15° (Perkin, *C J* 45, 454) HFp 14,790 HFv 14,210 (Thomsen) SV 55.7 (Lossen, *A* 254, 68)

Preparation—Methyl alcohol (800 grms) and amorphous phosphorus (133 grms) are put into a retort Bromine (800 grms) is slowly run in After some hours the retort is heated and the product condensed in a receiver surrounded by a freezing mixture It is washed with dilute potash, dried over calcic chloride and distilled (Merrill, *J pr* 126, 296, cf Pierre, *J Ph* [3] 13, 156, Bunsen, *A* 46, 44)

Properties—Colourless, mobile liquid, with burning taste and pleasant smell resembling chloroform Burns with greenish brown smoky flame Miscible with alcohol, ether, chloroform, and CS_2 Poured into cold water a white ice like mass is formed It is approximately CH_3Br , 20aq At 5° it begins to split up with evolution of methyl bromide gas

METHYL-BROMO-ACETOACETIC ETHER v **BROMO ACETO-ACETIC ACID**

METHYL-BROMO-ACETOL v **DI BROMO PROPANE**

METHYL α -BROMO-ALLYLOXIDE $\text{C}_3\text{H}_5\text{BrO}$ v $\text{CH}_2\text{OCH}_2\text{CBrCH}_3$ (116°) SG $\frac{12}{13}$ 1.35 Formed by the action of NaOH on $\text{CH}_3\text{OCH}_2\text{CHBrCH}_3$ (Henry, *B* 5, 455)

METHYL BROMO-ALLYL SULPHIDE $\text{C}_3\text{H}_5\text{BrS}$ v $\text{CH}_3\text{SCH}_2\text{CH}_2\text{CHBr}$ Formed by heating $\text{Pb}(\text{SMe})_2$ with *s*-tri-bromo propane in

ethereal solution at 150° (Obermeyer, *B* 20, 2925) Decomposes at 120° – 130° Combines with Br (1 mol)

METHYL-BROMO-AMINE v **METHYLAMINE**

METHYL-DI-BROMO-ANTHRACENE v **LI-BROMO METHYL ANTHRACENE**

METHYL-DI-BROMO ATROLACTIC ACID v **DI BROMO OXY-TOLYL PROPIONIC ACID**

METHYL BROMO-BUTYL KETONE v **ACETYL BUTYL BROMIDE**

TRI METHYL-BROMO-ETHYL AMMONIUM BROMIDE v **TRIMETHYLAMINE bromo-ethyl bromide**

METHYL-BROMO ISATIN v *Methyl derivative of Bromo ISATIN*, p 71

METHYL BROMO ISATOYD v *Bromo methyl-isatoyd*, p 71

METHYL BROMOPROPYL KETONE

$\text{CH}_3\text{COCH}_2\text{CH}_2\text{CH}_2\text{Br}$ *Acetyl propyl bromide*. (118°) at 90 mm (P), (106°) at 60 mm (L)

Formed by treating acetyl propyl alcohol (q v) with a saturated aqueous solution of HBr (Colman a Perkin, jun, *C J* 55, 357, Lipp, *B* 22, 1196) Colourless mobile liquid with penetrating odour Turns brown in light Sl sol cold water, quickly decomposed by hot water, dissolving as acetyl propyl alcohol Forms a crystalline compound with NaHSO_4 , NaOEt and KOH act on it, forming a light ethereal oil $\text{C}_6\text{H}_8\text{O}$ (113°), probably methylene furfuran tetrahydride

METHYL BROMO-STYRENE v **BROMO TOLYLETHYLENE**

METHYL BRUCINE v *Methylo-compounds of BRUCINE*, vol 1 p 637

METHYL BUTENYL TRICARBOXYLIC ACID v **PENTANE TRICARBOXYLIC ACID**

METHYL ISOBUTYL ACETAL v **ALDEHYDE**

METHYL-BUTYL-ACETIC ACID v **HEPTOIC ACID**

Methyl-di-butyl acetic acid v **HENDECIOIC ACID**

METHYL-BUTYL-ACETYLENE v **HEPTENF**

METHYL-ISOBUTYL ANILINE $\text{C}_6\text{H}_5\text{N} \cdot \text{C}_4\text{H}_8\text{NMeCH}_2\text{Pr}$ (235°) (Noelting, *J* 1883, 702)

METHYL ISOBUTYL-BENZENE v **ISOBUTYL TOLUENE**

METHYL-BUTYL-CARBINOL v **HEXYL ALCOHOL**

Di methyl butyl-carbinol v **HEPTYL ALCOHOL**

METHYL ISOBUTYL CARBONATE $\text{C}_4\text{H}_9\text{O}_2$ v $\text{CH}_3\text{O CO OC}_4\text{H}_9$ (143.6° cor) SG $\frac{12}{13}$ 0.95 (Rose, *A* 205, 230)

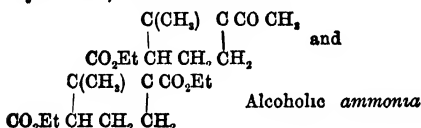

DI-METHYL-BUTYLENE-DIKETONE $\text{C}_6\text{H}_8\text{O}_2$ v $\text{CH}_3\text{COCH}_2\text{CH}_2\text{CH}_2\text{COCH}_3$

Di-acetyl butane (44°) Obtained by heating its dicarboxylic ether with NaOMe in MeOH (Marshall a Perkin, jun, *C J* 57, 241) Crystalline mass, sl sol water, v sol other menstrua Combines with NaHSO_4 Reacts with phenylhydrazine and with hydroxylamine Boiling alcoholic potash condenses it forming methylpenta methenyl trihydride methyl ketone $\text{CH}_3\text{C} \begin{smallmatrix} \diagup \text{C}(\text{COCH}_3) \\ \diagdown \end{smallmatrix} \text{CH}_3$

DI-METHYL-BUTYLENE-DIKETONE CARBOXYLIC ETHER $\text{C}_6\text{H}_8\text{O}_4$ v $\text{CH}_3\text{COCH}_2\text{CH}_2\text{CH}_2\text{CH}(\text{CO}_2\text{Et})\text{COCH}_3$

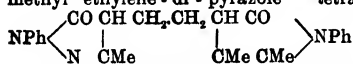

di-acetyl n valeric ether (195°–200°) at 100 mm. Obtained by distilling the corresponding di-carboxylic ether (di-acetyl adipic ether) with potash, neutralising the residue with H_2SO_4 , extracting with ether, washing the ether with water, drying and evaporating (Perkin, jun, *C J* 57, 229). Colourless oil, v sol ether and alcohol, sl sol water. Its alcoholic solution is coloured violet by $FeCl_3$. On hydrolysis it yields acetyl-valeric acid and acetic acid.

Di-methyl-butylene-diketone dicarboxylic ether $C_8H_{14}O_6$ *ie* $CH_3COCH(CO_2Et)CH_2CH_2CH(CO_2Et)COCH_3$, *Ethylene diaceto acetic ether* *Di acetyl adipic ether*. Formed by the action of sodium (46 g) on aceto acetic ether (260 g) and ethylene bromide (190 g), dissolved in alcohol (Perkin, jun, *C J* 57, 215). It may be purified by conversion into the yellow flocculent di sodium compound ($AcCNa(CO_2Et)CH_2$)₂, decomposing this with very dilute HCl , and extracting with ether. Thick oil, miscible with alcohol and ether, sl sol dilute aqueous KOH . $FeCl_3$ colours its alcoholic solution intense violet red. Combines with great difficulty with $NaHSO_4$. Decomposed by heat into di-methyl butylene diketone carboxylic ether, and the two ethers

converts the dicarboxylic ether into the diimide ($CH_2C(NH)CH(CO_2Et)CH_2$)₂ [174°] which is reconverted by warming with dilute HCl into the original ketonic ether.

Phenyl hydrazide $(CH_2C(N_2HPh)CH(CO_2Et)CH_2)_2$ [α 145°]. Formed by heating di-methyl butylene diketone carboxylic ether with phenyl hydrazine on the water bath (Perkin, jun, a Obremsky, *B* 19, 2049; Perkin, jun, *C J* 57, 221). Plates or needles (from $MeOH$), v sol conc $HClAq$, insol alkalis, v sl sol ether. At 200° it gives off $EtOH$ (2 mols), forming di-oxy di-phenyl dimethyl ethylene-di-pyrazole tetrahydride

METHYL-ISOBUTYL-GLYOXALINE *Methylo iodide* $C_8H_{14}N_2I_2$ *ie* $N_2C_2H_4MeC_2H_4MeI$ [170°]. Formed by treating isobutyl glyoxaline (glyoxal-isocamylne) with MeI in $MeOH$ (Radziszewsky, a Szul, *B* 17, 1294). Trimetric prisms (from alcohol).

METHYL-n-BUTYL KETONE $CH_3COCH_2CH_2CH_2CH_2COCH_3$ (127°) *SG* 2°830. Formed by the oxidation of sec hexyl alcohol (Erlenmeyer, a Wanklyn, *A* 135, 144; Schorlemmer, *A* 161, 263). Combines with $NaHSO_4$. Gives on oxidation acetic, n-butyric, and valeric acids (Wagner, *B* 18, 2267).

Methyl isobutyl ketone $CH_3COCH_2CH_2CH_2CH_2COCH_3$ (115°) *SG* 2°8195, 2°8034 (Wagner, *J R* 16, 703). A product of the distillation of potassium isovalerate with $NaOAc$ (Williamson, *A* 81, 86). Formed by the action on valeryl chloride of $ZnMe$, followed by water. Formed also by boiling isopropyl-aceto acetic ether with baryta water (Frankland, a Duppes, *A* 145, 82).

Combines with $NaHSO_4$. Yields on oxidation acetic, isobutyric, and isovaleric acids.

Methyl sec-butyl ketone $CH_3COCHMeCH_2CH_2CH_3$ (118°) *V* *SG* 14°5 8181. Formed by boiling methyl ethyl acetoacetic ether with dilute KOH or baryta water (Walsleben, *A* 219, 307; Wagner, *J R* 16, 711). Oil, smelling of peppermint. Oxidised by chromic acid mixture to methyl ethyl ketone and $HOAc$. Sodium reduces it to the corresponding hexyl alcohol and methyl sec butyl pinacone [249°].

Methyl tert-butyl ketone $CH_3COCHMe_2$, *Pinacolone* (105°) (Schiff, *B* 19, 562) *SG* 2°8265, 1°800.

Formation—1 By distilling pinacone with dilute sulphuric acid (Fittig, *A* 114, 56).—2 By the action of CMe_2COCl on $ZnMe_2$, followed by water (Butlerow, *A* 174, 125).—3 By the dry distillation of calcium isobutyrate (Barbaglia, a Gucci, *B* 13, 1572).

Properties—Liquid, smelling of peppermint, nearly insol water. Sodium amalgam forms the corresponding hexyl alcohol. Combines with $NaHSO_4$. Chlorine forms pungent $C_8H_{14}ClO$ crystallising in needles [51°], (178°).

Oxim $CH_3C(NOH)CMe_2$, [75°]. Slender needles, very volatile with steam (Janny, *B* 15, 2780). May be sublimed. Sl sol cold, v sol hot, water. Has a camphor like smell and taste. Not decomposed by acids.

Methyl isobutyl diketone $C_8H_{14}O_2$ *ie* $CH_3COCH_2CH_2CH_2CH_2COCH_3$, *Acetyl isovaleryl Diketoheptane* (138°) *SG* 2°908. Formed by distilling its mono oxim with dilute H_2SO_4 (Otte, a Pechmann, *B* 22, 2122). Yellow oil with irritating smell, becoming fruity when diluted. Sl sol water.

Mono oxim $CH_3COCH(NOH)CH_2CH_2CH_2CH_2COCH_3$, *Acetyl isobutyl acetone* [42°]. Formed by adding $NaNO_2$ (10 g) to a solution of isobutyl aceto acetic ether (27 g) in water (300 cc) and KOH (8 g), and extracting with ether (Treadwell, a Westenberger, *B* 15, 2786). White plates, v sol alcohol and ether, sl sol cold water, dissolves in alkalis.

Dioxim $CH_3C(NOH)C(NOH)CH_2CH_2CH_2CH_2COCH_3$ [c 172°]. Small white shining plates (from dilute alcohol) (O a P).

Oxim phenylhydrazide $C_{13}H_{18}N_2O$ *ie* $CH_3C(N_2HPh)C(NOH)CH_2CH_2CH_2CH_2COCH_3$ [151°]. Almost colourless needles.

Phenylhydrazide $C_{13}H_{18}N_2O$ [98°]. Almost colourless needles.

Diphenylhydrazide $C_{19}H_{24}N_4$ *ie* $CH_3C(N_2HPh)C(N_2HPh)CH_2CH_2CH_2CH_2COCH_3$ [116°]. Almost colourless needles.

METHYL n-BUTYL KETONE CARBOXYLIC $CH_3C_2H_4O_2$ *ie*

$CH_3COCH_2CH_2CH_2CH_2CO_2H$ *ω*-Acetyl valeric acid [42°]. A product of the hydrolysis of di-methyl butylene diketone carboxylic ether by a solution of KOH in methyl alcohol (Perkin, jun, *C J* 57, 231). Colourless crystals, v sol water, alcohol, and ether. Its ammonium salt is very soluble— AgA' leafy masses (from hot water). The cupric salt forms minute spherules.

METHYL-ISOBUTYL-KETONE SULFONIC ACID $CH_3COCH_2CH_2CH_2CH_2SO_3H$. The sodium salt of this acid is slowly formed by the action of a

saturated solution of NaHSO_4 on mesityl oxide. It is easily soluble in water and alcohol, melts at 95° , is not attacked by Na_2CO_3 , but by NaOH it gives mesityl oxide (Pinner, *B* 15, 592).

METHYL BUTYL KETOXIM *v.* Oxim of METHYL BUTYL KETONE

METHYL *n* BUTYL OXIDE $\text{C}_6\text{H}_{12}\text{O}$ *ie* $\text{CH}_3\text{O C}_4\text{H}_9$ (70.3°) SG 7635 SV 127.2 CE (0° - 10°) 00125 (Dobrenner, *A* 243, 3).

Methyl isobutyl oxide $\text{CH}_3\text{O C}_4\text{H}_9$ (60°). One of the products of the action of NaOCH_2Pr on methylene iodide or iodoform (Gorboff, *J pr* [2] 41, 238, 254). Oil. Conc HIAq yields MeI and isobutyl iodide.

METHYL-ISOBUTYL-PHENOL $\text{C}_{11}\text{H}_{14}\text{O}$ *ie* $\text{C}_6\text{H}_5(\text{CH}_2)(\text{C}_2\text{H}_5)\text{OH}$ [136] (236°). *Isobutyl o cresol*. Formed by the action of nitrous acid on methyl isobutyl phenyl amine (Effront, *B* 17, 2324). Oil. V sol alcohol and ether, nearly insol water.

Isomeride *v.* Methyl ether of ISOBUTYL-PHENOL

METHYL-ISOBUTYL PHENYL AMINE

$\text{C}_6\text{H}_5(\text{CH}_2)(\text{C}_2\text{H}_5)\text{NH}_2$ [136] *Isobutyl tolyl amine or toluisobutylamine* (243°). Formed by heating *o* toluidine hydrochloride with isobutyl alcohol at 200° - 300° (Effront, *B* 17, 2317). Colourless liquid. Volatile with steam. Miscible with alcohol and ether, nearly insol water.

Salts— B^+HCl . Long thin needles, sl sol cold water, v sol hot water— B^+HBr long soluble needles— $\text{B}^+\text{H}_2\text{SO}_4$ needles, sl sol cold water— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ silvery needles, insol ether.

Formyl derivative $\text{C}_{11}\text{H}_{15}\text{NH(COH)}$ [106°]. Colourless tables, v sol alcohol and ether, nearly insol cold water.

Acetyl derivative $\text{C}_{11}\text{H}_{15}\text{NHAc}$ [162°]. Colourless plates, sparingly sol hot water, easily in alcohol.

Benzoyl derivative $\text{C}_{11}\text{H}_{15}\text{NHBz}$ [168°]. Small white needles, insol cold water, v sl sol hot.

METHYL-ISOBUTYL PHENYL-AMINE

$\text{C}_6\text{H}_5(\text{CH}_2)(\text{C}_2\text{H}_5)\text{NH}$ [156] (244°). Formed by heating *o* toluidine with isobutyl alcohol and ZnCl_2 at 270° - 280° (Effront, *B* 17, 2339). Colourless liquid. Volatile with steam.

Salts— B^+HCl . Plates— $\text{B}^+\text{H}_2\text{SO}_4$ plates— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ easily sol ether.

Formyl derivative $\text{C}_{11}\text{H}_{15}\text{NH(CHO)}$ [105°]. White plates, v sol alcohol and ether, nearly insol water.

Acetyl derivative $\text{C}_{11}\text{H}_{15}\text{NHAc}$ [141°]. Long silky needles.

Benzoyl derivative $\text{C}_{11}\text{H}_{15}\text{NHBz}$ [142°]. Silvery plates.

METHYL - ISOBUTYL - PHENYL - DI -

METHYL-AMINE $\text{C}_6\text{H}_5(\text{CH}_2)(\text{C}_2\text{H}_5)\text{NMe}$ [136] *Dimethyl toluisobutylamine* (250°). Colourless liquid. Formed by methylation of methyl isobutyl phenyl amine— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_4$ (Effront, *B* 17, 2339).

DI METHYL-DI-BUTYL-DI PHENYL-THIO-UREA *v.* DI BUTYL DI-TOLYL THIOUREA

METHYL BUTYL PINACONE *v.* DI-OXY-DODECANE

DI METHYL DI ISOBUTYL-PYRAZINE

$\text{C}_{11}\text{H}_{20}\text{N}_2$ *ie* $\text{N} \langle \text{CMe C(C}_2\text{H}_5) \rangle \text{N}$ *Di isobutyl-ketone* (243°). Formed by reducing the oxim of methyl isobutyl diketone $\text{Me CO C(NO}_2\text{H) C}_2\text{H}_5$

with tin and HCl (Lang, *B* 18, 1364, Oeconomidis, *B* 19, 2526, Wolff, *B* 20, 433). Yellow oil— $\text{B}^+\text{H}_2\text{PtCl}_4$, orange needles.

DI METHYL ISOBUTYL PYRIDINE $\text{C}_{11}\text{H}_{17}\text{N}$ *ie* $\text{N} \langle \text{CMe CH} \rangle \text{C}_2\text{H}_5$, *Isobutyl lutidine*,

(210° - 213°) SG 8961. Formed by distilling its carboxylic acid with lime (Engelmann, *A* 231, 65). Oil, smelling of violets. Tastes bitter. More soluble in cold water than in hot water— $\text{B}^+\text{H}_2\text{PtCl}_4$, [209°]. Yellow crystalline pp— $\text{B}^+\text{H}_2\text{CrO}_4$, Yellow plates, v sol boiling water—Picrate [115°]. Yellow needles.

Hexahydrate $\text{C}_{11}\text{H}_{21}\text{N}$ *ie*

$\text{NH} \langle \text{CHMe CH} \rangle \text{CH C}_2\text{H}_5$, *s Isobutyl lupetidine*. *Di methyl isobutyl piperidine* (198°) at 720 mm. Formed by reducing di methyl isobutyl pyridine in alcoholic solution with sodium (Jaekle, *A* 246, 47). Oil. With NaNO_2 and HCl it yields a nitroso compound— B^+HCl [184°]. Prisms, v sol water and alcohol— B^+HBr . Prisms. The platinochloride and chromate could not be crystallised.

DI METHYL-ISOBUTYL PYRIDINE DI-CARBOXYLIC ACID $\text{C}_{11}\text{H}_{17}\text{NO}_4$ *ie*

$\text{N} \langle \text{CMe C(CO}_2\text{H)} \rangle \text{C}_2\text{H}_5$, [273°]. Formed by boiling its diethyl ether with alcoholic, and afterwards with aqueous, potash (Engelmann, *A* 231, 57). Long monoclinic prisms (containing 2aq). Decomposed by fusion. M sol cold, v sol hot, alcohol— CaA'' 3aq. Small four-sided pyramids, v sol water— BaA'' 5aq— $\text{H}_2\text{A}''\text{HCl}$. M sol cold water.

Mono ethyl ether HEtA'' [185°]. Formed by boiling the di ethyl ether with alcoholic potash. Long prisms, v sol water and alcohol— $\text{Ba(EtA}'')$ 3aq— $\text{HEtA}''\text{HCl}$ 2aq thick prisms.

Di ethyl ether $\text{Et}_2\text{A}''$ (312° - 318°). Formed by passing nitrous acid gas into an alcoholic solution of its dihydride. Thick oil— $\text{Et}_2\text{A}''\text{HCl}$ long needles, decomposed by water into HCl and $\text{Et}_2\text{A}''$ — $(\text{Et}_2\text{A}'')_2\text{H}_2\text{PtCl}_4$, [208°]. Cubes.

Dihydrate of the diethyl ether

$\text{NH} \langle \text{CMe C(CO}_2\text{H)} \rangle \text{CH C}_2\text{H}_5$, [100°]. Formed by warming acetoacetic ether with isovaleric aldehyde ammonia in alcohol (E). Long prisms, v sol alcohol, ether, and benzene.

METHYL ISOBUTYL SULPHATE $\text{C}_6\text{H}_5(\text{CH}_2)(\text{C}_2\text{H}_5)\text{SO}_3$ *ie* $(\text{CH}_2)(\text{C}_2\text{H}_5)\text{SO}_3$, appears to be formed by the action of methyl alcohol on $\text{C}_6\text{H}_5\text{O SO}_2\text{Cl}$, the product of the action of isobutyl alcohol on SO_2Cl (Behrend, *J pr* [2] 15, 34). Decomposed by water into HOMe and $\text{C}_6\text{H}_5\text{O SO}_2\text{OH}$.

DI METHYL ISOBUTYRYL-ACETIC ETHER *v.* DI ISOPROPYL KETONE CARBOXYLIC ETHER

METHYL CAFFEIC ACID *v.* CAFFEIC ACID

METHYL CAFFURIC ACID *v.* CAFFEINE

METHYL CARBAMATE $\text{NH}_2\text{CO}_2\text{Me}$

Methyl urethane [52°] (G), [56°] (F & K) (177°). Formed from NH_2COCl and excess of methyl alcohol (Gattermann, *A* 244, 39). Formed also from $\text{C}_6\text{H}_5(\text{N(NO}_2)_2\text{CO}_2\text{Me})$, by the action of NH_3 (Franchimont & Klobbe, *R T C* 7, 343).

METHYL CARBAMIC ACID

NHMeCO_2H . The methylammonium salt $\text{NHMeCO}_2\text{NH}_2\text{Me}$ appears to be formed by pass-

ing CO₂ into dry methylamine (Wurtz, *A Ch* [3] 80, 450, 461)

Methyl ether NHMe CO₂Me (158°) SG 15 1065 Formed by treating methyl chloroformate Cl CO₂Me with an aqueous solution of methylamine (Franchimont a Klobbie, *R T C* 7, 358) Colourless liquid, with characteristic odour With pure HNO₃ it yields a characteristic nitro-derivative

Ethyl ether NHMe CO₂Et (170°) Formed from methylamine and chloroformic ether (Schreiner, *J pr* [2] 21, 124) Oil, with pleasant odour When boiled with potash or baryta it yields alcohol, methylamine, and K₂CO₃

Chloride NHMe COCl (90°) (94°) From COCl₂ and methylamine hydrochloride (Gattermann a Schmidt, *B* 20, 118) Decomposed on boiling

Di methyl-carbamic acid *NMe₂ CO₂H

Methyl ether NMe₂ CO₂Me (131°) SG 15 1012 Formed by treating Cl CO₂OMe with an aqueous (33 p c) solution of dimethylamine (Franchimont a Klobbie, *R T C* 8, 299) Colourless liquid, smelling like menthol Pure HNO₃ forms NMe₂(NO₂) CO₂Me

Ethyl ether NMe₂ CO₂Et (140°) (Schreiner, *J pr* [2] 21, 125), (147°) (Franchimont a Klobbie, *R T C* 3, 223) SG 15 978 From Cl CO₂Et and dimethylamine With ammonia it does not form NMe₂ CO₂NH₂

Chloride NMe₂ COCl (165°) From dimethylamine and a solution of COCl₂ in benzene (Michler a Escherich, *B* 12, 1162) Liquid, with peculiar odour, v sol ether and CS₂ Decomposed slowly by water into HCl, dimethylamine, and CO₂

METHYL CARBAMINE C₂H₇N 1 e CH₃ N O

Methyl isocyanide *Methyl cyanide* *Methyl carbonylamine* *Isocetonitrile* Mol w 41 [-45°] (59.6°) VD 144 (calc 142) SG 4 756 S 10 at 15° Formed by the action of MeI (1 mol) on silver cyanide (2 mols) the product being decomposed by KOH and dried over CaCl₂ (Gautier, *C R* 63, 924, 65, 468, 862, 66, 1214, A 152, 222, *A Ch* [4] 17, 203) Formed also by the action of MeI on mercuric fulminate (Calmels, *J pr* [2] 80, 319, *C R* 99, 794)

Properties—Liquid with powerful odour, producing nausea

Reactions—1 *Aqueous acids* decompose it into methylamine and formic acid—2 HOAc forms CH₃NH CHO and Ac₂O—3 Oxidised by HgO at 50° to methyl cyanate CH₃N CO and a compound Me₂N₂C₂O₄(NH₂CHO) [175°] HgO in ethereal solution appears also to form diformamide NH(CHO)₂ or, rather, a compound Me₂N₂C₂O₄(NH(CHO))₂ [163°] (Gautier, *C R* 67, 804)—4 With AgCy it forms a compound MeNCAGCy (80°–90°) (Meyer, *J* 1856, 523) Salt—(MeNC)₂3HCl. Formed by passing HCl into an ethereal solution of methyl carbamine Crystalline Decomposed by water, partially reproducing methyl carbamine—5 MeI acts in a complicated manner (Lubavine, *Bl* [2] 45, 246, Gautier, *A Ch* [4] 17, 148)

Tri-methyl-carbamine. A name used by Rudnief (*Bl* [2] 83, 297) to denote *tert*-BUTYLAMINE

METHYL-SEMI-CARBAZIDE C₂H₇N₂O 1 e NH₂CO NH NHMe [118°]. Formed from

methyl-hydrazine acid sulphate KHO and KONO (Brüning, A 253, 10) Prismatic tables, v sol water and EtOH, m sol ether

METHYL-CARBAZOLE C₈H₁₁N 1 e

C₈H₁₁ > NMe [87°] Formed by heating potassium carbazole with MeI at 180° (Graebe, A 202, 23) Micaceous leaflets or needles, insol water, sol ether Conc H₂SO₄ containing a little HNO₃ gives a green colour—Picrate C₁₅H₁₁NC₂H₃(NO₂)₂OH [141°] Dark red needles

METHYL CARBIMIDO ALLYL THIO UREA

SC < NH > C NMe or C₂H₅ NH CS N C NMe

Allyl-thio-carbamine-methyl cyanide [110°] Formed by the action of methyl iodide upon sodium carbimido allyl thio urea Crystalline V sol water and alcohol Indifferent body (Wunderlich, B 19, 448)

METHYL-CARBIMIDO-ETHYL-THIO-UREA

SC < NH > C NMe or EtNH CS N C NMe

Ethyl-thio-carbamine-methyl cyanide [162°]

Formed by the action of methyl iodide upon sodium carbimido ethyl-thio-urea (Wunderlich, B 19, 448)

TRI-METHYL CARBINOL v *Tert* BUTYL

ALCOHOL

METHYL CARBONATES

Hydrogen methyl carbonate *MeHCO₂ The Ba salt, Ba(MeCO₂)₂, appears to be the white pp formed when CO₂ is passed into a solution of BaO in anhydrous methyl alcohol (Dumas a Pélignot, A Ch [2] 74, 6) It is insol alcohol, but dissolves in water, the solution soon depositing BaCO₃

Di-methyl carbonate C₂H₆O₂ 1 e (CH₃)₂CO₂ [0.5°] (Röse, A 205, 231) (91°) SG 2 1069 HF p 138,390 HF v 136,360 (Thomsen, Th) Formed by boiling methyl chloroformate ClCO₂Me with lead oxide (Counciler, B 13, 1697) Formed also from ClCO₂Me and NaOMe (Schreiner, J pr [2] 22, 354) Oil, insol water, sol alcohol and ether Converted by dry chlorine into hexa-chloro di methyl carbonate (q v)

METHYL-CARBOPYRIDIC ACID v METHYL-

PYRIDINE CARBOXYLIC ACID

METHYL-CARBOSTYRIL v *Methyl ether* of

CARBOSTYRIL and Oxy METHYL QUINOLINE

METHYL CETYL KETONE C₁₈H₃₈O 1 e

C₁₈H₃₈ CO OH₂ [52°] (252° at 100 mm) Formed by distilling a mixture of barium margarate and barium acetate (Krafft, B 15, 1707). Yields palmitic and acetic acids on oxidation

METHYL-CHELIDAMIC ACID v CHELIDONIC

ACID

METHYL-CHLORACETOL v. DI CHLORO-

PROPANE

METHYL CHLORIDE CH₃Cl *Chloro-*

methane Mol w 50.5 (-23.7°) (Regnault) VD 173 (calc 175) SG 2 9915, 2 9523 (Vincent a Delaachanal, A Ch [5] 16, 429) S 5.03 at 7°, 8.46 at 20° (Baeyer, A 107, 181) S. (alcohol) 35 S (HOAc) 40 HF p 22,550 HF v 21,970 (Thomsen) SV 50.8 (Lowsen, A 254, 68) Latent heat of evaporation 96,900 at 0° (Chappuis, A Ch [6] 15, 507)

Formation—1 By heating a mixture of NaCl (2 pts), wood spirit (1 pt) and H₂SO₄ (8 pts) and collecting the gas over water

(Dumas & Péligot, *A Ch* 61, 193, *A* 15, 17) — 2 By exposing a mixture of equal volumes of methane and chlorine to daylight (Berthelot, *A Ch* [3] 52, 97)

Preparation — 1 HCl is passed into MeOH (2 pts) containing ZnCl₂ (1 pt) The gas is passed through KOH and H₂SO₄ (Groves, *C J* 27, 641, *A* 174, 378) — 2 By heating trimethylamine hydrochloride at 260°, the reaction being perhaps 3NMe₃·HCl = 2NMe₃ + NH₃ + 3MeCl (Vincent, *J Ph* [4] 30, 132)

Properties — Colourless gas, with ethereal odour Burns with a bright flame, edged with green

Reactions — 1 When passed through a red-hot tube it deposits charcoal and yields HCl, methane, ethylene, CO, and naphthalene (Perrot, *A* 101, 375) — 2 When passed over heated potash-lime it yields potassium formate, KCl, and hydrogen — 3 Not attacked by chlorine in diffused daylight, but when the mixture is exposed to direct sunlight, substitution occurs, the products being methylene chloride, chloroform, and CCl₄ The chlorination may also be effected by passing a mixture of chlorine and methylchloride over animal charcoal at 250°–350° (Damoiseau, *C R* 92, 42) — 4 When equal volumes of methyl chloride and of an amine are submitted to a pressure of 25 atmospheres for 48 hours the following reactions occur — (a) Ammonia forms NMe₃·HCl, NMe₃·HCl, and 2NH₃·Cl — (b) Methylamine forms 2NMe₃·Cl and NMe₃·Cl — (c) Dimethylamine reacts with formation of NMe₃·HCl and NMe₃·Cl — (d) Trimethylamine forms NMe₃·Cl (Vincent & Chappuis, *Bl* [2] 45, 496)

Hydrate MeCl 9aq Formed by cooling below 0° water into which MeCl is passed Its vapour-tension has been studied by De Forcrand & Vilard *C R* 106, 1357, 1404)

METHYL-CHLORO-ALLYL CARBINOL *v* CHLORO PENTYL ALCOHOL

DI-METHYL-CHLORO-ANILINE *v* CHLORO DI METHYL ANILINE

TRI-METHYL CHLORO-AURO-PHOSPHITE Me₃PAuClO₂ [101°] Formed by the action of pure methyl alcohol on aurous chloride and phosphorus (Lindet, *C R* 103, 1014) Slender colourless needles, insol water, sol MeOH

METHYL CHLORO-BUTYL CARBINOL *v* CHLORO HEXYL ALCOHOL

METHYL - CHLORO - CARBOSTYRIL *v* CHLORO OXY METHYL QUINOLINE

METHYL CHLORO-ETHYL OXIDE C₂H₅ClO *v* CH₃·CHCl·OMe (72°–75°) SG 12 996 Formed from aldehyde (1 vol), methyl alcohol (1½ vols), and dry HCl at 0° (Geuther, *A* 225, 270)

METHYL TETRA-CHLORO-ETHYL OXIDE C₂H₂Cl₄O *v* CCl₃·CHCl·OCH₃ (178°) SG 2 184 Formed by the action of PCl₅ on chloral methylate (Magnanini, *G* 16, 330) Colourless liquid

METHYL CHLORO-FORMAMIDE *v* CHLORO FORMIC ACID

METHYL CHLORO - PROPYL KETONE C₃H₇ClO *v* CH₃·CO·CHClEt (180°) Formed by heating CH₃·CO·CClEt·CO₂Et with dilute HCl at 180° (Conrad, *A* 186, 241)

Methyl tri-chloro-propyl ketone C₃H₂Cl₃O *v* CH₃·CO·C₂H₂Cl₂ (193°) Formed by oxidising

C₂H₅Cl, CHMe OH with chromic acid mixture (Garzaroli Thurnlackh, *A* 223, 152) Heavy oil Does not combine with NaHSO₄ Yields CO₂, acetic acid, and HCl on oxidation

DI METHYL-CHLORO - QUINALDINE *v*

CHLORO TRI METHYL QUINOLINE

METHYL-TRI CHLORO-QUINOLINE *v* TRI-CHLORO METHYL-QUINOLINE

METHYL DI - CHLORO - VINYL OXIDE C₂H₂Cl₂O *v* CCl·CH·OCH₃ (110°) SG 2 12934, 122 11574 Prepared by heating tri-chloro ethylene with KOMe, being ppt on addition of water (Denaro, *G* 14, 117) Colourless oil, with an odour resembling that of acetal Decomposed on exposure to air, with evolution of HCl When heated with dilute H₂SO₄ it yields di chloro acetic orthoaldehyde

Methyl tri chloro-vinyl oxide CCl₂·CCl·OCH₃ Readily absorbs dry oxygen, forming the compound CCl₂·CCl·O(OMe), which, by the action of water, gives oxalic acid (Henry, *B* 12, 1838)

METHYL CHRYSOIDINE *v* Benzene-Azo methyl phenylene diamine

METHYL CINNOLINE CARBOXYLIC ACID

C₁₀H₇N₂O₂ *v* C₆H₅·(CO·H) $\begin{matrix} \text{CMe CH} \\ \diagdown \\ \text{N}=\text{N} \end{matrix}$ [c 230°]

Small tables or fine needles Sol acetic acid, sl sol hot alcohol and hot water, insol cold water Dissolves both in aqueous acids and alkalis, forming easily soluble salts Obtained, as a yellow pp, by adding NaNO₂ to a cold solution of the hydrochloride of amido propenyl benzoic acid C₆H₄·(CMe CH)·(NH₂)·CO₂H [2 4], very probably di azo-propenyl-benzoic acid C₆H₄·(CO₂H) $\begin{matrix} \text{CMe CH} \\ \diagdown \\ \text{N}=\text{N OH} \end{matrix}$ is first formed, which then splits off H₂O (Widman, *B* 17, 722)

METHYL-CITRACONIC ACID C₇H₈O₄ [100°]

A product of the dry distillation of methyl-paraconic acid (Frankel *A* 255, 25) Long needles (from CHCl₃) Reduced by sodium amalgam to ethyl succinic acid — CaA''aq — BaA''4aq — Ag A'

METHYL COCAINE C₁₇H₂₁NO₄ [47°] Extracted from synthetic cocaine (cf vol 1 p 230), in which it occurs in very small quantity (Liebermann & Giesel, *B* 23, 508, 926) An oil, which crystallises after standing some hours Ppd by Na₂CO₃ from its salts Very sol ether, chloroform, benzene, and ligroin It can be separated from ordinary cocaine by means of its nitrate A 5 4 pc solution of the hydrochloride in a 2 dm tube gave a rotation of +4 5° By heating with water it is not so easily decomposed as ordinary cocaine By boiling with hydriodic acid MeI is split off By hydrochloric acid it is split

up finally into methyl alcohol, benzoic acid, and methyl ecgonine hydrochloride. This reaction is also more difficultly brought about than with ordinary cocaine. Methyl cocaine appears to be identical with 'dextro cocaine,' a body got by heating the methyl ether of dextro ecgonine with BzCl (Einhorn & Marquardt, *B* 23, 468).

Salts— B^+HCl [210°] needles or columns forming rosettes (from hot alcohol), much less soluble than the hydrochloride of ordinary cocaine—Sulphate plates, v sol water, sl sol alcohol—Nitrate crystals, sl sol water—Platino-chloride $(\text{C}_{15}\text{H}_{23}\text{NO}_2\text{HCl})_2\text{PtCl}_6$ glittering yellowish needles (from hot water)—Auro-chloride $\text{C}_{15}\text{H}_{23}\text{NO}_2\text{HClAuCl}_4$ [148°] needles, melts under water to a yellow oil.

METHYL CODEINE $\text{C}_{15}\text{H}_{21}\text{NO}_2$, $\pm e$
 $\text{C}_{15}\text{H}_{21}\text{MeNO}$, or $\text{C}_{15}\text{H}_{21}\text{Me}_2\text{NO}_2$ [118.5°]
 $[\alpha]_D^{20} = -209^\circ$ in a 4 c solution (in 97 p c alcohol) at 15°. Formed by boiling codeine methyl iodide $\text{C}_{15}\text{H}_{21}\text{NO}_2\text{MeI}$ with potash, and extracting with benzene (Grimaux, *A Ch* [5] 27, 276, Hesse, *A* 222, 218). Anhydrous prisms (from alcohol or ether), or hydrated crystals (containing aq) (from water). Insol water, v e sol hot alcohol, m sol ether. Its solution in conc H_2SO_4 is violet, but becomes blue on heating. Boiling Ac_2O forms a compound $\text{C}_{15}\text{H}_{21}\text{O}_3$ [131°]. Its hydrochloride forms a brown solution in H_2SO_4 , which becomes violet on warming, and finally blue on exposure to the air— B^+HCl 2aq needles S 9 at 18°. V e sol alcohol, sl sol NaCl aq— $\text{B}^+\text{H}_2\text{PtCl}_6$ aq.

Acetyl derivative $\text{C}_{17}\text{H}_{23}\text{AcMe}_2\text{NO}_2$ [66°] Formed by heating methyl codeine with Ac_2O at 85°, adding aqueous NH_3 , and extracting with ether (Hesse, *A* 222, 222). Glittering tables (from ether), v sol alcohol and ether, sl sol water, insol KOH aq. Alcoholic potash forms potassium acetate and methyl codeine— $(\text{C}_{17}\text{H}_{23}\text{AcMe}_2\text{NO}_2)\text{HCl}$ 2aq satiny plates, sl sol cold water— $(\text{C}_{17}\text{H}_{23}\text{AcMe}_2\text{NO}_2)_2\text{H}_2\text{PtCl}_6$ 4aq yellow laminae— $(\text{C}_{17}\text{H}_{23}\text{AcMe}_2\text{NO}_2)\text{HNO}_3$ 3aq satiny plates— $(\text{C}_{17}\text{H}_{23}\text{AcMe}_2\text{NO}_2)_2\text{H}_2\text{SO}_4$ 8aq.

(a) **Methyl iodide** $\text{C}_{15}\text{H}_{21}\text{NO}_2\text{MeI}$ 3aq prisms, formed at once on dissolving methyl codeine in a mixture of MeI and methyl alcohol (Hesse).

(b) **Methyl iodide** $\text{C}_{15}\text{H}_{23}\text{NO}_2\text{MeI}$ Slender crystals, formed by boiling the preceding with aqueous NaOH , and ppg with KI . It is less soluble in water than its (a) isomeride. Ag_2SO_4 forms $(\text{C}_{15}\text{H}_{23}\text{NO}_2\text{Me})_2\text{SO}_4$, crystallising in plates.

(a) **Methyl chloride** $\text{C}_{15}\text{H}_{23}\text{NO}_2\text{MeCl}$ From the (a)-iodide and AgCl . Amorphous. With platonic chloride it yields a yellow flocculent pp of $(\text{C}_{15}\text{H}_{23}\text{NO}_2\text{MeCl})_2\text{PtCl}_6$ 8aq. With Ac_2O it yields $\text{C}_{15}\text{H}_{23}\text{AcNO}_2\text{MeCl}$ 2aq, which crystallises in long satiny needles, v e sol alcohol, sl sol cold water. Its platinochloride $(\text{C}_{15}\text{H}_{23}\text{AcNO}_2\text{MeCl})_2\text{PtCl}_6$ 4aq is a yellow crystalline pp.

(b) **Methyl chloride** $\text{C}_{15}\text{H}_{23}\text{NO}_2\text{MeCl}$ 3aq Radiating crystalline mass, v sol water and alcohol. With conc H_2SO_4 it gives a purple colour. With platonic chloride it yields an orange pp of small needles of the platinochloride $(\text{C}_{15}\text{H}_{23}\text{NO}_2\text{MeCl})_2\text{PtCl}_6$ aq. With Ac_2O it yields amorphous $\text{C}_{15}\text{H}_{23}\text{AcNO}_2\text{MeCl}$, which forms $(\text{C}_{15}\text{H}_{23}\text{AcNO}_2\text{MeCl})_2\text{PtCl}_6$ 8aq, a yellow powder.

Methyl hydroxide $\text{C}_{15}\text{H}_{23}\text{NO}_2\text{MeOH}$. Formed from the (b) methyl sulphate and baryta. Colourless plates, insol ether, v sol alcohol. Strongly alkaline in reaction. Conc H_2SO_4 forms a blue solution. Gives off tri-methylamine when strongly heated.

METHYL COLCHICINE $\text{C}_{25}\text{H}_{35}\text{NO}_5$, $\pm e$
 $\text{C}_{15}\text{H}_2(\text{OMe})_2(\text{NAcMe})\text{CO}_2\text{Me}$. Occurs in the mother liquor from which the compound of colchicine with chloroform has separated (vol u p 234). Decomposed by boiling dilute HCl into methyl chloride and methyl colchicine $\text{C}_{15}\text{H}_2(\text{OMe})_2(\text{NAcMe})\text{CO}_2\text{H}$ (Johanny & Zeisel, *M* 9, 871).

DI METHYL-COLCHICINIC ACID v *D*.
 methyl derivative of COLCHICINIC ACID.

Tri methyl-colchicinic acid $\text{C}_{15}\text{H}_2\text{NO}_5$, $\pm e$
 $\text{C}_{15}\text{H}_2(\text{OMe})_3(\text{NH}_2)\text{CO}_2\text{H}$ [150°] Formed by the action of HCl on colchicine (*q* v). Forms a platinochloride $\text{B}^+\text{H}_2\text{PtCl}_6$ 2aq. On warming with acetic anhydride it yields colchicine $\text{C}_{15}\text{H}_2(\text{OMe})_2(\text{NHAc})\text{CO}_2\text{H}$. With MeOH it forms an addition product $\text{C}_{15}\text{H}_2\text{NO}_5\text{MeOH}$. On warming with MeOH , methyl iodide, and sodium it yields 'tri methyl colchidimethinic acid' $\text{C}_{15}\text{H}_2(\text{OMe})_3(\text{NMe}_2)\text{CO}_2\text{H}$ [125°]. The methyl ether of this body forms an iodomethylate $\text{C}_{25}\text{H}_{35}\text{NO}_5\text{Iaq}$ (Johanny & Zeisel, *M* 9, 877).

METHYL-CONINE v CONINE.

METHYL-COUMARIC ACID v *Methyl derivative of COUMARIC ACID*.

Di-methyl di coumaric acid so called v *Di METHYL DI-COUMARIN*.

METHYL COUMARILIC ACID $\text{C}_{10}\text{H}_8\text{O}_3$, $\pm e$
 $\text{C}_6\text{H}_5\text{C}(\text{OMe})_2\text{CO}_2\text{H}$ [126°] Formed by the action of dilute KOH upon the methyl derivative of *exo* bromo coumaric acid (Perkin, *C J* 39, 423). Needles (from CS_2).

(b) **Methyl coumarilic acid** $\text{C}_{10}\text{H}_8\text{O}_3$, $\pm e$
 $\text{C}_6\text{H}_5\text{C}(\text{OMe})_2\text{CO}_2\text{H}$ [189°] Formed by saponifying its ethyl ether with alcoholic potash (Hantzsch, *B* 19, 1290). Feathery needles (from dilute alcohol). Decomposed by heat into CO_2 and (b) methyl coumarone— KA aq needles— NH_4A aq needles (from water)— BaA , 3aq— AgA minute prisms.

Ethylether EtA [51°] (290°) Formed by the action of sodium phenylate NaOC_6H_5 upon chloro aceto acetic ether, the resulting phenoxy aceto acetic ether being condensed by cold conc H_2SO_4 (Hantzsch).

Amide $\text{C}_6\text{H}_5(\text{CH}_2)_2\text{O CO NH}_2$; [145°], needles (Hantzsch, *B* 19, 2401).

Di-methyl-coumarilic acid $\text{C}_{11}\text{H}_{10}\text{O}_3$, $\pm e$

$\text{C}_6\text{H}_5(\text{CH}_2)_2\text{C}(\text{CH}_3)\text{CO}_2\text{H}$ *Di methyl coumarone-a carboxylic acid* [225°]

Formation—1 By the action of hot alcoholic KOH upon bromo di methyl cumarin

$\text{C}_6\text{H}_5(\text{CH}_2)_2\text{C}(\text{CH}_3)\text{CBr}$
 $\text{O} \quad \text{O} \quad \text{CO}$
 —2 By saponification

of the ethyl ether obtained by the reaction of sodium *p* cresol and chloro aceto acetic ether.

Properties—Short prisms or tables. On heating the sodium salt with lime di methyl coumarone is obtained.

Ethyl ether AEt [55°], (300° at 728 mm) (Hantzsch & Lang, *B* 19, 1299).

METHYL DECYL KETONE $C_{12}H_{22}O$ \pm CH_3 CO $C_{10}H_{21}$ [21°] (247°) Formed by distilling a mixture of barium acetate and barium hendecate (undecylate) (Krafft, *B* 15, 1708) Yields acetic and decic acids on oxidation

METHYL-DESOXYBENZOLIN *v* *TOLYL BENZYL KETONE*

Dimethyl-desoxybenzol *v* *BENZYL XYLIL KETONE*

METHYL DODECYL KETONE $C_{14}H_{28}O$ \pm CH_3 CO $C_{12}H_{25}$ [34°] (206° at 100 mm) Formed by distilling barium tridecoteate ($C_{13}H_{26}O_2$) Ba with barium acetate (Krafft, *B* 15, 1708) Yields lauric and acetic acids on oxidation

METHYL c-DURYL KETONE $C_{12}H_{18}O$ \pm CH_3 CO C_6H_5 Me [1 2 3 4 5] (259°) From c-durene, AcCl, and $AlCl_3$ (Claus & Fohlisch, *J pr* [2] 38, 230) Oil

Phenyl hydrazide [129°] Lamine

Isomerides *v* *DURYL METHYL KETONES*

METHYL-EGGONINE $C_{15}H_{17}NO$ [264°] A product of the action of HCl on methyl cocaine, the resulting methyl eggonine hydrochloride being decomposed by Ag_2O (Liebermann & Giesel, *B* 23, 510) May be crystallised from methyl alcohol containing a trace of water. Extremely sol water, insol absolute alcohol, v sl sol absolute MeOH. Decomposed by fusion. A 96 p c solution of the hydrochloride exhibits $\alpha = +2^\circ$ —B'HCl [236°], needles (from methyl alcohol ether) —B'HAuCl₄ [220°], lemon yellow needles

Benzoyl derivative Hydrochloride $C_{17}H_{19}NO_2$ HCl The first product of the action of hydrochloric acid on methyl cocaine [47°], the base being just dissolved in HCl and then heated $\frac{1}{2}$ hour at 90° Glassy columns (from hot water) The base is not ppt by carbonate of soda —Aurochloride $C_{17}H_{19}NO$ HCl AuCl₄ The nitrate is v sl sol water

METHYLENE The radicle CH_2 , which is not known to exist in the free state

Dimethylene C_2H_4 , \pm CH_2 CH_2 is called **ETHYLENE** (*q v*)

Trimethylene C_3H_6 , \pm CH_2 $\begin{matrix} \diagup CH_2 \\ | \\ CH_2 \end{matrix}$ H F p

—8470 H.F.v. —4630 This gas is formed

when trimethylene bromide CH_2Br C_2H_4 CH_2Br (140 g) is boiled with sodium (5 g) The contents of the flask become pasty, but still contain much of the bromide (120 g), which can be mostly recovered by filtration (Freund, *J pr* [2] 26, 367) It is also formed by heating tri-methylene bromide with zinc dust and 75 p c alcohol (Gustavson, *J pr* [2] 36, 300) Trimethylene burns with a bright flame and smells like butylene

Reactions —1 Trimethylene is readily absorbed by fuming HI The product is *n* propyl iodide, whereas propylene gives *iso* propyl iodide.

2 Trimethylene is very slowly absorbed by bromine, the product is trimethylene bromide (165°) Propylene is readily absorbed, forming propylene bromide —3 Conc H_2SO_4 forms liquid hydrocarbons, and on diluting and distilling *n* propyl alcohol is got (G) —4 $KMnO_4$ does not oxidise it (Wagner, *B* 21, 1230)

References —TRIMETHYLENE CARBOXYLIC ACIDS, TRIMETHYLENYL METHYL KETONE, and PHENYL TRIMETHYLENYL KETONE

Tri-methylene is a term also applied to the divalent radicle CH_2 CH_2 CH_2

Tetra-methylene is a term applied to the ring CH_2 CH_2

$\begin{matrix} | \\ CH_2 \\ | \end{matrix}$, and it is also used to denote the group CH_2 CH_2 CH_2 CH_2 CH_2 CH_2

Pentamethylene is a name used to denote CH_2 CH_2 $\begin{matrix} \diagup CH_2 \\ | \\ CH_2 \end{matrix}$ $\begin{matrix} \diagup CH_2 \\ | \\ CH_2 \end{matrix}$ CH_2 , and also CH_2 CH_2 CH_2 CH_2 CH_2 CH_2

Hexamethylene is benzene hexahydride According to Baeyer (*A* 258, 156), it should be regarded as lying entirely in one plane

METHYLENE ACETATE *v* *Acetyl derivative of FORMIC ORTHALDEHYDE*, vol 11 p 570

TRIMETHYLENE ACETO ACETIC ACID, so called, *v* vol 1 p 24

METHYLENE DIAMINE *Di benzoyl derivative* $CH(NHBz)_2$ [221°] S (alcohol) 47 at 14.5°, 63 at 22°, *Apparaffin*

Formation —From hippuric acid, PbO_2 and HNO_3 or H_2SO_4 (H Schwarz, *A* 75, 201, *Sit. W* 77, 11 762, J Maier, *A* 127, 162, Kautz *A* Y Schwarz, *A* 223, 40)

Preparation —From benzonitrile (15 g), methylal (6 g) and conc H_2SO_4 (100 g) (Hepp & Spiess, *B* 9, 1424)

Properties —Long white felted needles (from alcohol), v sol CS_2 , ether, and chloroform

Reactions —1 Dissolves unchanged in conc H_2SO_4 , and in fuming HNO_3 —2 On distillation some passes over unchanged along with benzoic acid —3 Not affected by bromine —4 Boiled for some time with dilute (32 p c) H_2SO_4 it gives formic aldehyde, NH_3 , and benzoic acid —5 Heated in sealed tubes with dilute HCl it yields benzamide and formic paraldehyde

Trimethylene diamine $C_3H_7N_2$, \pm NH_2 CH_2 CH_2 CH_2 NH_2 (c 140°) Formed by heating trimethylene bromide (1 mol) and NH_3 (20 mols) in alcohol for 10 hours at 100° The liquid is decanted from NH_4Br and evaporated, treated with KOH and distilled (Fischer & Koch, *B* 17, 1799, Lellmann & Wurtthner, *A* 228, 227) Colourless mobile liquid, easily miscible with alcohol, ether, and benzene Fumes in moist air, combining with water to form a

hydrate Readily takes up CO_2 becoming solid
Condenses with benzoic aldehyde forming
 $\text{C}_6\text{H}_5(\text{N OHPh})_2$ Phenanthraquinone forms
 $\text{C}_{12}\text{H}_8\text{N}_2\text{O}_2$ a yellow powder, melting above 250°

Benzil forms $\text{CH}_2\text{<CH}_2\text{N CPh>CH}_2\text{N CPh>}$ a transparent
vitreous mass [α 76°]

Salts — $\text{B}^+\text{H}_2\text{Cl}_2$ Easily soluble prisms —
 $\text{B}^+\text{H}_2\text{Cl}_2\text{PcCl}_2$ Orange prisms — $\text{B}^+(\text{HSCN})_2$
[102°] At 140° it is partially decomposed into
trimethylene thio-urea and NH_4SCN —
 $\text{B}^+\text{H}_2\text{Br}_2$

Diacetyl derivative $\text{C}_6\text{H}_5(\text{NHAc})_2$ [79°]
White needles, v sol water, v sol alcohol,
chloroform, sl sol benzene, insol ether, petro-
leum ether (Strache, *B* 21, 2364)

Dibenzoyl derivative $\text{C}_6\text{H}_5(\text{NHBz})_2$
[148°] White crystalline powder, insol water,
m sol benzene, v sol alcohol and chloroform
On heating in a stream of HCl the product is
 $\text{C}_6\text{H}_5\text{<NH>OPh}$, an oily base which slowly
becomes crystalline and forms crystalline salts
(Hofmann, *B* 21, 2337)

Oxalyl derivative $\text{CH}_2\text{<CH}_2\text{NH CO>CH}_2\text{NH CO>}$

A sparingly soluble white powder, formed on
mixing trimethylene diamine with an alcoholic
solution of methyl oxalate It does not melt at
 250°

Derivative — $\text{V OXY TRI METHYLENE DIAMINE}$

Trimethylene di nitro di amine $\text{C}_3\text{H}_8\text{N}_4\text{O}_2$ i.e.
 $\text{NO}_2\text{NHCH}_2\text{CH}_2\text{CH}_2\text{NHNO}_2$ [67°] Formed by
heating $\text{C}_3\text{H}_8(\text{N(NO)}_2\text{CO}_2\text{Me})_2$ (v TRI METHYLENE
DICARBAMIC AMIDE) with aqueous ammonia (Franchi-
mont a Klobbie, *R T C* 7, 343) Short thick
prisms (from water or alcohol), v sol water and
alcohol, less sol ether and chloroform Boiled
with dilute (2 p c) H_2SO_4 it evolves N_2O
It has no acid reaction, and easily forms metallic
derivatives

Tetra methylene diamine $\text{C}_4\text{H}_{12}\text{N}_4$ i.e.
 $\text{NH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$ [24°] (159°) Ob-
tained by reducing ethylene cyanide in alcoholic
solution with sodium (Ladenburg, *B* 19, 780)
Identical with the ptomaine 'putrescine' (cf L
Brieger, 'Die Ptomaine,' Berlin, 1885-1886, 1,
43, 3, 101) and also with a base obtained from
a morbid urine (Udranszky a Baumann, *B* 21,
2938) Strong base, smelling like piperidine
Solutions of its salts give a crystalline pp with
iodine dissolved in KIaq but no pp with HgCl_2
or KODl_2 When shaken with aqueous NaOH
and BzCl it gives a crystalline pp of the di-
benzoyl derivative Methyl chloroformate
 ClCO_2Me forms $(\text{CH}_2)_4(\text{NH CO}_2\text{Me})_2$, which crys-
tallises in flattened needles [128°], sl sol cold
water, and is nitrated by HNO_3 , yielding
 $(\text{CH}_2)_4(\text{N(NO}_2)_2\text{CO}_2\text{Me})_2$, which crystallises from
ether and melts at 62° (Dekkers, *R T C* 9, 97)

Salts — $\text{B}^+\text{H}_2\text{Cl}_2$ Plates (from alcohol) —
 $\text{B}^+\text{H}_2\text{PcCl}_2$ Needles — Picrate Thin yellow
needles — Aurochloride [210°] Minute
thread like needles, v sol hot water (Giamicani
a Zanetti, *B* 22, 1978)

Di-benzoyl derivative $\text{O}_2\text{H}_5(\text{NHBz})_2$
[175°] (U a B), [178°] (O a Z) Plates, in-
sol water, almost insol ether, v sol hot alcohol
May be sublimed

Tetra-methylene-di-nitro-di-amine $\text{C}_4\text{H}_{12}\text{N}_4\text{O}_2$
i.e. $(\text{CH}_2)_4(\text{NH NO}_2)_2$ [168°] Got by heating
Vol. III.

$(\text{CH}_2)_4(\text{N(NO}_2)_2\text{CO}_2\text{Me})_2$ with conc NH_4Aq at
 100° and ppg by HOAc (D) Small hard crys-
tals (from water)

Penta methylene diamine $\text{C}_5\text{H}_{12}\text{N}_4$ i.e.
 $\text{NH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$ (178.5°) (L),
[178° - 180.5°] (Perkin, *C J* 55, 699) SG $\frac{1}{2}$
9174 (L), $\frac{1}{2}$ 8846, $\frac{3}{2}$ 8784 M M 7493 (P)
Formed from trimethylene cyanide by reduction
in ethereal solution with zinc and HCl , or in
alcoholic solution with sodium (Ladenburg, *B*
16, 1151, 18, 2956, 19, 780, 2585) It is iden-
tical with 'cadaverine' a base discovered by
Drieger in corpses, and among the products of
putrefaction of flesh and fish (Brieger, *B* 16,
1186, 18, 1922, 'Die Ptomaine,' Berlin, 1885,
Ladenburg, *B* 19, 2585) Found also in the
urine of a patient suffering from cystinuria, but
not in normal urine (U a B) Syrup, smelling
like piperidine, v sol water and alcohol, m sol
ether Fumes in the air Absorbs CO_2 from
the air The hydrochloride is converted by dry
distillation into NH_3 , HCl , and piperidine

Salts — $\text{B}^+\text{H}_2\text{Cl}_2$ — $\text{B}^+\text{H}_2\text{PcCl}_2$ Thick orange
prisms (from water), m sol cold water — Per-
iodide Almost black crystals (from alcohol) —
 $\text{B}^+\text{H}_2\text{Cl}_2$, 3 HgCl_2 Crystals (from hot water)
(L) — $\text{B}^+\text{H}_2\text{Cl}_2$, 4 HgCl_2 Crystals (from alcohol)
(B)

Di acetyl derivative

$\text{CH}_3(\text{CH}_2)_3\text{CH}_2\text{NHAc})_2$ Small needles (from al-
cohol) May be distilled

Di benzoyl derivative

$\text{CH}_3(\text{CH}_2)_3\text{CH}_2\text{NHBz})_2$ [130°] (above 360°) Ppd
by adding aqueous NaOH and BzCl to a solution
of the base (Udranszky a Baumann, *B* 21,
2744) Long needles and plates, v sol alcohol,
m sol ether, insol water Not affected by hot
dilute acids or alkalis

Penta methylene di nitro di amine

$\text{CH}_3(\text{CH}_2)_3\text{CH}_2\text{NH(NO}_2)_2$ Formed by treating
 $\text{CH}_3(\text{CH}_2)_3\text{CH}_2\text{N(NO)}_2\text{CO}_2\text{Me}$ with aqueous
ammonia (Franchimont a Klobbie, *R T C* 7,
343) Small oblong plates (from chloroform),
v sol water and alcohol, sol ether, sl sol
 CHCl_3 When boiled with dilute (2 p c) H_2SO_4
it evolves N_2O

Di nitroso penta methylene tetramine (so
called) $\text{C}_5\text{H}_{12}\text{N}_4\text{O}_2$ i.e. $\text{C}_5\text{H}_{12}\text{N}_4(\text{NO})_2$ [207°] (G),
[203°] (M) Formed by the action of nitrous
acid on 'hexamethylene tetramine' (Griess, *B*
21, 2738, Mayer, *B* 21, 2888) Needles (from
alcohol), v sol hot alcohol, m sol chloroform,
insol ether Not affected by boiling with zinc-
dust Dilute HCl decomposes it into nitrogen,
ammonia, and formic aldehyde

Hexa-methylene tetramine (so called)

$\text{C}_6\text{H}_{12}\text{N}_4$ Hexamethylenamine [189°] 8
(alcohol) 7 Mol w 115 (by Raoult's method)
(calc 140) (Tollens a Mayer, *B* 21, 1566)
Formed by passing dry NH_3 over heated tri-
oxy methylene (formic paraldehyde) (Butlerow,
A 115, 322, *Z* [2] 5, 278) Prepared by dis-
solving methylal in dilute H_2SO_4 , and distilling
the product with steam into a receiver containing
ammonia (Wohl, *B* 19, 1842)

Properties — Rhombohedra (from alcohol),
v sol water, chloroform, and CS_2 May be sub-
limed Scarcely attacked by sodium-amalgam
Acts nutritiously upon algae (Loew a Bokorny,
J. pr [2] 86, 272)

Reactions. — 1. Split up by boiling dilute

acids into formic aldehyde and ammonia—2 MeI at 190° forms NMeI (Tollens, *B* 17, 656)
 3 Sodium nitrite (2½ pts) added to a solution of the base (1 pt) in dilute HCl at 0° forms 'tri methylene tri nitrosamine' $C_3H_8N_3O_3$, which crystallises from alcohol in needles or prisms [106°], and is split up by warming with dilute acids into nitrogen and formic aldehyde. It exhibits Liebermann's reaction. When acetic acid is added gradually to a solution containing hexamethylene tetramine and sodium nitrite there is formed the so called di nitroso penta methylene tetramine (*v supra*), which is much less soluble in the usual menstrua than the tri methylene tri nitrosamine.

Salts— $B^+H_2Cl_2$ (dried at 100°). Long prismatic needles, *v* sol water, sl sol alcohol— $B^+H_2PtCl_4$ 4aq— B^+3AgNO_3 . White crystalline pp, formed on adding $AgNO_3$ to an aqueous solution of hexamethylene tetramine (Pratesi, *G* 13, 437). Sl sol cold, m sol hot, water, with partial reduction to silver.

Methylo iodide B^+MeI [190°]. *V* sol water, sl sol alcohol, insol ether, chloroform, and CS_2 . Gives $(B^+Me)PtCl_6$ [205°].

Ethyl iodide B^+EtI [133°].

Methylene iodide $B^+CH_2I_2$ [165°] (Wohl).

Di-bromide $C_3H_8N_2Br_2$. Insol ordinary solvents (Legler, *C C* 1888, 1604).

Tetrabromide $C_3H_8N_2Br_4$. Red crystals, obtained by the action of bromine vapour on hexamethylene tetramine (Horton, *B* 21, 1999). Decomposed by boiling water.

Di iodide $C_3H_8N_2I_2$. Obtained by adding an alcoholic solution of iodine to an aqueous solution of the base. Crystalline, *v* sl sol alcohol.

Tetra iodide $C_3H_8N_2I_4$. Obtained when excess of iodine is used. Minute brown plates, *v* sol acetone, $CHCl_3$, and CS_2 . Decomposed by boiling water.

METHYLENE DI-ISOAMYL DIOXIDE *v* FORMIC ALDEHYDE

METHYLENE - ANILINE $(C_6H_5N)_2$ *ie* $(CH_2NPh)_2$. Anhydro formaldehyde aniline [198°]. Formed by mixing aniline and crude formic aldehyde in the cold (Tollens, *B* 17, 657, 18, 3309, Kolotoff, *Bl* [2] 43, 112). White silky crystals, *v* sol chloroform and benzene, sl sol alcohol, insol water. Decomposed by boiling with water or alcohol— $B^+H_2PtCl_4$.

Methylene-aniline C_6H_5N . Formed, together with di phenyl methylene diamine and the preceding body by the action of formic aldehyde on aniline (Pratesi, *G* 14, 355). Minute crystals, decomposed by heat *v* sl sol alcohol.

Methylene-di-aniline *v* DI-PHENYL METHYLENE DIAMINE

METHYLENE-DIBENZYLAMINE $C_{10}H_{12}N_2$ *ie* $CH_2(NHCH_2Ph)_2$ [46°] (*c* 227°). Formed by the action of methylene chloride on benzyl amine at 100° (Kempff, *A* 256, 220). Rhombic prisms, insol water, *v* sol absolute alcohol and ether.

Salts— $C_{10}H_{12}N_2 \cdot 2HCl$ [242°]. Colourless monoclinic plates— B^+2HBr silky plates— B^+2HI monoclinic plates (from benzene), sl sol water and alcohol— $B^+H_2SO_4$ 2aq colourless prisms— $B^+2H_3PO_4$ [*c* 230°]. Needles— $B^+H_2Cl_4 \cdot PtCl_4$. monoclinic plates—Aurochlor.

ide $B^+H_2Cl_4 \cdot 2AuCl_3$, golden yellow needles.—Oxalate $B^+(H_2C_2O_4)_2$ [*c* 134°]—Picrate $B^+(C_6H_3(NO_2)_3OH)_2$, not stable in a hot solution, sl sol alcohol, and water.

METHYLENE BLUE *v* TETRA METHYL DIAMIDO IMIDO DI PHENYL SULPHIDE

TRIMETHYLENE BROMHYDRIN *v* BROMO PROPYL ALCOHOL

METHYLENE BROMIDE CH_2Br_2 . Dibromo methane (97° cor) (Perkin, *C J* 45, 520), (98.5° 1 V) (Henry) SG $\frac{2}{3}$ 2493 (H₂), $\frac{1}{15}$ 24985, $\frac{25}{35}$ 24775 (P) M M 8110 at 15.9°. Formed by adding bromine to methylene iodide under water (Butlerow, *A* 111, 251, Henry, *A Ch* [5] 30, 266). Formed also by heating methyl bromide with bromine at 250° (Steiner, *B* 7, 507). Found among the bromides obtained by passing into bromine the products got by passing ethylene through a red hot tube (Norton a Noyes, *Am* 8, 362). Colourless mobile liquid, insol water, sol alcohol and ether. Converted by PCl_5 at 190° into CCl_4 and CBR_4 (Holand, *A* 240, 230). When heated with 18 volts water and excess of PbO at 145° it yields ethylene glycol, traces of ethylene oxide, and $PbBr_2$ (Jeltokoff, *B* 6, 558). Slowly converted by $SbCl_5$ into methylene chloride. Potassium phenylate KOC_6H_5 yields $CH(O_2C_6H_5)_2$.

Trimethylene bromide *v* DI-BROMO PROPANE

Tetra-methylene bromide $C_4H_8Br_2$ (189°)

Formed from ethylene cyanide by successive conversion into tetra methylene diamine and $CH_2(OH)CH_2CH_2CH_2(OH)$, the glycol being then treated with HBr (Gustavson a Demjanoff, *J pr* [2] 39, 542). The yield is small.

Penta methylene bromide $C_5H_{12}Br_2$ *ie* $CH_3(CH_2CH_2Br)_2$ (205°). Formed by saturating the corresponding di oxy pentane (derived from tri methylene diamine) with HBr (*G a D*).

METHYLENE BROMO-IODIDE *v* BROMO IODO-METHANE

METHYLENE-TETRA-BUTYL-DIAMINE $CH_3(N(C_4H_9)_2)_2$ (250°). Obtained by distilling trimethylene oxide with di isobutyl amine (Ehrenberg, *J pr* [2] 36, 124)— $B^+H_2PtCl_6$ [198°]. Pale yellow powder—Aurochloride [*c* 195°]— B^+CS_2 [54°].

METHYLENE DI ISOBUTYL DIOXIDE *v* Di isobutyl ether of FORMIC ORTHALDEHYDE, vol 11 p 571

METHYLENE CAFFEIC ACID *v* vol 1 p 659

TRIMETHYLENE DICARBAMIC ACID

* $CH_2(CH_2NHCO_2H)_2$
 Methylene ether $CH_2(CH_2NHCO_2Me)_2$ [75°]

Formed by treating trimethylene diamine with methyl carbonate (Franchimont a Klobbie, *R T C* 7, 343). Oblique rhombic plates *V* sol water, alcohol, and $CHCl_3$, m sol ether, *v* sl sol benzene and light petroleum. Pure HNO_3 yields a dinitro-derivative forming tufts of needles or prisms from alcohol [90°], and this when treated with solution of ammonia gives tri-methylene dinitramine [67°].

Ethyl ether $CH_2(CH_2NHCO_2Et)_2$. Tri methylene-diurethane [42°] (210° at 30 mm). When a solution of trimethylene diamine in alcohol and ether is added to an ethereal solution of chloro formic ether $ClCO_2Et$, a pp of trimethylene diamine hydrochloride is formed, and the filtrate leaves on evaporation oily

$C_3H_6(NHCO_2Et)_2$ (Fischer & Koch, *A* 232, 225) It crystallises after some time, and separates from ether in colourless prisms *V* sol ether, alcohol, and chloroform, *sl sol* ligroin, *insol* water It dissolves in acids but is reppd by alkalis

Tetra methylene dicarbamie acid *Methyl ether* $C_4H_8(NHCO_2Me)_2$ [128°] Formed from tetra methylene diamine and $ClCO_2Me$ (Dekkers, *R T C* 9, 97) Flattened needles, *sol* warm water Converted by HNO_3 into $C_4H_8(N(NO_2)CO_2Me)_2$, which separates from ether in small brilliant crystals [62°], *v sl sol* cold water, *sl sol* ether, *sol* warm alcohol, and is converted by NH_4Aq into $C_4H_8(NHNO_2)_2$ [163°]

Pentamethylene dicarbamie acid *Methyl ether* $CH_2(CH_2CH_2NHCO_2Me)_2$ [114°] Formed by treating penta methylene diamine with methyl carbonate Fine needles (from boiling water) *V sol* hot alcohol (Franchimont & Klobbie, *R T C* 7, 343) Pure HNO_3 gives a di nitro derivative, forming small brilliant prisms [37°], and this treated with aqueous ammonia gives penta methylene dimtramine [60°] together with methyl carbamate

TRIMETHYLENE CARBOXYLIC ACID

$CH_2CHCH_2CO_2H$ *Isomeride of crotonic acid* [19°] (183°) Formed by heating ethylene malonic acid (trimethylene dicarboxylic acid) at 210° (Roder, *A* 227, 24, Perkin, *jun*, *C J* 47, 817, *B* 17, 57) White crystals, *m sol* water Has a powerful odour and a burning taste — CaA' , 6aq Needles, *v sol* water — BaA' , 2aq Needles, *v sol* water — AgA' Small needles (from hot water) Gives off a low boiling oil on distillation

Ethyl ether EtA' (134°) Formed by digesting the Ag salt with an ethereal solution of EtI Volatile oil, with pleasant odour Not affected by bromine in the cold, and only slowly attacked when boiled with bromine, HBr being given off

Trimethylene (1 1)-di-carboxylic acid so called

$CH_2CHCH_2CO_2H$, *Vinamic acid* *Ethylene malonic acid* [141°] Obtained by saponification of its ether Colourless triclinic crystals, $a b c = 0.7712 \times 1.8702$ Crystallises with aq (from water), *v e sol* water, *v sol* ether At 160° it begins to give off CO_2 , leaving trimethylene carboxylic acid It is not attacked by sodium amalgam When heated with bromine it gives off HBr slowly It combines, however, with HBr , forming bromo ethyl malonic acid (Perkin, *C J* 47, 814), and it combines with bromine when this is dissolved in chloroform (Fittig) Boiling dilute H_2SO_4 forms γ -oxy ethyl-malonic acid Alkaline $KMnO_4$ does not attack it (Buchner, *B* 23, 704)

Salts—**Ammonium salt** Four-sided plates — CuA' aq Deep blue octahedra, *sl sol* hot water At 160° it becomes a light green powder — BaA' Needles — BaH_2A' , 4aq Prismatic needles — PhA' (dried at 100°) *Insol* cold, *sl sol* hot, water — AgA' Needles, *v. sl*

sol cold water, *sl sol* hot water — $AgHA''$ Long colourless needles (from water)

Ethyl ether EtA'' (213°) *VD* 632 (calc 643) *SG* $\frac{1}{18}$ 1.0646, $\frac{2}{3}$ 1.0566 Formed by the action of ethylene bromide on sodium-malonic ether (Perkin, *jun*, *C J* 47, 812, *B* 17, 54, Fittig & Roder, *A* 227, 13) Oil Not attacked when successively treated with benzyl chloride and $NaOEt$ (Perkin, *jun*, *B* 18, 1734)

Dibromide $C_3H_4Br_2(COOH)_2$ [110°] From tri methylene di carboxylic acid and Br in chloroform (Fittig & Marburg, *B* 18, 3413)

Trimethylene (1 2)-di-carboxylic acid

Allo itaconic acid [137°] (*C a G*), [139°] (*B*)

Formation—1 By heating its anhydride with water at 140° (Conrad & Guthzeit, *B* 17, 1187) —2 From sodium propane tetracarboxylic ether $(CO_2Et)_3CNaCH_2CNa(CO_2Et)_2$, by treatment with bromine, the resulting trimethylene tetracarboxylic ether being saponified, and the free acid heated to 230°, and then distilled under 16 mm pressure the oil which passes over at 170° to 180° is heated with water at 140° (Perkin, *jun*, *B* 19, 1056, Dressel, *A* 256, 197)

Properties—Prisms, *v sol* water, alcohol, and ether Not attacked by alkaline $KMnO_4$, or by sodium amalgam (Buchner, *B* 23, 705)

Salts— CaA'' silky crystals — AgA''

(Buchner) Formed by heating trimethylene

tricarboxylic acid $CH_2 \begin{array}{c} \diagup \\ \diagdown \end{array} \begin{array}{l} CHCO_2H \\ C(CO_2H)_2 \end{array}$ or possibly

$CH_2C(CO_2H)CH(CO_2H)_2$ at 184° to 190° for a long time (*C a G*) Needles, *sl sol* ether

Trimethylene (1 2)-di-carboxylic acid

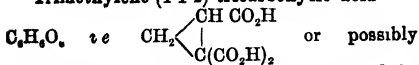

ene-1 2 di carboxylic acid Formed by saponification of the di methyl ether (Eduard Buchner, *B* 23, 705) Compact apparently rhombic crystals (from water), containing no water of crystallisation Grouped needles (from ether) Less *sol* water than the isomeric glutaric acid, but more *sol* ether Distils without splitting off water Acetyl chloride forms no anhydride Not oxidised by permanganate in alkaline solution Not reduced by sodium amalgam Chloride of iron gives a weak red brown colour

Salts—The zinc salt is more *sol* cold than hot water It crystallises in nodular groups of needles A solution of the ammonium salt gives no pp with $CaCl_2$ and $BaCl_2$, but white crystalline pps with silver and lead salts By heating the silver salt a white body sublimes in needles; probably the anhydride

Di methyl ether $C_3H_4(CO_2Me)_2$ (205°–215° at 718 mm) Formed by heating acrylo-di azo acetic ether $C_3H_4N_2(CO_2Me)_2$ for 40 minutes to 160°–185°, Saponified by boiling with aqueous potash.

Isomerides of trimethylene dicarboxylic acid
v ITACONIC, CITRACONIC, MESACONIC, and GLUTA
CONIC ACIDS

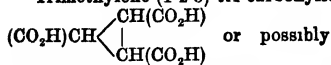

Trimethylene (1 1 2) tricarboxylic acid

$CH_2 \cdot C(CO_2H) \cdot CH(CO_2H)_2$ [184°] Formed by saponification of its ether, which is prepared by the action of $\alpha\beta$ di bromo propionic ether on di sodio malonic ether (Conrad & Guthzeit, *B* 17, 1185) Its ether is also formed by the action of a bromo acrylic ether upon sodio malonic ether $CHNa(CO_2Et)_2$ (Michael, *J pr* [2] 35, 132, 351, *Am* 9, 121) Prisms (from water) At 184°-190° it is split up into CO_2 and the dicarboxylic acid or its anhydride

Tetra-ethyl ether Et_4A'' (276°) SG 15 1 127 Colourless liquid Does not react with $NaOEt$ and $BzCl$

Trimethylene (1 2 3)-tri-carboxylic acid

$CO_2H \cdot CH \cdot C(CO_2H) \cdot CH_2 \cdot CO_2H$ [150°-153°] Formed by heating the tetra carboxylic acid (1 1 2 3) at 200° for a long time (Perkin, *B* 17, 1654, *C J* 47, 826) Colourless crystalline solid V sol water, alcohol, and acetone, sl sol benzene, chloroform, ligroin, and CS_2 On heating it yields a sublimate, probably of an anhydride

Salts — $A''Ag$, white granular pp — $A''Ca$, crystalline pp, soluble in cold water, nearly insoluble in hot The cupric salt is a beautiful light green pp, sl sol water The Ba and Pb salts are white pps

Trimethylene (1, 2, 3) tri-carboxylic acid

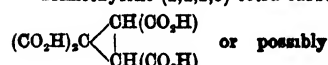

saponifying its methyl ether with alcoholic potash (Buchner, *B* 21, 2641) Small aggregates of needles (from ether), v sol alcohol and water, sl sol ether Not affected by bromine or by $KMnO_4$ Its ammonium salt crystallises in plates

Methyl ether Me_4A'' [61°] (267°) at 732 mm, (224° at 180 mm) Obtained by distilling the compound of methyl fumarate with methyl diazo acetate Needles (from alcohol or water), v sol alcohol, ether, benzene, and petroleum-ether

Anhydride $C_3H_2(CO_2H) \begin{array}{c} \diagup CO \\ \diagdown CO \end{array} O$ [189°]

(265° at 75 mm) Obtained by distilling the acid under reduced pressure Small prisms, v sol water and alcohol, m sol ether Its Pb, Ba, and Ag salts are m sol water

Trimethylene (1,1,2,3) tetra-carboxylic acid

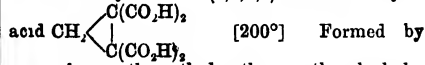

$(CO_2H)_2C \cdot C(CO_2H) \cdot CH_2 \cdot CO_2H$ [95°-100°] The tetra-ethyl ether of this acid is obtained by the action of di bromo succinic ether on di sodio-malonic ether (Perkin, *B* 17, 1652, *C J* 47, 824) Crystalline colourless solid V sol water, alcohol, ether, and acetone, sl sol ligroin and benzene. Very strong acid The acid loses CO_2

on heating to 200° giving the (1, 2, 3) tri carboxylic acid

Salts — $A''Ag$, white amorphous pp — $A''Ca$, crystalline pp, more soluble in cold water than in hot

Tetra-ethyl ether Et_4A'' , (246° at 85 mm), thick colourless oil

Tri-methylene (1,1,2,2)-tetra-carboxylic

saponifying the ethyl ether with alcoholic $KOHAq$ (Dressel, *A* 256, 196) Large shining crystals (from water) When heated to 230° it gives off $2CO_2$ and H_2O and is converted into the anhydride of trimethylene dicarboxylic acid, and from this the dicarboxylic acid itself can be obtained by heating with water to 140°

(187°) Formed by the action of bromine on the disodium compound of propane tetra carboxylic ether (Dressel, *A* 256, 194, cf Perkin, *B* 19, 1056) Long needles, v sol ether, alcohol, $CHCl_3$, and benzene (D)

Tetra-methylene carboxylic acid $C_4H_4O_6$ is

SG $\frac{1}{15}$ 1 0548, $\frac{2}{15}$ 1 0476 MM 5 048 at 18° μ_D 1 4403 at 26° Formed by heating tetra methylene dicarboxylic acid at 200°, CO_2 being given off (Perkin, *B* 16, 1795, *C J* 51, 8) Colourless oil, smelling like butyric acid, sl sol water, miscible with alcohol and ether Not attacked by bromine below 100°

Reaction—The calcium salt distilled with lime gives C_2H_4 , H_2 , CH_4 , CO , di tetramethylenyl ketone, and tetramethylenyl methyl ketone (Colman & Perkin, jun, *C J* 51, 228, *B* 19, 3112)

Salts — AgA' sparingly soluble white pp — CaA' , 5aq

Ethyl ether Et_4A' (151°) at 720 mm (P), (162°) (Freund, *B* 21, 2694)

Chloride $C_4H_4OCl_2$ (143°) (F) Obtained by heating the amide with PCl_5

Amide $C_4H_4CONH_2$ [198°] (c 240°)

Formed by heating the ammonium salt of the acid to 250° (Freund, *B* 21, 2694) Plates (from alcohol), v sol water, ether, chloroform, benzene May be sublimed Decomposed by treatment with bromine and KOH

Nitrile C_4H_4CN (150°) Formed by distilling the amide of tetra methylene carboxylic acid with phosphoric anhydride (Freund, *B* 21, 2696) Colourless oil, with pleasant odour Is converted into the amine by reducing with sodium and alcohol

Anilide $C_4H_4CONHPh$ [111°] Formed by heating the amide with aniline until no more ammonia is given off (Freund) Long needles (from alcohol), sl sol hot water

Anhydride $(C_4H_4CO)_2O$ (160°) Formed by distilling the sodium salt with the chloride of the acid (F)

Tetra-methylene (1,1)-dicarboxylic acid

$C_4H_4O_6$ is $CH_2 \begin{array}{c} \diagup CH_2 \\ \diagdown CH_2 \end{array} C(CO_2H)_2$ [156°] From the ether (Perkin, *C J* 51, 4) Monoclinic crystals (from ether), $a b c = 1.0324 \ 1.11854$, $\beta = 88^\circ 58'$. V. sol. ether and benzene, nearly

insol chloroform and ligroin, v sol water A few degrees above its melting point it splits off CO_2 , becoming tetramethylene carboxylic acid

Salts — $\text{Ag}_2\text{A}''$ — $\text{CuA}''\text{aq}$ — $\text{PbA}''\text{aq}$ — $\text{BaA}''\text{aq}$

Ethyl ether $\text{Et}_2\text{A}''$ (221°) at 720 mm SG $\frac{1}{4}$ 1.0633, $\frac{20}{4}$ 1.0405. M M 9.940 at 18.9° μ_n 1.433 Formed from malonic ether, trimethylene bromide, and NaOEt (Perkin, B 16, 1793, C J 51, 2) Oil, smelling like camphor

Tetramethylene (1,2)-di-carboxylic acid
 $\text{CH}_2\text{CH}(\text{CO}_2\text{H})$
 $\text{CH}_2\text{CH}(\text{CO}_2\text{H})$ [130°] Formed by heating

the tetra carboxylic acid to 180°–200° (Perkin, B 19, 2042, C J 51, 22) Colourless feathery crystals (from water) V sol water, alcohol, and ether, more sparingly sol benzene and ligroin By alkaline KMnO_4 it is oxidised to oxalic acid

Salts — $\text{A}''\text{Ag}_2$ heavy white pp — $\text{A}''\text{Ba}''$ sparingly soluble six sided transparent tables
Diethyl ether $\text{A}''\text{Et}_2$ (238°–242°), colourless liquid

Anhydride $\begin{array}{c} \text{CH}_2\text{CHCO} \\ \text{CH}_2\text{CHCO} \end{array} \text{O}$ [78°], colour-

less crystals, easily soluble in alcohol, sparingly in ether and benzene Formed by heating the acid to 300° Reconverted into the acid by boiling with water Heated with resorcin it gives a beautifully fluorescent condensation product

Tetramethylene (1,3) dicarboxylic acid

$\text{CO}_2\text{HCH} \begin{array}{c} \text{CH}_2 \\ \text{CH}_2 \end{array} \text{CHCO}_2\text{H}$ *Homotaconic acid* [171°] Formed by boiling its ether with fuming HClAq (Markownikoff a Krestownikoff, A 208, 333) Prisms, v sol hot water and alcohol, sl sol ether May be sublimed Does not combine with bromine, but when heated with Br it gives off HBr and CO_2 It is not reduced by sodium amalgam Does not form an anhydride Does not unite with HBr or HI

Salts — $\text{PbA}''\frac{1}{2}\text{aq}$ Crystalline crusts — AgA'' Amorphous pp, not decomposed by boiling water

Methyl ether $\text{Me}_2\text{A}''$ (220°)

Ethyl ether $\text{Et}_2\text{A}''$ (230°) Formed in very small quantity when $\text{CH}_2\text{CH}(\text{OEt})\text{CO}_2\text{Et}$ is prepared by the action of dry NaOEt on a chloro propionic ether (M a K)

Tetramethylene (1,1,2,2) - tetra - carboxylic acid $\begin{array}{c} \text{CH}_2\text{C}(\text{CO}_2\text{H})_2 \\ \text{CH}_2\text{C}(\text{CO}_2\text{H})_2 \end{array}$ [145°–150°] Obtained by

saponification of the tetra-ethyl ether, which is formed by the action of bromine upon the di sodium derivative of butane tetra carboxylic ether $\text{CH}_2\text{CNa}(\text{CO}_2\text{Et})_2$ (Perkin, B 19, 2041,

$\text{CH}_2\text{CNa}(\text{CO}_2\text{Et})_2$, C J 51, 21) Colourless crystals Easily soluble in water, alcohol, and ether, more sparingly in benzene and ligroin It evolves CO_2 at its melting point, and is converted into the di carboxylic acid

Tetramethylene (1,1,3,3) - tetracarboxylic acid *Ethyl ether*

$(\text{CO}_2\text{Et})_2\text{C} \begin{array}{c} \text{CH}_2 \\ \text{CH}_2 \end{array} \text{C}(\text{CO}_2\text{Et})_2$ Formed by the action of methylene iodide on the di sodium de-

rivative of propane tetra carboxylic ether in an alcoholic solution on the water bath (Dressel, A 256, 198) Colourless viscid oil, distilling with some decomposition between 220° and 250° at 15 mm

Pentamethylene dicarboxylic acid

$\begin{array}{c} \text{CH}_2-\text{CHCO}_2\text{H} \\ \text{CH}_2-\text{CHCO}_2\text{H} \end{array}$ [160°]

Preparation — Disodium pentane tetra carboxylic ether,

$(\text{CO}_2\text{Et})_2\text{CNaCH}_2\text{CH}_2\text{CH}_2\text{CNa}(\text{CO}_2\text{Et})_2$ is converted by Br into $\text{CH}_2 \begin{array}{c} \text{CH}_2-\text{C}(\text{CO}_2\text{Et})_2 \\ \text{CH}_2-\text{C}(\text{CO}_2\text{Et})_2 \end{array}$, which

yields pentamethylene tetracarboxylic acid on saponification, and this acid is decomposed by heat into CO_2 and pentamethylene dicarboxylic acid This is purified by conversion into its ethyl salt (Perkin, jun, C J 51, 244, B 18, 3250)

Properties — Nodules (from water) V sol hot water, alcohol, and acetic ether, sl sol ether

Salts — AgA'' Very stable white pp

Ethyl ether $\text{Et}_2\text{A}''$ (c 250°)

Anhydride $\begin{array}{c} \text{CH}_2-\text{CHCO} \\ \text{CH}_2-\text{CHCO} \end{array} \text{O}$

[64°–67°] Formed by heating the acid to 300° M sol alcohol and ether, sl sol CS_2 , insol cold, but saponified by hot, $\text{Na}_2\text{CO}_3\text{Aq}$ With resorcin and H_2SO_4 it gives the fluorescein reaction

Penta-methylene tetracarboxylic acid

$\begin{array}{c} \text{CH}_2-\text{C}(\text{CO}_2\text{H})_2 \\ \text{CH}_2-\text{C}(\text{CO}_2\text{H})_2 \end{array}$ Formed as above Sol. ether

TETRAMETHYLENE CARBOXYLIC ALDE

HYDE $\text{CH}_2 \begin{array}{c} \text{CH} \\ \text{CH}_2 \end{array} \text{CHCHO}$ (115°–117°) From

calcium tetramethylene carboxylate by distilling with calcium formate (Colman a Perkin, C J 51, 238) Oil, smelling like isobutyric aldehyde Gives a purple colour with rosamine hydrochloride which has been bleached by SO_2 , reduces ammoniacal AgNO_3Aq , combines with NaHSO_4 , reacts with hydroxylamine and with phenyl hydrazine

TRIMETHYLENE CHLORHYDRIN v

CHLORO PROPYL ALCOHOL

METHYLENE CHLORIDE CH_2Cl_2 *Di-chloro methane* Mol w 85 (41.8°) (Thorpe, C J 37, 195) SG $\frac{1}{4}$ 1.3778 (T), $\frac{15}{4}$ 1.3377, $\frac{20}{4}$ 1.3220 M M 4.313 at 11.9° (Perkin C J 45, 527) C E (0°–10°) 001335, (0°–40°) 001416 SV 65.12 H Cp 106800 (Berthe lot a Ogier, Bl [2] 36, 68)

Formation — 1 From chlorine and methyl chloride in sunlight (Regnault, A 33, 328, A Ch [2] 70, 377) — 2 By the action of zinc dust and ammonia on chloroform, the yield being very small (Perkin, C N 18, 106) — 3 By the action of chlorine on methylene iodide (Butlerow, A 107, 110, 111, 251, Z [2] 5, 276) — 4 By the action of AlCl_3 on the compound of $\text{ClCO}_2\text{CCl}_2$ with ClCO_2CH_3 (Hentschel, J pr [2] 86, 474)

Preparation — Aqueous HCl is cautiously added to a mixture of alcohol (5 vols), chloroform (1 vol), and zinc Sufficient heat is pro-

duced in the reaction to distil over much of the methylene chloride. The product is fractionally distilled (Greene, *C R* 89, 1077, *A Ph S* 18, 847, *C N* 50, 75, *A C J* 1, 522)

Properties—Oil. Like CCl_4 (but unlike CHCl_3 and CHCl_2) it exerts a poisonous action when inhaled (Regnault & Villejean, *C R* 100, 1146)

Reactions—1 Converted by ICl or ICl_2 into CHCl_3 , and hexachloro benzene. Converted by IBr into iodoform and di chloro di iodo methane (Holand, *A* 240, 234). Converted by IBr , into CBr_4 , CHBr_3 , and C_2Br_4 .—2 Heated with KI , iodine, and alcohol, it gives CH_3I , EtI , and alcohol (H).—3 Iodine at 200° gives methylene iodide (H).—4 Bromine at 170° forms CHBrCl_2 (91°), and a little CBr_2Cl_2 [38°] (150°) (Arnhold, *A* 240, 204).—5 Alcoholic NaOAc forms $\text{CH}_3(\text{OEt})$, and acetic acid (A).—6 Converted by alcoholic NH_3 at 125° into so called hexa methylene diamine (Holand, *A* 240, 225). Aqueous ammonia at 140° forms NH_4Cl , methylamine hydrochloride and formic acid (André, *C R* 102, 1474).—7 Mixed with benzene it is converted by AlCl_3 into anthracene and other products (Friedel & Crafts, *A Ch* [6] 11, 264).—8 Water at 200° forms HCl , formic acid, MeCl , and MeOH (André).—9 With H_2S it forms a crystalline compound $\text{CH}_2\text{Cl}_2(\text{H}_2\text{S})_2 \cdot 23\text{aq}$ (Forcrand, *A Ch* [5] 28, 17)

TRIMETHYLENE CHLORIDE v ω 8 Di-CHLORO PROPANE

METHYLENE CHLORO BROMIDE v CHLORO BROMO METHANE

Tri methylene chloro-bromide v CHLORO BROMO PROPANE

METHYLENE CHLORO IODIDE $\text{CH}_2\text{CH}_2\text{I}$, *Chloro iodo methane* (109°) VD 88 14 SG $\frac{11}{11}$ 2 447, $\frac{145}{145}$ 2 444. Formed by the action of ICl on methylene iodide or of iodine on $\text{IHg CH}_2\text{Cl}$ (Sakurai, *C J* 41, 361, 47, 198). Oil.

TRIMETHYLENE CYANHYDRIN v *Nitrile of γ Oxy-butyric acid*

TRIMETHYLENE CYANIDE $\text{C}_3\text{H}_6\text{N}_2$ v $\text{CH}_2(\text{CH}_2\text{CN})_2$ *Glutaronitrile* (274°) (H), (286°) (Perkin, *C J* 55, 702), (203° at 100 mm), (142° at 10 mm) (Krafft & Noerdlinger, *B* 22, 817) SG $\frac{11}{11}$ 9952, $\frac{2}{2}$ 9894 MM 5 136 (P). Formed from trimethylene bromide and alcoholic KCy (Henry, *Bl* [2] 43, 618, *C R* 100, 742). Liquid, sol water, alcohol, and chloroform, insol ether and CS_2 . Yields glutaric acid on saponification. Sodium reduces it in alcoholic solution to pentamethylene diamine and piperidine.

TRIMETHYLENE-DI ETHYL ALKINE v ETHYL OXYPROPYL AMINE

METHYLENE-ETHYL AMINE $\text{C}_3\text{H}_7\text{N}$ v EtNCH_2 (208° v) VD 2. Formed by the action of ethylamine on formic aldehyde (tri oxymethylene) (Kolotoff, *Bl* [2] 43, 112, *J R* 17, 231). Liquid, with unpleasant odour, sol cold water, but separates again on warming, v sol alcohol. HCl splits it up into ethylamine and trioxymethylene (formic paraldehyde).— $\text{B}'\text{H}_2\text{PtCl}_6$. Yellow crystalline pp. An isomeride $(\text{CH}_3)_3\text{N}, \text{Et}$, of this base is described by Lermontoff (*B*, 7, 1252) as an oil formed by heating

ethylamine with alcoholic methylene iodide at 100° — $(\text{CH}_3)_3\text{N}, \text{Et}, \text{H}_2\text{PtCl}_6$. Amorphous.

Methylene tetra ethyl-diamine $\text{C}_4\text{H}_{12}\text{N}_2$ v $\text{CH}_2(\text{NEt}_2)_2$ *Tetra ethyl-di-amido methane* (169° v) SG 10. Formed by heating trioxymethylene (formic paraldehyde) with diethylamine in sealed tubes at 100° (Kolotoff, *Bl* [2] 43, 112, Ehrenberg, *J pr* [2] 36, 118). Liquid, with peppery odour, sol water, miscible with alcohol, ether, and CHCl_3 . Split up by dilute acids, even by oxalic acid, into NH_4Et , and formic aldehyde. Combines with CS_2 , forming $\text{C}_4\text{H}_{12}\text{N}_2\text{OS}_2$.

Tetra - methylene tetra - ethyl - tetramine $\text{C}_{12}\text{H}_{28}\text{N}_4$ v $\text{CH}_2 \left\langle \begin{smallmatrix} \text{NEt CH}_2 \text{NEt} \\ \text{NEt CH}_2 \text{NEt} \end{smallmatrix} \right\rangle \text{CH}_2$. Formed by heating methylene iodide with alcoholic ethylamine at 100° (Lermontoff, *B* 7, 1252). Liquid, yielding amorphous salts— $\text{B}'\text{H}_2\text{PtCl}_6$, sol water.

METHYLENE-ETHYL PHTHALIMIDINE

$\text{C}_{11}\text{H}_{11}\text{NO}$ v $\text{C}_6\text{H}_5 \left\langle \begin{smallmatrix} \text{C}(\text{CH}_2) \\ \text{CO} \end{smallmatrix} \right\rangle \text{NEt}$. Obtained by heating $\text{C}_2\text{H}_5\text{N}_3\text{O}$, which is produced by adding aqueous ethylamine to phthalyl acetic acid (Mertens, *B* 19, 2369). Colourless oil, smelling of fresh carrots. Volatile with steam, v sol alcohol and ether.

METHYLENE DI-ETHYL DISULPHIDE

$\text{C}_4\text{H}_{10}\text{S}_2$ v $\text{CH}_3(\text{SEt})_2$ *Formic aldehyde ethyl mercaptal* *Ethyl derivative of di thio formic orthoaldehyde* (178° – 181°) SG 22 987. Formed from methylene chloride and NaSEt in alcoholic solution (Niederst, *A* 186, 391, Fromm, *A* 253, 155).

METHYLENE DI ETHYL DISULPHONE

$\text{C}_4\text{H}_{10}\text{S}_2\text{O}_2$ v $\text{CH}_3(\text{SO}_2\text{Et})_2$ (104°). Formed by the action of KMnO_4 and H_2SO_4 on $\text{CH}_3(\text{SEt})_2$ (Fromm, *A* 253, 156, cf Baumann, *B* 19, 2811). Needles, v sol water and alcohol, sol ether. Chlorine forms $\text{CCl}_2(\text{SO}_2\text{Et})_2$ [99°] crystallising in needles, while bromine produces $\text{CBr}_2(\text{SO}_2\text{Et})_2$ [132°].

Di-methylene di-ethyl trisulphone

$(\text{Et SO}_2\text{CH}_2)_2\text{SO}_2$ [149°]. Formed by treating formic aldehyde with H_2S , dissolving the product in aqueous NaOH , shaking with EtBr , and oxidising the product with KMnO_4 (Baumann, *B* 23, 1876). Sparingly soluble colourless plates.

METHYLENE-FURFURANE TRIHYDRIDE

$\text{C}_5\text{H}_8\text{O}_3$ v $\text{CH}_2 \left\langle \begin{smallmatrix} \text{CH}_2 \text{C}(\text{CH}_2) \\ \text{CH}_2 \text{O} \end{smallmatrix} \right\rangle$ (111°) at 718 mm.

Formed by the action of solid KOH on methyl bromo propyl ketone (Lupp, *B* 22, 1207). Mobile liquid, sol water. Yields a hydrate. When heated with 5 p.c. HCl aq at 100° it yields aceto propyl alcohol (methyl oxypropyl ketone). Probably identical with trimethylenyl methyl ketone of Perkin, jun (*B* 17, 1440).

TRI-METHYLENE GLYCOL $\text{C}_3\text{H}_8\text{O}_3$ v $\text{CH}_2(\text{CH}_2\text{OH})_2$ (214°) SG $\frac{1}{1}$ 10625 (Z), $\frac{186}{1}$ 10536 (F) CE (0° – 10°) 00060 SV 84 (Zander, *A* 214, 178, Lossen, *A* 254, 59). One of the products of the fermentation of glycerin by schizomycetes (Freund, *M* 2, 636).

Formation—1 By saponifying its diacetyl derivative with baryta water (Reboul, *A Ch* [5] 14, 491).—2 By warming trimethylene bromide with moist Ag_2O (Beilstein & Wiegand, *B* 15,

1497)—8 By allowing $\text{CH}_2(\text{CH}_2\text{Br})_2$ to stand for some time with a large excess of water (Niederist, *M* 3, 889)—4 By boiling trimethylene bromide with dilute aqueous K_2CO_3 (Z)

Properties—Viscid liquid, with sweet taste, miscible with water

Reactions—1 Fuming HClAq at 100° converts it into $\text{CH}_2(\text{CH}_2\text{Cl})_2$.—2 Trimethylene glycol (35 g) heated with aldehyde (12 g) at 100° yields the ethyldene derivative (*v infra*)

Di acetyl derivative $\text{CH}_2(\text{CH}_2\text{OAc})_2$ (210° cor) (c 111°) SG d 991, n_D 1.070 S 11 Formed by boiling $\text{CH}_2(\text{CH}_2\text{Br})_2$ with NaOAc (Reboul)

Ethyldene derivative $\text{C}_5\text{H}_{10}\text{O}_2$ v e
 $\text{CH}_2 \begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix} \text{CHCH}_3$ VD 3.62 (calc 3.53)

Obtained by heating the glycol with aldehyde at 100° , the yield being nearly the theoretical (Loohert, *A Ch* [6] 16, 49) Colourless liquid, with slight aldehydic odour. Dissolves in 1½ volumes of water, *v* sol alcohol and ether. Separated from its aqueous solution by CaCl_2 and by KOH . Saponified by boiling water, alkalis, and dilute acids. With PCl_5 it yields aldehyde and $\text{CH}_2(\text{CHCl})_2$

Amyldene derivative $\text{C}_6\text{H}_{10}\text{O}_2$ v e
 $\text{CH} \begin{smallmatrix} \text{CH} \\ \text{CH} \end{smallmatrix} \text{O} \text{CHCH}_2\text{C}_4\text{H}_9$ (c 165°) SG d 995 VD 5.03 (calc 4.98) Formed by heating trimethylene glycol (15 g) with valeric aldehyde (20 g) in a sealed tube at 125° . Colourless mobile liquid, *v* sol water, *v* sol alcohol and ether. Saponified by boiling water

Heptyldene derivative $\text{C}_8\text{H}_{10}\text{O}_2$ v e
 $\text{CH} \begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix} \text{CHCH}_2\text{C}_6\text{H}_{13}$ (c 216°) SG d 933 From the glycol (30 g) and heptioic aldehyde (cyanthol) at 160° (L)

Bromhydrin v Bromo propyl alcohol
TRI METHYLENE IMINE $\text{C}_3\text{H}_5\text{N}$ v e
 $\text{CH}_2 \begin{smallmatrix} \text{CH}_2 \\ \text{CH}_2 \end{smallmatrix} \text{NH}$ (65° – 80°) Formed, together with a polymeride $\text{C}_6\text{H}_9\text{N}$ (160° – 167°), from $\text{CH}_2\text{BrCH}_2\text{CH}_2\text{NH}_2$ and NaOH in the cold (Gabriel & Weiner, *B* 21, 2669) Volatile liquid, smelling like NH_3 and fuming in the air. Eagerly combines with CS_2 , $\text{B}'\text{H}\text{AuCl}_4$, $\text{B}'\text{H}\text{PtCl}_4$, $\text{B}'\text{C}_6\text{H}(\text{NO})_2\text{OH}$ (167°)

METHYLENE IODIDE CH_2I_2 *Di iodo methane* [4°] (152° at 330 mm) SG d $\frac{4}{5}$ 3.2853, $\frac{25}{4}$ 3.2656 MM 18.827 at 15° (Perkin, *C J* 45, 464)

Formation—1 By heating iodoform (4 mols) with NaOEt (9 mols) dissolved in alcohol (Butlerow, *A* 107, 110, 111, 242, *cf* Bruning, *A* 104, 187)—2 By heating chloroform with HIAq at 130° (Bljuduchov, *Z* [2] 7, 91)—3 By heating iodoform (50 g) with conc HIAq (200 g) to boiling (127°) and adding phosphorus (Lieben, *Z* 1868, 712, Baeyer, *B* 5, 1095)—4 From methylene chloride and CaI_2 at 75° (Spindler, *A* 231, 262)—5 By warming a mixture of iodoform (5 pts), water (2 pts) and reduced iron (5 pts), and fractionally distilling *in vacuo* (Cazeneuve, *C R* 98, 869)—6 An alcoholic solution of iodoform is decomposed by light, yielding CHI_3 and iodine. Oxalic acid accelerates the reaction (Mulder, *R T C* 7, 316)

Properties—Yellowish liquid, boiling with partial decomposition at 180° .

Reactions—1 Potassium has no action in the cold, but on heating it acts with explosive violence.—2 Heated with copper and water, the products are cuprous iodide and a mixture of CO , methane, CO , and ethylene (Butlerow, *A* 120, 356)—3 Silver acetate forms the diacetyl derivative of formic orthaldehyde $\text{CH}_2(\text{OAc})_2$ —4 Silver oxalate yields formic paraldehyde (trioxymethylene)—5 Chlorine yields CH_2Cl_2 —6 Bromine forms CH_2Br_2 (Arnhold, *A* 240, 207)—7 Converted by PCl_5 at 70° into methylene chloride and a trace of chloroform (Höland, *A* 240, 227)—8 Alcoholic Na_2S yields thioformic aldehyde—9 NMe_3 combines with formation of $(\text{CH}_2\text{I})\text{NMe}_3\text{I}$ —10 Aniline forms $\text{CH}_2(\text{NHPh})_2$ —11 Mercury forms IHgCH_2I (Sakurai, *C J* 37, 658)

Trimethylene iodide v Di iodo propane
DI-TETRAMETHYLENE KETONE v Di-tetramethylenyl ketone

METHYLENE-MALONIC ETHER $\text{C}_5\text{H}_8\text{O}_4$ v e
 $\text{CH C}(\text{CO}_2\text{Et})_2$ (156°) Formed by heating malonic ether with methylene iodide and NaOEt (Zelnitsky, *B* 22, 3294) Mobile liquid. Isomeric with fumaric and maleic ethers. With bromine it yields $\text{CH}_2\text{Br CBr}(\text{CO}_2\text{Et})_2$ (185° – 190° at 75–85 mm)

Polymeride $[\text{CH}_2\text{C}(\text{CO}_2\text{Et})_2]_n$ [156°] Ac companies the preceding (Z) Minute amorphous granules, insol water, *m* sol ether and alcohol. Its molecular weight determined by Raoult's method is 342 (calc 344)

DI-METHYLENE-DI-METHYL-DIAMINE $\text{C}_4\text{H}_{10}\text{N}_2$ v e (CH_2) $_2\text{N}_2\text{Me}_2$ VD ($H=1$) 41.5 (calc 43) Formed by passing a mixture of trimethylamine and hydrogen through a red hot tube (Romeny, *B* 11, 835) Crystalline. Hot dilute HClAq splits it up into formic aldehyde and methylamine— $\text{B}'\text{H PtCl}_4$

A base, boiling at about 207° , formed by the action of methylamine upon trioxymethylene (formic paraldehyde) is perhaps identical with the preceding (Kolottoff, *Bl* [2] 45, 253)

TRIMETHYLENE-HEXA-METHYL-DIAMINE $(\text{C}_2\text{H}_5)_6\text{N}_2$ Formed by heating trimethylene bromide ($\text{C}_2\text{H}_5\text{Br}$) with trimethylamine

Salts— $\text{B}'\text{H}\text{Br}_2$ aq soluble colourless needles— $\text{B}'\text{HCl}_2\text{PtCl}_4$ sparingly soluble (Roth, *B* 14, 1351)

METHYLENE METHYL BUTENYL DIKETONE $\text{CH}_3\text{COCH}_2\text{COCH}_2\text{C}_4\text{H}_7$ *Acetyl mesityl oxide* *Acetyl angelcyl methane* (205°)

Formed as a secondary product in the preparation of methylenedimethyldiketone by the action of acetone and NaOEt on acetic ether (Claisen & Ehrhardt, *B* 22, 1012, *Bl* [3] 1, 498) Oil, soluble in aqueous alkalis. Its alcoholic solution gives a red colour with FeCl_3 . Cupric acetate in concentrated solutions gives a dark green pp— CuA [123°] Crystalline, *v* sol warm alcohol and ether

METHYLENE DIMETHYL ETHER v Di-methyl ether of Ortho Formic aldehyde

METHYLENE METHYL ETHYL DIKETONE $\text{C}_5\text{H}_8\text{O}_4$ v e $\text{C}_2\text{H}_5\text{COCH}_2\text{COCH}_3$ *Acetyl propionyl methane* (158°) SG d 9538 Formed by the action of EtOAc and NaOAc upon methyl ethyl ketone (Claisen & Ehrhardt, *B* 22, 1014)— $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2$ [179°] Slender blue needles (from hot alcohol)

METHYLENE METHYL HEXYL DIKETONE $C_{16}H_{30}O_2$, ν_e CH_2 , CO , CH_2 , CO , C_6H_{13} (229°). Formed from methyl hexyl ketone, $AcOEt$, and $AcONa$ (Claisen a Ehrhardt, *B* 22, 1015) liquid— $Cu(C_{10}H_{19}O_2)_2$ (122°) Crystalline

METHYLENE DI-METHYL DIKETONE $C_8H_{14}O_2$, ν_e CH_2 , $(CO\ CH_2)_2$ *Di-acetyl methane acetyl-acetone* (136°) SG μ 987 (Combes)

Preparation—1 By slowly adding acetone (1 mol) to a mixture of acetic ether ($3\frac{1}{2}$ mols) and dry $NaOEt$ (1 mol) heated on the water bath. The product is poured into ice cold water, and the aqueous liquid mixed with $HOAc$, and cupric acetate, which ppts $Cu(C_4H_7O_2)_2$. The yield is 35 p.c. of the weight of acetone employed (Claisen, *Bl* [3] 1, 498)—2 Acetone (5.8 pts) mixed with $EtOAc$ (33 pts) is treated in the cold with sodium wire (2.3 pts). When most of the sodium is dissolved, the mixture is heated on a water bath. The product is pptd as cupric salt, the yield of ketone being 55 p.c. of the acetone employed (Claisen a Ehrhardt, *B* 22, 1009). In either case the diketone is obtained from the copper compound by adding dilute H_2SO_4 and extracting with ether—3 From the compound $C_{12}H_{21}O_4AlCl_2$ (obtained from acetyl chloride and $AlCl_3$) by adding water and extracting with chloroform. The yield is 85 p.c. of the theoretical (Combes, *A Ch* [6] 12, 211).

Properties—Colourless liquid with pleasant acetic odour, sol water, v sol aqueous HCl , miscible with alcohol, ether, and chloroform. Not attacked by PCl_5 .

Reactions—1 *Phenyl hydrazine* forms phenyl dimethyl pyrazole $CMe<\overset{CH}{NPh}>CMe$ (270.5°) (Combes, *Bl* [2] 50, 145)—2 *Potash* decomposes it into acetone and $KOAc$ —3 PCl_5 yields HCl and $C_6H_5Cl_2$ (145°), a di chloro amylene which readily combines with bromine—4 *Sodium amalgam* yields isopropyl alcohol and pinacene. But in acid solution the products of reduction by sodium amalgam are di-oxy pentane $CH_3CH(OH)CH_2CH(OH)CH_3$, and a tetrahydric alcohol analogous to pinacene—5 Conc $HIAq$ at 185° reduces it to pure n pentane (38°). At lower temperatures it forms $CH_3(CHICH_2)_2$ and $CH_3CHI(CH_2CH_2CH_3)_2$ —6 Excess of *chlorine* in sunlight yields $(COCl, CO)_2CH_2$ as final product—7 *Bromine* attacks the diketone rigorously, finally producing $(CBr, CO)_2CH_2$ (108°)—8 *Oxidation* by CrO_3 or by $KMnO_4$ yields acetic acid—9 Warm dilute *nitric acid* produces $CH_3(NO_2)_2$ and $HOAc$ —10 Dry *ammonia* passed into its ethereal solution ppts white pearly scales of the ammonium salt $CH(NH_4)(CO\ CH_3)_2$ —11 *Ethylene diamine* (2 mols) forms $C_4H_{12}(N\ CMe\ CH_2\ Ac)_2$ [111°] which yields a violet cupric salt $C_{12}H_{24}N_2O_4Cu$ [137°] and a hydrochloride $C_{12}H_{24}N_2O_4H_2Cl_2$ melting above 280°. Other diamines act in like manner (Combes, *C R* 108, 1252)—12 *Umetes* with *benzidine* (1 mol) forming a base melting at 195° (Combes)—13 *Aldehyde ammonia* ($\frac{1}{2}$ mol) at 100° forms di-acetyl tri-methyl-pyridine dihydride $C_{12}H_{17}NO_2$ [153°] (Combes, *Bl* [3] 1, 14). 14 Toluene *m* diamine at 100°, followed by H_2SO_4 , yields amido trimethyl quinoline $C_8H_{11}N_3$ [191°] (Combes, *C R* 108, 1254)—15 SO_2Cl_2 forms the chloro derivative $C_8H_9ClO_2$ (156°) (Combes, *C R* 111, 272)

Salts— $CH(NH_4)(CO\ CH_3)_2$ Pearly scales, pptd by passing NH_3 into the ethereal solution. Decomposes readily into acetone and acetamide.— Ac_2CHNa Formed by dissolving sodium in the diketone (Combes, *C R* 104, 920). White six-sided prisms, insol ether. Decomposed by water into acetone and $NaOAc$. With ethyl iodide at 140° it gives $CMEt(CO\ CH_3)_2$, a liquid boiling at 171°. Amyl iodide, in like manner, yields $C_5H_{11}CH(CO\ CH_3)_2$. The second atom of hydrogen in the methylene group may, in such compounds, be displaced by Na , and by acting with an alkyl iodide $R'I$ upon $RCN_2(CO\ CH_3)_2$, we may obtain compounds of the form $RCR'(CO\ CH_3)_2$. These reactions take place with hardly any secondary decompositions. These homologues of methylene, dimethyl diketone are decomposed by potash like the diketone itself (Combes, *A Ch* [6] 12, 211). $ClCO_2Et$ acting on the sodium derivative of methylene dimethyl diketone forms $C(OMe)_2(CO_2Et)_2$ (Claisen a Zedel, *B* 21, 3397)— $KCHAc$, White six sided prisms, sl sol alcohol, insol ether. Formed by adding $KOEt$ to an alcoholic solution of the diketone. Decomposed by hot water into acetone and $KOAc$ — $Mg(CHAc)_2$ (dried at 125°). From the diketone and magnesium carbonate (Combes, *C R* 105, 868). Transparent six sided prisms— $Al(CHAc)_3$. A by product in the rectification of the diketone, from which it may be obtained by treatment with $AlCl_3$. Small red crystals, insol water, sl sol alcohol, v sl sol ether. Can be partially volatilised. Acts on polarised light. Not decomposed by alcoholic NH_3 — $Cu(HC_2Ac)_2$ (dried at 125°). Pale blue needles, obtained by adding cupric acetate or chloride to an aqueous solution of the diketone. Insol water, the pptn being complete in dilute solutions. At 65° it forms with $COCl_2$ dissolved in benzene a crystalline compound melting at 121° (Thomas a Lefèvre, *Bl* [2] 50, 193)— $Fe(HC_2Ac)_3$. Red crystals, deposited from the ethereal extract of the red solution obtained by adding $FeCl_3$ to the diketone dissolved in water— $Pb(HC_2Ac)_2$. From the diketone and lead carbonate. Transparent crystals, sol water.

Oxim $CH_3CO\ CH_2C(NOH)CH_3$, Anhydride $CH<\overset{CMe}{O}>CMeN$ (142°) SG μ 985

Formed by the action of hydroxylamine on the diketone (Zedel, *B* 21, 2178). Colourless oil, with peculiar alkaloidal odour.

Oxim $CH_2C(NOH)CH_3$, [150°] Large transparent crystals (from ether)

Phenyl methyl hydrazide $CH_3CO\ CH_2C(N_2Ph)Me$ (Kohlrausch, *A* 253, 22)

Di-methylene di-methyl triketone $(CH_3CO\ CH_2)_2CO$ *Di-acetyl acetone* [49°] Formed from its anhydride (*vide infra*). Plates. Sl sol water, sol alkalis, warm alcohol, and ether. $FeCl_3$ gives a deep-red colour. Converted by NH_3 into oxy-di methyl pyridine [225°]

Anhydride $CO<\overset{CH\ CMe}{O}>O$ *Di methyl pyrone* [182°] (249°) Formed by the action of $HIAq$ on dehydracetic acid at a high temperature (Fest, *B* 22, 1570, *A* 257, 253). The yield is 70 p.c. of the theoretical. Crystals, v sol water. Converted by baryta, followed by HCl , into di-methylene di-methyl triketone. The carboxylic

acid of this anhydride is dehydracetic acid The dicarboxylic ether $\text{CO} \begin{smallmatrix} \diagup \text{C}(\text{CO}_2\text{Et}) \text{CMe} \\ \diagdown \text{C}(\text{CO}_2\text{Et}) \text{CMe} \end{smallmatrix} \text{O}$ [80°]

S 8 at 20° is formed by the action of COCl_2 on copper acetoacetic ether, and is converted by P_2S_5 into $\text{CS} \begin{smallmatrix} \diagup \text{C}(\text{CO}_2\text{Et}) \text{CMe} \\ \diagdown \text{C}(\text{CO}_2\text{Et}) \text{CMe} \end{smallmatrix} \text{O}$ [110°] (Conrad, *B* 19, 22, 20, 152, 2111).

Di phenyl hydrazide

$(\text{CH}_3)_2\text{C}(\text{N} \text{HPh}) \text{CH}_2 \text{CO}$ [142°]

METHYLENE METHYL PHENYL DIKETONE v BENZOYL ACETONE

METHYLENE METHYL-PHTHALIMIDINE

$\text{C}_{10}\text{H}_8\text{ON}$ & $\text{C}_6\text{H}_5 \begin{smallmatrix} \diagup \text{C}=\text{CH}_2 \\ \diagdown >\text{NMe} \\ \diagup \text{CO} \end{smallmatrix}$ Formed by heat

ing phthal methyl imidyl-acetic acid

$\text{C}_6\text{H}_5 \begin{smallmatrix} \diagup \text{CC}=\text{H CO}_2\text{H} \\ \diagdown >\text{NMe} \\ \diagup \text{CO} \end{smallmatrix}$ above 210° Colourless

crystals Volatile with steam V sol alcohol, ether, and chloroform, more sparingly sol water Very unstable body (Gabriel, *B* 18, 2454)

METHYLENE METHYL PROPYL DIKETONE $\text{C}_8\text{H}_{12}\text{O}_2$ & $\text{CH}_3\text{COCHCOCH}_3$, (175°) S G 12 9411 Formed by the action of EtOAc and NaOAc upon methyl propyl ketone (Claisen & Ehrhardt, *B* 22, 1015) Formed also from butyric ether, acetone, and NaOEt Colourless oil Boiling alkalis yield acetic and butyric acids Yields $\text{C}_6\text{H}_5\text{N}$, CHAcCOPr [55°] crystallising in yellow prisms $-\text{Cu}(\text{C}_6\text{H}_5\text{O})_2$ [161°] Blue needles

TETRA METHYL TRIMETHYLENE DI-

PYRROLE $\text{C}_{11}\text{H}_{12}\text{N}_2$ & $\begin{smallmatrix} \diagup \text{CH CMe} \\ | \\ \diagdown \text{CH CMe} \end{smallmatrix} \text{N CH}_2 \end{smallmatrix} \text{CH}_2$

[77°] Formed by heating acetyl acetone with alcoholic tri methylene diamine at 120° (Paal & Schneider, *B* 19, 3157) Crystalline

METHYLENE DI METHYL DISULPHONE

$(\text{CH}_3\text{SO})_2\text{CH}_2$ [141°] Formed from methyl mercaptan and methylene chloride, and oxidation of the product (Baumann, *B* 23, 1875) Plates On treatment with bromine water it gives $\text{CBr}_2(\text{SO}_2\text{Me})_2$ [234°]

Di methylene di methyl trisulphone

$(\text{CH}_3\text{SO}_2\text{CH}_2)_2\text{SO}_2$ [185°] Formed by saturating a solution of formic aldehyde with H_2S , extracting with ether, evaporating, dissolving the residual oil in aqueous NaOH, adding MeI, and oxidising with KMnO_4 (Baumann, *B* 23, 1872) Prisms, v sl sol cold water, alcohol, and ether Yields with bromine-water insoluble $\text{C}_6\text{H}_5\text{Br}_2\text{S}_3\text{O}_4$ [190°]

TRIMETHYLENE TRINITROSAMINE

$\text{C}_6\text{H}_5\text{N}_3\text{O}_2$ & $(\text{CH}_3\text{N NO})_3$ [106°] Formed by the action of nitrous acid upon hexamethyleneamine (F Mayer, *B* 21, 2888) Yellow needles or prisms (from alcohol), v. sol. alcohol, insol.

petroleum ether Decomposed by water with production of formic aldehyde

METHYLENE DI-OCTYL OXIDE v *Octyl ether of formic orthaldehyde*

METHYLENE OXIDE is FORMIC ALDEHYDE (q v)

METHYLENE-DI-OXY compounds v *Methylene derivatives of Di oxy compounds*

METHYLENE DI PHENYL DIAMINE v

Di PHENYL METHYLENE DIAMINE

METHYLENE DI PHENYLENE v *Di PHENYLENE METHANE*

METHYLENE DIPHENYLENE OXIDE v *Di PHENYLENE METHANE OXIDE*

METHYLENE DIPHENYL DIKETONE v

Di PHENYL METHYLENE DIKETONE

TRIMETHYLENE PHENYL KETONE v

PHENYL TRIMETHYLENE KETONE

Tetramethylene phenyl ketone v *Anhydride of PHENYL OXYBUTYL KETONE*

METHYLENE DIPHENYL OXIDE v *Di PHENYLENE METHANE OXIDE*

METHYLENE HEXAPHENYL PHOS-

PHONIUM IODIDE v *Methylene di iodide of TRI-PHENYL PHOSPHINE*

TRIMETHYLENE DI PHTHALAMIC ACID

$\text{C}_{12}\text{H}_{10}\text{N}_2\text{O}_4$ & $\text{CH}_2(\text{CH}_2\text{NH CO C}_6\text{H}_4\text{CO H})_2$ [70°-123°] Obtained by boiling trimethylene di phthalimide with potash (Gabriel, *B* 21, 2670) Crystalline Decomposed by water On boiling with aqueous HCl it is converted into phthalic acid and trimethylene-diamine

METHYLENE PHTHALIDE $\text{C}_8\text{H}_6\text{O}_2$ & a.

$\text{C}_6\text{H}_5 \begin{smallmatrix} \diagup \text{C}=\text{CH}_2 \\ \diagdown \text{C}=\text{O} \\ \diagup \text{C}=\text{O} \end{smallmatrix}$ *Anhydride of o Oxy vinyl-*

benzoic acid [60°] Formed by heating phthalyl acetic acid *in vacuo* (Gabriel, *B* 17, 2521) Small glistening crystals Soluble in hot water, easily in alcohol, ether, benzene, &c Volatile with steam It readily polymerises Combines with Br (1 mol)

Di bromide $\text{C}_6\text{H}_4 \begin{smallmatrix} \diagup \text{CBr CH}_2\text{Br} \\ \diagdown \text{C}=\text{O} \end{smallmatrix}$ [99°] Thick

glistening crystals Formed by the combination of methylene phthalide with bromine On warming with aqueous KOH it yields aceto phenone o carboxylic acid $\text{C}_6\text{H}_4(\text{CO}_2\text{H})\text{CO CH}_3$ Boiled with water it gives methylene phthalide oxide $\text{C}_8\text{H}_6\text{O}_3$ (Gabriel, *B* 17, 2524)

Methylene-phthalide oxide $\text{C}_8\text{H}_6\text{O}_3$ [146°] Long needles Formed by boiling the dibromide of methylene phthalide with water Formed also by the action of water on the product of the bromination of acetophenone o carboxylic acid (Gabriel, *B* 17, 2524)

Di chloro-methylene phthalide $\text{C}_8\text{H}_4\text{Cl}_2\text{O}_2$ & a.

$\text{C}_6\text{H}_4 \begin{smallmatrix} \diagup \text{C}=\text{CCl}_2 \\ \diagdown \text{C}=\text{O} \end{smallmatrix}$ [128°] Formed by passing

chlorine into a mixture of a chloro phenyl-acetic acid (1 pt) and HOAc (10 pts) Formed also by warming di chloro acetophenone carboxylic acid with conc H_2SO_4 (Zincke & Cooksey, *A* 255, 388) Long slender needles, gradually becoming compact when left in the liquid The needles are v sol hot alcohol, benzene, HOAc, and benzoline, the compact crystals are soluble with difficulty Alcoholic potash

converts it into di chloro acetophenone *o*-carboxylic acid Forms a dichloride

$C_6H_4 \begin{matrix} \diagup CCl_2 \\ \diagdown CCl_2 \end{matrix} \begin{matrix} \diagup O \\ \diagdown O \end{matrix}$ which crystallises in colourless prisms [94°], v sol alcohol and HOAc, and converted by alcoholic potash into phthalic acid
